takes effect
After you edit your onconfig file and restart the database server.

Usage

You can add multiple VPCLASS configuration parameter entries in your onconfig file. Each VPCLASS configuration parameter must describe a different class of virtual processors. Put each definition on a separate line.

Syntax for the VPCLASS configuration parameter

```
>>-VPCLASS--+-class-----------------------+-------------------->
            +-| cpu class |----------------+
            +-aio--+----------+--=--+-0-+--+
            |      '-autotune-'     '-1-'  |
            '-user_defined--+-------------+-'
                            '-,--noyield-'

>--+-----------------------+--+--------------------+-----------><
   '-,--num--=--number_vps-'  '-,--max--=--maximum-'
```

cpu class

```
|--cpu-------------------------------------------------------->

>--+-------------------------------------------------------+---->
   |              .-,--------------------------------.    |
   |              V                                  |    |
   '-,--aff--=--(----+-processor--------------------+-+--)-'
                     '-start -end--+--------------+-'
                                   '-/--increment-'

>--+----------+--+-------------------------+-----------------|
   '-,--noage-'  '-,--+----------+--=--+-0-+-'
                      '-autotune-'     '-1-'
```

Table 1. Options for the VPCLASS configuration parameter value

Field	Values
class	The *class* value is the name of the virtual processor class. The database server starts most virtual processors as needed. Typically, you might set the VPCLASS configuration parameter for the CPU, AIO, JVP, and user-defined virtual processor classes. The virtual processor class name is not case-sensitive. For a list of class names, see Virtual processor classes.
user_defined	The *user_defined* value is the name of a virtual processor class that you create for user-defined routines. Make sure the SINGLE_CPU_VP configuration parameter is set to 0.
autotune	Specifies whether the database server adds virtual processors for the specified class as needed to improve performance, up to the value of the **max** option, if it is included. • **autotune=0** prevents the automatic addition of virtual processors • **autotune=1** enables the automatic addition of virtual processors If the class is **cpu**, any CPU virtual processors that are automatically added do not have affinity. The **aff** option is ignored.
cpu	Specifies the CPU virtual processor class.
num	The *number_vps* value sets the number of virtual processors of the specified class that the database server starts when the database server starts. The default value is 1. The range of values for the **cpu** and **aio** virtual processor classes is 1 - 10000. The range of values for all other virtual processor classes is 0 - 10000. You can use the **onmode -p** command to add virtual processors for the class for the current session.
max	The *maximum* value specifies the maximum number of virtual processors that the database server can start for the class. The value can be any integer greater than 0. By default, the number is unlimited.
aff	On multiprocessor computers that support processor affinity, the **aff** option specifies the CPUs to which the database server binds CPU virtual processors. The operating system numbers the CPUs from 0 to one less than the number of CPUs. By default, CPU virtual processors are assigned to available processors in round-robin fashion. The **aff** option takes one or more integers: • *processor* = The CPU number to which to bind the CPU virtual processors. The CPU numbers can be listed in any order. • *start* = The beginning of a range of CPU numbers. • *end* = The end of a range of CPU numbers. • *increment* = A factor that specifies which of the CPU numbers in a range are used. For example, `aff=(1-5/2)` specifies to use CPU numbers 1, 3, and 5.
noage	Disables priority aging for CPU virtual processors, if the operating system implements priority aging. By default, priority aging is in effect.
noyield	Specifies that a user-defined virtual processor class does not yield, which allows the C UDR to yield to other threads that need access to the user-defined virtual processor class. By default, threads for user-defined virtual processors yield. A nonyielding user-defined virtual processors class runs a user-defined routine in a way that gives the routine exclusive use of the virtual processor class. User-defined routines that use a noyield virtual-processor class run serially and never yield the virtual processors to another thread. Specify only one virtual processor in a nonyielding user-defined virtual processor class, because the UDR runs on a single virtual processor until it completes and any additional virtual processors would be idle.

The options can appear in any order, separated by commas.

Use the **onmode -p** command to dynamically add or remove virtual processors for the current database session. The **onmode -p** command does not update the onconfig file.

CPU virtual processors

On a single-processor computer, allocate only one CPU virtual processor. On a multiprocessor computer, allocate a total number of CPU virtual processes plus user-defined virtual processors up to the number of CPUs on the computer.

When the database server starts, the number of CPU virtual processors is automatically increased to half the number of CPU processors on the database server computer, unless the SINGLE_CPU_VP configuration parameter is enabled.

If you include the **autotune** option, the database server adds CPU virtual processors as needed to improve performance, up to the number of CPUs on the computer.

The value of the **num** option of the VPCLASS configuration parameter for the CPU class is not updated when the database server automatically adds CPU virtual processors.

You can configure processor affinity and whether to allow aging. For example, the following entry creates four CPU virtual processors that are bound to CPU numbers 7, 8, 9, and 10, and are not affected by priority aging:

```
VPCLASS CPU,num=4,aff=(7-10),noage
```

AIO virtual processors

Use a VPCLASS configuration parameter entry for the AIO virtual processor class to specify an exact number of AIO virtual processors or to enable the database server to add AIO virtual processors as needed.

When no VPCLASS configuration parameter entry for the AIO virtual processor class is set, the number of AIO virtual processors is determined by the setting of the AUTO_AIOVPS configuration parameter and is limited to 128:

- If AUTO_AIOVPS is set to 1 (on), the number of AIO virtual processors that are initially started is equal to the number of AIO chunks.
- If AUTO_AIOVPS is set to 0 (off), the number of AIO virtual processors that are started is equal to the greater of 6 or twice the number of AIO chunks.

Java virtual processors

If you use Java™ user-defined routines or Java applications, create at least one Java virtual processor by adding a VPCLASS configuration parameter entry for the JVP virtual processor class. If you set the number of JVPs to zero, or if there is no VPCLASS parameter for the JVP class, you cannot run Java UDRs.

VP_KAIO_PERCENT configuration parameter

VP_KAIO_PERCENT is the percentage of total KAIO event resources on the system that each CPU VP will allocate.

onconfig.std value
    VP_KAIO_PERCENT 0
if not present
    0 (off)
values
    1-100
units
    Percent
takes effect
    After you edit your onconfig file and restart the database server.
    When you reset the value dynamically in your onconfig file by running the **onmode -wf** command.
    When you reset the value in memory by running the **onmode -wm** command.

Usage

VP_KAIO_PERCENT is the percentage of total KAIO event resources on the system that each CPU VP will allocate.

If you set VP_KAIO_PERCENT to 10 and the total number of KAIO events configured in the OS kernel is 50000 then each CPU VP that starts will attempt to allocate 5000 events.

A value of 0 follows legacy algorithm for allocating KAIO resources to VPs.

WSTATS configuration parameter

Use the WSTATS configuration parameter to specify whether the **onstat -g wst** command displays wait statistics for threads within the system.

Attention: You should expect a small performance impact due to the cost of gathering statistical information. Enabling the WSTATS configuration parameter for production systems is not recommended.

onconfig.std value
    WSTATS 0
range of values
    0 = Disable wait statistics
    1 = Enable wait statistics

takes effect
    After you edit your onconfig file and restart the database server.
    When you reset the value dynamically in your onconfig file by running the **onmode -wf** command.
    When you reset the value in memory by running the **onmode -wm** command.

Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters
onstat -g wst command: Print wait statistics for threads

The sysmaster database

These topics describe the **sysmaster** database and provide reference information for the *system-monitoring interface* (SMI).

These topics include:

- A description of the **sysmaster** database
- Information about how to use SMI tables
- Descriptions of the SMI tables
- A map of the documented SMI tables

For information about the ON-Bar tables, see the *IBM® Informix® Backup and Restore Guide*.

- The sysmaster Database
- The System-Monitoring Interface
- The System-Monitoring Interface Tables
  The **sysmaster** database contains many tables that you can use to monitor your system.

The sysmaster Database

The database server creates and maintains the **sysmaster** database. It is analogous to the system catalog for databases, which is described in the *IBM® Informix® Guide to SQL: Reference*. Just as a system catalog for every database managed by the database server keeps track of objects and privileges in the database, a **sysmaster** database for every database server keeps track of information about the database server.

The **sysmaster** database contains the *system-monitoring interface* (SMI) tables. The SMI tables provide information about the state of the database server. You can query these tables to identify processing bottlenecks, determine resource usage, track session or database server activity, and so on. This chapter describes these tables, which are slightly different from ordinary tables.
Warning: The database server relies on information in the **sysmaster** database. Do not change any of the tables in **sysmaster** or any of the data within the tables. Such changes could cause unpredictable and debilitating results.
The database server creates the **sysmaster** database when it initializes disk space. The database server creates the database with unbuffered logging. You cannot drop the database or any of the tables in it, and you cannot turn logging off.

As user **informix** on UNIX or a member of the **Informix-Admin** group on Windows, you can create SPL routines in the **sysmaster** database. (You can also create triggers on tables within **sysmaster**, but the database server never executes those triggers.)

Joins of multiple tables in **sysmaster** might return inconsistent results because the database server does not lock the tables during a join. You can join **sysmaster** tables with tables in other databases. However, to join **sysmaster** tables with tables in a nonlogging database, first make the nonlogging database the current database.

- The buildsmi Script
- The bldutil.sh Script

The buildsmi Script

When you bring the database server up for the first time, it runs a script called **buildsmi**, which is in the **etc** directory. This script builds the database and tables that support SMI. The database server requires approximately 1750 free pages of logical-log space to build the **sysmaster** database.

If you receive an error message that directs you to run the **buildsmi** script, a problem probably occurred while the database server was building the SMI database, tables, and views. When you use **buildsmi**, the existing **sysmaster** database is dropped and then re-created.

This script must be run as user **informix** on UNIX, or as a member of the **Informix-Admin** group on Windows, after ensuring that no connections to the sysmaster database are made during the build of the database. For example, if a Scheduler task is running when the **buildsmi** script commences, the script fails when the Scheduler attempts to access any of the sysmaster tables.

Errors issued while the **buildsmi** script runs are written (on UNIX) to the file **/tmp/buildsmi.out**, or on Windows to the file **%INFORMIXDIR%\etc\buildsmi_out.*%INFORMIXSERVER%***, where ***%INFORMIXSERVER%*** is the name of the Informix® instance.

The bldutil.sh Script

When you initialize the database server for the first time, it runs a script called **bldutil.sh** on UNIX or **bldutil.bat** on Windows. This script builds the **sysutils** database. If it fails, the database server creates an output file in the **tmp** directory. The output file is **bldutil.process_id** on UNIX and **bldutil.out** on Windows. The messages in this output file reflect errors that occurred during the script execution.

The System-Monitoring Interface

This section describes the SMI tables and how you access them to monitor the database server operation.

- Understanding the SMI Tables
- Accessing SMI tables

Understanding the SMI Tables

The SMI (system-monitoring interface) consists of tables and pseudo-tables that the database server maintains automatically. While the SMI tables appear to the user as tables, they are not recorded on disk as normal tables are. Instead, the database server constructs the tables in memory, on demand, based on information in shared memory at that instant. When you query an SMI table, the database server reads information from these shared-memory structures. Because the database server continually updates the data in shared memory, the information that SMI provides lets you examine the current state of your database server.

The SMI tables provide information about the following topics:

- Auditing
- Checkpoints
- Chunk I/O
- Chunks
- Database-logging status
- Dbspaces
- Disk usage
- Environment variables
- Extents
- Locks
- Networks
- SQL statement cache statistics
- SQL statements
- System profiling
- Tables
- User profiling
- Virtual-processor CPU usage

The data in the SMI tables changes dynamically as users access and modify databases that the database server manages.

Accessing SMI tables

Any user can use SQL SELECT statements to query an SMI table, but standard users cannot run statements other than the SELECT statement. Users who attempt to run other statements result in permission errors. The administrator can run SQL statements other than SELECT, but the results of such statements are unpredictable.

Tip: For more predictable results, query the views that are associated with each table instead of querying the tables directly.
If you query the **systabpaghdrs** table directly, you must specify an appropriate value for the `pg_partnum` parameter. The value is `pg_partnum > 1048576`. However, if you query the view that is associated with the **systabpaghdrs** table, you do not have to specify this value for the `pg_partnum` parameter.

Informix® includes the **sysadtinfo** and **sysaudit** tables. Only the user **informix** on UNIX or members of the **Informix-Admin** group on Windows can query the **sysadtinfo** and **sysaudit** tables.

You cannot use the **dbschema** or **dbexport** utilities on any of the tables in the **sysmaster** database. If you do, the database server generates the following error message:

```
Database has pseudo tables - can't build schema
```

- SELECT statements
  You can use SELECT statements on SMI tables wherever you can use SELECT against ordinary tables.
- Triggers and Event Alarms
- SPL and SMI Tables
- Locking and SMI Tables

SELECT statements

You can use SELECT statements on SMI tables wherever you can use SELECT against ordinary tables.

For example, you can use SELECT statements ordinary tables from DB-Access, in an SPL routine, with Informix® ESQL/C, and so on.
Restriction: You cannot meaningfully reference **rowid** when you query SMI tables. SELECT statements that use **rowid** do not return an error, but the results are unpredictable.

All standard SQL syntax, including joins between tables, sorting of output, and so on, works with SMI tables. For example, if you want to join an SMI table with a non-SMI table, name the SMI table with the following standard syntax:

```
sysmaster[@dbservername]:[owner.]tablename
```

Triggers and Event Alarms

Triggers based on changes to SMI tables never run. Although you can define triggers on SMI tables, triggers are activated only when an INSERT, UPDATE, or DELETE statement occurs on a table. The updates to the SMI data occur within the database server, without the use of SQL, so a trigger on an SMI table is never activated, even though the data returned by a SELECT statement indicates that it should be.

To create an event alarm, query for a particular condition at predefined intervals, and execute an SPL routine if the necessary conditions for the alarm are met.

SPL and SMI Tables

You can access SMI tables from within a SPL routine. When you reference SMI tables, use the same syntax that you use to reference a standard table.

Locking and SMI Tables

The information in the SMI tables changes based on the database server activity. However, the database server does not update the information using SQL statements. When you use SMI tables with an isolation level that locks objects, it prevents other users from accessing the object, but it does not prevent the data from changing. In this sense, all the SMI tables have a permanent Dirty Read isolation level.

The System-Monitoring Interface Tables

The **sysmaster** database contains many tables that you can use to monitor your system.

Tip: For each system-monitoring interface (SMI) table, there is a corresponding view with the same name. For the best results, query the views that are associated with tables instead of querying the underlying tables directly.
Many other tables in the **sysmaster** database are part of the system-monitoring interface but are not documented. Their schemas and column content can change from version to version. The **flags_text** table now contains more rows. To view the new rows, first drop and then re-create the **sysmaster** database.

The following table lists the SMI tables.

Table 1. SMI tables

Table	Description	Reference
sysadtinfo	Auditing configuration information	sysadtinfo
sysaudit	Auditing event masks	sysadtinfo
syscheckpoint	Checkpoint information	syscheckpoint
syschkio	Chunk I/O statistics	syschkio
syschunks	Chunk information	syschunks
syscluster	High-availability cluster information	syscluster
syscmsmsla	Connection Manager information	syscmsmsla
syscmsmtab	Connection Manager information	syscmsmtab
syscmsmunit	Information for each Connection Manager unit in a Connection Manager configuration file	syscmsmunit
syscompdicts_full	Compression dictionary information	syscompdicts_full
sysconfig	Configuration information	sysconfig
sysdatabases	Database information	sysdatabases
sysdbslocale	Locale information	sysdbslocale
sysdbspaces	Dbspace information	sysextents
sysdri	Data-replication information	sysdri
sysdual	Is a single-row table	sysdual

Table	Description	Reference
sysenv	Server startup environment	sysenv
sysenvses	Session-level environment variable	sysenvses
sysextents	Extent-allocation information	sysextents
sysextspaces	External spaces information	sysextspaces
sysha_lagtime	Secondary server lag-time statistics	sysha_lagtime Table
sysha_type	Information about connected servers	sysha_type
sysha_workload	Secondary server workload statistics	sysha_workload
sysipl	Index page logging information	sysipl
syslocks	Active locks information	syslocks
syslogs	Logical-log file information	syslogs
syslogfil	System log file information	syslogfil table
sysmgminfo	Memory Grant Manager and Parallel Data Query information	sysmgminfo
sysnetclienttype	Client type network activity	sysnetclienttype
sysnetglobal	Global network information	sysnetglobal
sysnetworkio	Network I/O	sysnetworkio table
sysonlinelog	Online log information	sysonlinelog
sysprofile	System-profile information	sysprofile
sysproxyagents	Information about all the proxy agent threads	sysproxyagents
sysproxydistributors	Proxy distributor information	sysproxydistributors
sysproxysessions	Information about sessions that use updatable secondary servers	sysproxysessions table
sysproxytxnops	Information about transactions that are run through each proxy distributor	sysproxytxnops table
sysproxytxns	Information about all of the current transactions that run through each proxy distributor	sysproxytxns table
sysptprof	Table information	sysptprof table
sysrsslog	RS secondary server information	sysrsslog
sysscblst	Memory by user	sysscblst
syssesprof	Counts of various user actions	syssesprof
syssesappinfo	Distributed Relational Database Architecture™ (DRDA) client-session information.	syssesappinfo
syssessions	Description of each user connected	syssessions
syssessiontempspaceusage	Contains information about each session's temp space usage.	syssessiontempspaceusage
syssmx	SMX (server multiplexer group) connection information	syssmx
syssmxses	SMX (server multiplexer group) session information	syssmxses
syssqexplain	SQL statement information that is enabled by the SET EXPLAIN statement	syssqexplain table
syssqltrace	SQL statement information	syssqltrace
syssqltrace_hvar	SQL statement tracing host variable information	syssqltrace_hvar
syssqltrace_info	SQL profile trace system information	syssqltrace_info
syssqltrace_iter	SQL statement iterators	syssqltrace_iter
syssrcrss	RS secondary server statistics	syssrcrss
syssrcsds	SD secondary server statistics	syssrcsds
systabnames	Database, owner, and table name for the tblspace **tblspace**	systabnames
systabpaghdrs	Page headers	None
systhreads	Wait statistics	systhreads
systrgrss	RS secondary server statistics	systrgrss
systrgsds	SD secondary server statistics	systrgsds
sysvpprof	User and system CPU used by each virtual processor	sysvpprof

- The sysutils Tables
- sysadtinfo
- sysaudit
- syschkio
  The **syschkio** system-monitoring interface table provides I/O statistics for individual chunks that the database server manages.
- syscheckpoint
- syschunks
  The **syschunks** table contains a description of each of the chunks that the database server manages.
- sysckptinfo
  The **sysckptinfo** system-monitoring interface table provides historical information about the previous twenty checkpoints.
- syscluster

- syscmsm
- syscmsmsla
- syscmsmtab
- syscmsmunit
- syscompdicts_full
  The **syscompdicts_full** table and the **syscompdicts** view provide information on all compression dictionaries. The only difference between the table and the view is that, for security purposes, the view does not contain the **dict_dictionary** column.
- sysconfig
- sysdatabases
- sysdbslocale
- sysdbspaces
  The **sysdbspaces** table contains a description of each of the storage spaces that the database server manages.
- sysdri
- sysdual
- sysenv
- sysenvses
- sysextents
- sysextspaces
- sysfeatures
- sysha_lagtime Table
  The **sysha_lagtime** table provides a history of the amount of time that it took to apply a log record on any of the secondary nodes.
- sysha_type
- sysha_workload
- sysipl
- syslocks
- syslogs
- syslogfil table
  The syslogfil table provides information about the logical log files.
- sysmgminfo
- sysnetclienttype
- sysnetglobal
- sysnetworkio table
  The **sysnetworkio** table contains information about the system network.
- sysonlinelog
- sysprofile
- sysproxyagents
- sysproxydistributors
- sysproxysessions table
  The **sysproxysessions** table contains information about each of the sessions that are using redirected-write functionality. This table is only valid on the secondary server.
- sysproxytxnops table
  The **sysproxytxnops** table contains information about each of the transactions that are running through each proxy distributor.
- sysproxytxns table
  The **sysproxytxns** table contains information about all of the current transactions that are running through each proxy distributor.
- sysptnhdr
  The **sysptrhdr** table contains information about partition headers.
- sysptprof table
  The **sysptprof** table lists information about a tblspace. Tblspaces correspond to tables.
- sysrepevtreg table
  Use the **sysrepevtreg** pseudo table to register for a pre-defined set of events from the Connection Manager.
- sysrepstats table
  Use the **sysrepstats** table to post events to Connection Manager.
- sysrsslog
- sysscblst
- syssscelem
- syssesappinfo
- syssesprof
- syssessions
- syssessiontempspaceusage
  The **syssessiontempspaceusage** table contains information about each session's temp space usage, includes both implicit and explicit temp tables.
- syssmx
- syssmxses
- syssqexplain table
  The **syssqexplain** pseudo table stores information about SQL queries.
- syssqltrace
- syssqltrace_hvar
  The **syssqltrace_hvar** table describes information about the SQL tracing host variable.
- syssqltrace_info
  The **syssqltrace_info** table describes information about the SQL profile trace system.
- syssqltrace_iter
- syssrcrss
- syssrcsds
  The **syssrcsds** table provides SD secondary server related statistics at the primary server.
- systabnames
- systhreads
- systrgrss
- systrgsds
  The **systrgsds** table provides SD secondary server related statistics at the SD secondary server.
- sysvpprof
- The SMI Tables Map

- Information from onstat in the SMI Tables

The sysutils Tables

ON-Bar uses the following tables in the **sysutils** database. For more information, see the *IBM® Informix® Backup and Restore Guide*.

Table
Description

bar_action
: Lists all backup and restore actions that are attempted against an object, except during a cold restore. Use the information in this table to track backup and restore history.

bar_instance
: Writes a record to this table for each successful backup. ON-Bar might later use the information for a restore operation.

bar_object
: Describes each backup object. This table provides a list of all storage spaces and logical logs from each database server for which at least one backup attempt was made.

bar_server
: Lists the database servers in an installation. This table is used to ensure that backup objects are returned to their proper places during a restore.

sysadtinfo

The **sysadtinfo** table contains information about the auditing configuration for the database server. For more information, see your *IBM® Informix® Security Guide*. You must be user **informix** or user **root** on UNIX or a member of the **Informix-Admin** group on Windows to retrieve information from the sysadtinfo table.

Column	Type	Description
adtmode	integer	Controls the level of auditing.
adterr	integer	Specifies how the database server behaves when it encounters an error while it writes an audit record.
adtsize	integer	Maximum size of an audit file
adtpath	char(256)	Directory where audit files are written
adtfile	integer	Number of the audit file

sysaudit

For each defined audit mask (that is, for each *username*), the **sysaudit** table contains flags that represent the database events that generate audit records. The **success** and **failure** columns represent the bitmasks that compose the audit masks. If a bit is set in both the **success** the and **failure** columns, the corresponding event generates an audit record whether or not the event succeeded.

You must be user **informix** or **user** root on UNIX or a member of the **Informix-Admin** group on Windows to retrieve information from the **sysaudit** table.

Use the **onaudit** utility to list or modify an audit mask. For information about **onaudit** and auditing, see your *IBM® Informix® Security Guide*.

Column	Type	Description
username	char(32)	Name of the mask
succ1	integer	Bitmask of the audit mask for success
succ2	integer	Bitmask of the audit mask for success
succ3	integer	Bitmask of the audit mask for success
succ4	integer	Bitmask of the audit mask for success
succ5	integer	Bitmask of the audit mask for success
fail1	integer	Bitmask of the audit mask for failure
fail2	integer	Bitmask of the audit mask for failure
fail3	integer	Bitmask of the audit mask for failure
fail4	integer	Bitmask of the audit mask for failure
fail5	integer	Bitmask of the audit mask for failure

syschkio

The **syschkio** system-monitoring interface table provides I/O statistics for individual chunks that the database server manages.

Column	Type	Description
chunknum	smallint	Chunk number
reads	integer	Number of physical reads
pagesread	integer	Number of pages read
writes	integer	Number of physical writes
pageswritten	integer	Number of pages written
mreads	integer	Number of physical reads (mirror)
mpagesread	integer	Number of pages read (mirror)
mwrites	integer	Number of physical writes (mirror)
mpageswritten	integer	Number of pages written (mirror)

syscheckpoint

The **syscheckpoint** table provides information and statistics about checkpoints.

Column	Type	Description
interval	integer	Number of checkpoints since the server was started
type	char(12)	Hard or Interval
caller	char(10)	Caller of the checkpoint
clock_time	integer	Time of day the checkpoint occurred
crit_time	float	Time spent waiting for the critical section to be released
flush_time	float	Time spent flushing pages to disk
cp_time	float	Duration from checkpoint pending until checkpoint done
n_dirty_buffs	integer	Number of dirty buffers
plogs_per_sec	integer	Number of physical log pages processed in a second
llogs_per_sec	integer	Number of logical log pages processed in a second
dskflush_per_sec	integer	Number of buffer pool pages flushed in a second
ckpt_logid	integer	Unique id of the logical log at the checkpoint
ckpt_logpos	integer	Position of the logical log at the checkpoint
physused	integer	Number of pages used in the physical log
logused	integer	Number of pages used in the logical log
n_crit_waits	integer	Number of users who had to wait to enter a critical section
tot_crit_wait	float	Duration spent waiting for all users waiting at the checkpoint critical section block
longest_crit_wait	float	Longest critical section wait
block_time	float	Duration of the checkpoint that blocked the system

syschunks

The **syschunks** table contains a description of each of the chunks that the database server manages.

In the **flags** and **mflags** columns, each bit position represents a separate flag. Thus, it might be easier to read values in the **flags** and **mflags** columns if the values are returned by the HEX function.

Table 1. The syschunks table

Column	Type	Description
chknum	smallint	Chunk number
dbsnum	smallint	Dbspace number
nxchknum	smallint	Number of the next chunk in this dbspace

Column	Type	Description
chksize	integer	Number of pages in this chunk (in units of system default page size)
offset	integer	Page offset of the chunk in its device or path
pagesize	integer	Page size (in bytes)
nfree	integer	Number of free pages in the chunk The amount of free space depends on the type of space: • dbspace = multiply the number of free pages by the system default page size of either 2 KB or 4 KB. • blobspace = multiply the number of free pages by the blobpage size. • sbspace = multiply the number of free pages by the sbpage size (which is the same as the system default page size).
is_offline	integer	1 = chunk is offline 0 = chunk is online
is_recovering	integer	1 = the chunk is being recovered 0 = the chunk is not being recovered
is_blobchunk	integer	1 = the chunk is in a blobspace 0 = the chunk is not in a blobspace
is_sbchunk	integer	1 = the chunk is an sbspace 0 = the chunk is not in an sbspace
is_inconsistent	integer	1 = the chunk is undergoing logical restore 0 = the chunk is not being restored
is_extendable	integer	1 = the chunk is extendable 0 = the chunk is not extendable
flags	smallint	The flags have the following numeric and hexadecimal values and meanings: • 16 (0x0010) = Chunk is a mirrored chunk • 32 (0x0020) = Chunk is in offline mode • 64 (0x0040) = Chunk is in online mode • 128 (0x0080) = Chunk is in recovery mode • 256 (0x0100) = Chunk is mirrored • 512 (0x0200) = Chunk is part of a blobspace • 1024 (0x0400) = Chunk is being dropped • 4096 (0x1000) = Chunk is inconsistent • 8192 (0x2000) = Chunk is extendable • 16384 (0x4000) = Chunk was added during roll forward • 32768 (0x8000) = Chunk was renamed • 65536 (0x10000) = Chunk uses big chunk page header • 131072 (0x20000) = Chunk has a tblspace tblspace extent • 262144 (0x40000) = No checkpoint was completed since this chunk was initialized (primarily for internal use)
fname	char(256)	Path name for the file or device of this chunk
mdsize	integer	Size in pages of the metadata area of a chunk that belongs to an sbspace. -1 = the chunk does not belong to an sbspace.
mfname	char(256)	Path name for the file or device of the mirrored chunk, if any
moffset	integer	Page offset of the mirrored chunk
mis_offline	integer	1 = mirror is offline 0 = mirror is online
mis_recovering	integer	1 = mirror is being recovered 0 = mirror is not being recovered
mflags	smallint	Mirrored chunk flags; values and meanings are the same as the **flags** column.
udfree	integer	Free space in pages within the user data area of a chunk that belongs to an sbspace. -1 = the chunk does not belong to an sbspace.
udsize	integer	Size in pages of the user data area of a chunk that belongs to an sbspace. -1 = the chunk does not belong to an sbspace.

sysckptinfo

The **sysckptinfo** system-monitoring interface table provides historical information about the previous twenty checkpoints.

Column	Type	Description

Column	Type	Description
ckpt_status	int	0x0011 = A checkpoint was blocked because the physical log ran out of resources. 0x0021 = A checkpoint was blocked because the logical log ran out of resources. 0x0041 = A checkpoint was blocked because transactions were too long. 0x1000 = The physical log is too small. 0x2000 = The logical log space is too small. 0x4000 = The physical log is too small for RTO.
plogs_per_S	int	Average rate of physical logging activity.
llogs_per_S	int	Average rate of logical logging activity.
dskF_per_S	int	Average rate of pages flushed to disk.
longest_dskF	int	Longest duration of time to flush the buffer pool to the disk during checkpoint processing.
dirty_pgs_S	int	Average rate of pages being modified.
sug_plog_sz	int	Suggested physical log size.
sug_llog_sz	int	Suggested logical log space size.
ras_plog_sp	int	Rate at which fast recovery can restore the physical log.
ras_llog_sp	int	Rate at which fast recovery can replay the logical log.
boottime	int	Time it takes for the server to boot shared memory and open chunks.
auto-ckpts	int	1 = on, 0 = off.
auto_lru	int	1 = on, 0 = off.
cur_intvl	int	Current® checkpoint interval id.
auto_aiovp	int	1 = on, 0 = off.

onstat -g ckp command: Print checkpoint history and configuration recommendations

syscluster

The **syscluster** system catalog table stores information about servers in a high-availability cluster. The **syscluster** table has the following columns.

Table 1. **syscluster** table information

Column	Type	Explanation
name	CHAR(128)	The name of the primary server.
role	CHAR(1)	Code to indicate whether the server is a primary server or secondary server.
syncmode	CHAR(8)	The synchronization mode between the primary server and the secondary server: sync or async.
nodetype	CHAR(8)	The type of server: HDR, RSS, or SDS.
supports_updates	CHAR(1)	Indicates whether client applications can perform update, insert, and delete operations on the secondary server (as specified by the UPDATABLE_SECONDARY configuration parameter).
server_status	CHAR(32)	Indicates the status of the secondary server.
connection_status	CHAR(32)	Indicates the connection status of the secondary server.
delayed_apply	INTEGER	Indicates whether the secondary server waits for a specified amount of time before applying logs (as specified by the DELAY_APPLY configuration parameter).
stop_apply	CHAR(24)	Indicates whether the secondary server has stopped applying log files received from the primary server (as specified by the STOP_APPLY configuration parameter).
logid_sent	INTEGER	Indicates the log ID of the most recent log page sent by the primary server to the secondary server.
logpage_sent	INTEGER	Indicates the page number of the most recent log page sent by the primary server to the secondary server.
logid_acked	INTEGER	Indicates the log ID of the most recent log page the secondary server acknowledged.
logpage_acked	INTEGER	Indicates the page number of the most recent log page the secondary server acknowledged.
ack_time	DATETIME YEAR TO SECOND	Indicates the date and time of the last acknowledged log.
sdscycle	INTEGER	Indicates the cycle number to which the primary server has advanced. Used internally by support to monitor coordination of the primary server with the secondary server.
sdscycle_acked	INTEGER	Indicates the cycle number that the shared disk secondary server has acknowledged. Used internally by support to monitor coordination of the primary server with the secondary server.

syscmsm

The **syscmsm** table is a view of the **syscmsmtab** and **syscmsmsla** tables. It contains Connection Manager service level agreement (SLA) information. The table is updated one time every five seconds.

Table 1. **syscmsm** table information

Column	Type	Description
sid	integer	Connection Manager session ID
name	char(128)	Connection Manager name
host	char(256)	Host name
unit	char(128)	Unit name
type	char(128)	Unit type
servers	char(1024)	Unit servers
foc	char(128)	Failover configuration (FOC)
flag	integer	Arbitrator flag. A value of 1 indicates that the Connection Manager Arbitrator is active. A value of 0 indicates that the Arbitrator is inactive.
sla_name	char(128)	SLA name
sla_define	char(128)	SLA definition
connections	integer	Number of connections that are made through Connection Manager

syscmsmsla

The **syscmsmsla** table contains Connection Manager service level agreement (SLA) information. The table is updated one time every five seconds.

Table 1. **syscmsmsla** table information

Column	Type	Description
address	int8	CMSLA internal address
sid	integer	Connection Manager session ID
sla_name	char(128)	SLA name
sla_define	char(128)	SLA define
connections	integer	Number of connections made through Connection Manager

syscmsmtab

The **syscmsmtab** table contains Connection Manager information.

Table 1. **syscmsmtab** table information

Column	Type	Description
address	int8	Connection Manager internal address
sid	integer	Connection Manager session ID
name	char(128)	Connection Manager name
host	char(256)	Host name
flag	integer	Arbitrator flag. A value of 1 indicates that the Connection Manager Arbitrator is active. A value of 0 indicates that the Arbitrator is inactive.

syscmsmunit

The **syscmsmunit** table contains information for each Connection Manager unit in a Connection Manager configuration file.

Table 1. **syscmsmunit** table information

Column	Type	Description

Column	Type	Description
address	int8	Connection Manager internal address
sid	integer	Connection Manager session ID
unit	char(128)	Unit name
type	char(128)	Unit type
servers	char(1024)	Unit servers
foc	char(128)	Failover configuration (FOC)
flag	integer	Arbitrator flag. A value of 1 indicates that the Connection Manager Arbitrator is active. A value of 0 indicates that the Arbitrator is inactive.

syscompdicts_full

The **syscompdicts_full** table and the **syscompdicts** view provide information on all compression dictionaries. The only difference between the table and the view is that, for security purposes, the view does not contain the **dict_dictionary** column.

Only user **informix** can retrieve information from the **syscompdicts_full** table. The **syscompdicts** view is not restricted to user **informix**.

The following table shows the information that the **syscompdicts_full** table and the **syscompdicts** view provide for each compression dictionary.

Table 1. Compression Dictionary Information

Column	Type	Description
dict_partnum	integer	Partition number to which the compression dictionary applies
dict_code_version	integer	Version of the code that is creating the compression dictionary 1 is the first version.
dict_dbsnum	integer	Number of the dbspace that the dictionary resides in
dict_create_timestamp	integer	Timestamp that shows when the dictionary was created
dict_create_loguniqid	integer	Unique ID for the logical log that was active when the dictionary was created
dict_create_logpos	integer	Position within the logical log when the dictionary was created
dict_drop_timestamp	integer	Timestamp that shows when the dictionary was dropped.
dict_drop_loguniqid	integer	Unique ID for the logical log that was created when the dictionary was dropped.
dict_drop_logpos	integer	Position within the logical log when the dictionary was dropped.
dict_dictionary	byte	Compression dictionary binary object This column is not included in the **syscompdicts** view.

Sample syscompdicts information

A row of information in the **syscompdicts** view could displays columns containing this information:

```
dict_partnum        1048939
dict_code_version   1
dict_dbsnum         1
dict_create_times+  1231357656
dict_create_logun+  11
dict_create_logpos  1695768
dict_drop_timesta+  0
dict_drop_loguniq+  0
dict_drop_logpos    0
```

You can use an UNLOAD statement to unload the compression dictionary to a compression dictionary file, as follows:

```
UNLOAD TO 'compression_dictionary_file'
   SELECT * FROM sysmaster:syscompdicts_full;
```

sysconfig

The **sysconfig** table describes the effective, original, and default values of the configuration parameters. For more information about the ONCONFIG file and the configuration parameters, see Database configuration parameters.

Column	Type	Description
cf_id	integer	Unique numeric identifier

Column	Type	Description
cf_name	char(128)	Configuration parameter name
cf_flags	integer	Reserved for future use
cf_original	char(256)	Value in the ONCONFIG file at boot time
cf_effective	char(256)	Value currently in use
cf_default	char(256)	Value provided by the database server if no value is specified in the ONCONFIG file

sysdatabases

The **sysdatabases** view describes each database that the database server manages.

Table 1. **sysdatabases** view information

Column	Type	Description	
name	char(128)	Database name	
partnum	integer	The partition number (tblspace identifier) for the systables table for the database	
owner	char(32)	User ID of the creator of the database	
created	date	Date created	
is_logging	integer	1 If logging is active, 0 if not	
is_buff_log	integer	1 If buffered logging, 0 if not	
is_ansi	integer	1 If ANSI/ISO-compliant, 0 if not	
is_nls	integer	1 If GLS-enabled, 0 if not	
is_case_insens	integer	1 If case-insensitive for NCHAR and NVARCHAR columns, 0 if not	
flags	smallint	Logging flags (hex values)	
		0	No logging
		1	Unbuffered logging
		2	Buffered logging
		4	ANSI/ISO-compliant database
		8	Read-only database
		10	GLS database
		20	Checking of the logging mode of **syscdr** database bypassed
		100	Changed status to buffered logging
		200	Changed status to unbuffered logging
		400	Changed status to ANSI/ISO compliant
		800	Database logging turned off
		1000	Long ID support enabled

sysdbslocale

The **sysdbslocale** table lists the locale of each database that the database server manages.

Table 1. **sysdbslocale** table information

Column	Type	Description
dbs_dbsname	char(128)	Database name
dbs_collate	char(32)	The locale of the database

sysdbspaces

The **sysdbspaces** table contains a description of each of the storage spaces that the database server manages.

Table 1. **sysdbspaces** table information

Column	Type	Description
dbsnum	smallint	Space number
name	char(128)	Space name
owner	char(32)	User ID of owner of the space
fchunk	smallint	Number of the first chunk in the space
nchunks	smallint	Number of chunks in the space
create_size	decimal	The minimum size of a chunk that can be created for this space using the storage pool.
extend_size	decimal	The minimum size by which a chunk in this storage space can be extended, either manually or automatically.
pagesize	integer	Page size
is_mirrored	integer	1 = The space is mirrored 0 = The space is not mirrored
is_blobspace	integer	1 = The space is a blobspace 0 = The space is not a blobspace
is_sbspace	integer	1 = The space is an sbspace 0 = The space is not an sbspace
is_temp	integer	1 = The space is a temporary dbspace 0 = The space is not a temporary dbspace
is_encrypted	integer	1 = The space is encrypted 0 = The space is not encrypted
flags	smallint	Each bit position represents a separate flag. Thus, it might be easier to read values in this column if you return the values with the HEX function. • 1 (0x0001) = The space has no mirror • 2 (0x0002) = The space uses mirroring • 4 (0x0004) = Mirroring is disabled • 8 (0x0008) = The space is newly mirrored • 16 (0x0010) = The space is a blobspace • 32 (0x0020) = The blobspace is on removable media • 128 (0x0080) = The blobspace has been dropped • 512 (0x0200) = The space is being recovered • 1024 (0x0400) = The space has been physically recovered • 2048 (0x0800) = The space is in logical recovery • 32768 (0x8000) = The space is an sbspace

Related reference:
DISK_ENCRYPTION configuration parameter

sysdri

The **sysdri** table provides information about the High-Availability Data-Replication status of the database server.

Column	Type	Description
type	char(50)	High-Availability Data Replication type Possible values: • primary • secondary • standard • not initialized
state	char(50)	State of High-Availability Data Replication Possible values: • off • on • connecting • failure • read-only
name	char(128)	The name of the other database server in the High-Availability Data-Replication pair
intvl	integer	The High-Availability Data-Replication interval
timeout	integer	The High-Availability Data-Replication timeout value for this database server
lostfound	char(256)	The pathname to the lost-and-found file

sysdual

The **sysdual** table returns exactly one column and one row.

Column	Type	Description
dummy	char(1)	Dummy columns returning "X"

sysenv

The **sysenv** table displays the startup environment settings of the database server.

Column	Type	Description
env_id	integer	Identifier variable number
env_name	char(128)	Environment variable name
env_value	char(512)	Environment variable value

sysenvses

The **sysenvses** table displays the environment variable at the session level.

Column	Type	Description
envses_sid	integer	Session id
envses_id	integer	Identifier variable number
envses_name	char(128)	Session environment variable name
envses_value	char(512)	Session environment variable value

sysextents

The **sysextents** table provides information about extent allocation.

Column	Type	Description
dbsname	char(128)	Database name
tabname	char(128)	Table name
chunk	integer	Chunk number
offset	integer	Number of pages into the chunk where the extent begins
size	integer	Size of the extent, in pages

sysextspaces

The sysextspaces table provides information about external spaces. Indexes for the **id** column and the **name** column allow only unique values.

Column	Type	Description
id	integer	External space ID
name	char(128)	External space name
owner	char(32)	External space owner
flags	integer	External space flags (reserved for future use)
refcnt	integer	External space reference count.
locsize	integer	Size of external space location, in bytes
location	char (256)	Location of external space

sysfeatures

The **sysfeatures** view provides general information about various features of the Informix® database server instance. The **sysfeatures** view is created from an internal table named **syslicenseinfo**, which is stored permanently on the disk. When the database server instances are initialized, the table is pre-allocated with a fixed size which allows tracking of 260 weeks of data. The data wraps every five years.

Metrics are sampled every 15 minutes and only the highest values during the particular week are stored. Each row in the table contains data only for the specific week it represents.

Column	Type	Description
week	smallint	The week that the information was recorded.
year	smallint	The year that the information was recorded.
version	char(12)	The Informix server version.
max_cpu_vps	smallint	The maximum number of CPU virtual processors.
max_vps	smallint	The maximum number of virtual processors.
max_conns	integer	The maximum number of concurrent physical connections on a standalone or high-availability cluster primary server instance.
max_sec_conns	integer	The maximum number of concurrent physical connections on an HDR secondary or RS secondary server instance.
max_sds_clones	smallint	The maximum number of SD secondary server instances connected to the primary server.
max_rss_clones	smallint	The maximum number of RS secondary server instances connected to the primary server.
total_size	integer	The maximum disk space allocated in all chunks (in megabytes).
total_size_used	integer	The maximum disk space used in all chunks (in megabytes).
max_memory	integer	The maximum memory allocated in all segments (in megabytes).
max_memory _used	integer	The maximum memory used in all segments (in megabytes).
is_primary	integer	Indicates whether the server was a primary server in a particular week; 1 = yes, 0 = no.
is_secondary	integer	Indicates whether the server was an HDR secondary server in a particular week; 1 = yes, 0 = no.
is_sds	integer	Indicates whether the server was an SD secondary server in a particular week; 1 = yes, 0 = no (not implemented; always 0).
is_rss	integer	Indicates whether the server was an RS secondary server in a particular week; 1 = yes, 0 = no.
is_er	integer	Indicates whether the server was an enterprise replication server in a particular week; 1 = yes, 0 = no.
is_pdq	integer	Indicates whether the PDQ feature was used on the server instance in the particular week; 1 = yes, 0 = no.

sysha_lagtime Table

The **sysha_lagtime** table provides a history of the amount of time that it took to apply a log record on any of the secondary nodes.

The **sysha_lagtime** table contains a history of the last 20 samplings performed for a particular secondary server.

Table 1. **sysha_lagtime** table information

Column	Type	Description
lt_secondary	CHAR(128)	Name of secondary server
lt_time_last_update	INTEGER	Time at which log record was last updated
lt_lagtime_1	FLOAT	Amount of time required to apply log record for the most recent five-second interval
lt_lagtime_2	FLOAT	Amount of time required to apply log record for the second most recent five-second interval
lt_lagtime_3	FLOAT	Amount of time required to apply log record for the third most recent five-second interval
lt_lagtime_4	FLOAT	Amount of time required to apply log record for the fourth most recent five-second interval
lt_lagtime_5	FLOAT	Amount of time required to apply log record for the fifth most recent five-second interval
lt_lagtime_6	FLOAT	Amount of time required to apply log record for the sixth most recent five-second interval
lt_lagtime_7	FLOAT	Amount of time required to apply log record for the seventh most recent five-second interval
lt_lagtime_8	FLOAT	Amount of time required to apply log record for the eighth most recent five-second interval
lt_lagtime_9	FLOAT	Amount of time required to apply log record for the ninth most recent five-second interval
lt_lagtime_10	FLOAT	Amount of time required to apply log record for the tenth most recent five-second interval
lt_lagtime_11	FLOAT	Amount of time required to apply log record for the eleventh most recent five-second interval
lt_lagtime_12	FLOAT	Amount of time required to apply log record for the twelfth most recent five-second interval

Column	Type	Description
lt_lagtime_13	FLOAT	Amount of time required to apply log record for the thirteenth most recent five-second interval
lt_lagtime_14	FLOAT	Amount of time required to apply log record for the fourteenth most recent five-second interval
lt_lagtime_15	FLOAT	Amount of time required to apply log record for the fifteenth most recent five-second interval
lt_lagtime_16	FLOAT	Amount of time required to apply log record for the sixteenth most recent five-second interval
lt_lagtime_17	FLOAT	Amount of time required to apply log record for the seventeenth most recent five-second interval
lt_lagtime_18	FLOAT	Amount of time required to apply log record for the eighteenth most recent five-second interval
lt_lagtime_19	FLOAT	Amount of time required to apply log record for the nineteenth most recent five-second interval
lt_lagtime_20	FLOAT	Amount of time required to apply log record for the twentieth most recent five-second interval

sysha_type

The **sysha_type** table is a single row table that is used to describe the type of server that is connected.

Table 1. **sysha_type** table information

Column	Type	Description
ha_type	integer	Server type (see table below)
ha_primary	char(128)	Server name (see table below)

Table 2. Descriptions for the values in the **sysha_type** table. This table describes the values in the **sysha_type** table.

Value of *ha_type*	Value of *ha_primary*	Description
0	NULL	Not part of a high-availability environment
1	*<primary server name>*	Primary server
2	*<primary server name>*	HDR secondary server
3	*<primary server name>*	SD secondary server
4	*<primary server name>*	RS secondary server

sysha_workload

The **sysha_workload** table contains workload statistics on each of the secondary servers.

Table 1. **sysha_workload** table information

Column	Type	Description
wl_secondary	char(128)	Name of secondary server
wl_time_last_update	integer	Time at which workload last updated
wl_type	char(12)	This row contains the ready queue size, user CPU time, and system CPU time
wl_workload_1	float	Most recent workload activity
wl_workload_2	float	Second most recent workload activity
wl_workload_3	float	Third most recent workload activity
wl_workload_4	float	Fourth most recent workload activity
wl_workload_5	float	Fifth most recent workload activity
wl_workload_6	float	Sixth most recent workload activity
wl_workload_7	float	Seventh most recent workload activity
wl_workload_8	float	Eighth most recent workload activity
wl_workload_9	float	Ninth most recent workload activity
wl_workload_10	float	Tenth most recent workload activity
wl_workload_11	float	Eleventh most recent workload activity
wl_workload_12	float	Twelfth most recent workload activity
wl_workload_13	float	Thirteenth most recent workload activity
wl_workload_14	float	Fourteenth most recent workload activity
wl_workload_15	float	Fifteenth most recent workload activity

Column	Type	Description
wl_workload_16	float	Sixteenth most recent workload activity
wl_workload_17	float	Seventeenth most recent workload activity
wl_workload_18	float	Eighteenth most recent workload activity
wl_workload_19	float	Nineteenth most recent workload activity
wl_workload_20	float	Twentieth most recent workload activity

sysipl

The **sysipl** table provides information about the status of index page logging at the primary server.

Table 1. **sysipl** table information

Column	Type	Description
ipl_status	integer	Index page logging status
ipl_time	integer	Time at which index page logging was enabled

syslocks

The **syslocks** table provides information about all the currently active locks in the database server.

Table 1. **syslocks** table information

Column	Type	Description	
dbsname	char(128)	Database name	
tabname	char(128)	Table name	
rowidlk	integer	Real rowid, if it is an index key lock	
keynum	smallint	Key number of index key lock	
type	char(4)	Type of lock	
		B	Byte lock
		IS	Intent shared lock
		S	Shared lock
		XS	Shared key value held by a repeatable reader
		U	Update lock
		IX	Intent exclusive lock
		SIX	Shared intent exclusive lock
		X	Exclusive lock
		XR	Exclusive key value held by a repeatable reader
owner	integer	Session ID of the lock owner	
waiter	integer	Session ID of the user waiting for the lock. If more than one user is waiting, only the first session ID appears.	

syslogs

The **syslogs** table provides information about space use in logical-log files. In the **flags** column, each bit position represents a separate flag. For example, for a log file, the **flags** column can have flags set for both current log file and temporary log file. Thus, it might be easier to read values in the **flags** column if the values are returned using the HEX function.

Table 1. **syslogs** table information

Column	Type	Description
number	smallint	Logical-log file number
uniqid	integer	Log-file ID
size	integer	Number of pages in the log file
used	integer	Number of pages used in the log file
is_used	integer	1 If file is used, 0 if not

Column	Type	Description		
is_current	integer	1 If file is the current file, 0 if not		
is_backed_up	integer	1 If file has been backed up, 0 if not		
is_new	integer	1 If the log has been added since the last level-0 dbspace backup, 0 if not		
is_archived	integer	1 If file has been placed on the backup tape, 0 if not		
is_temp	integer	1 If the file is flagged as a temporary log file, 0 if not		
flags	smallint	Flags	Hexadecimal	Meaning
		1	0x01	Log file is in use
		2	0x02	File is current log file
		4	0x04	Log file has been backed up
		8	0x08	File is newly added log file
		16	0x10	Log file has been written to dbspace backup media
		32	0x20	Log is a temporary log file

syslogfil table

The syslogfil table provides information about the logical log files.

Table 1. Information about the columns in the syslogfil table.

Column	Type	Description
address	int8	Memory address of the logfile structure
number	small integer	Log file number
flags	integer	For a description of the values and their meanings, see the **Flag values** section below.
fillstamp	integer	Internal timestamp when the log file was filled
filltime	integer	UNIX time when the log file was filled
uniqid	integer	Unique ID for the log file
chunk	integer	Number of the chunk that contains the log file
offset	integer	Page offset in the chunk where log file begins
size	integer	Total number of pages in the log file
used	integer	Number of pages used in the log file

Flag values

The flag values correspond to many of the flag values for the **onstat -l** command.

Hexadecimal	Onstat -l flag value	Meaning
0x1	U	Log file is in use
0x2	C	File is current log file
0x4	B	Log file has been backed up
0x8	A	File is a newly added log file
0x20	None	A temporary log file
0x40	D	Log file will be dropped after the file is archived
0x4000	L	Log file contains the last checkpoint written

sysmgminfo

The **sysmgminfo** table provides an overview of the Memory Grant Manager (MGM) and Parallel Data Query (PDQ) information.

Table 1. **sysmgminfo** table information

Column	Type	Description
max_query	integer	Maximum number of active queries allowed
total_mem	integer	Total MGM memory
avail_mem	integer	Free MGM memory

Column	Type	Description
total_seq	integer	Total number of sequential scans
avail_seq	integer	Unused sequential scans
active	integer	Number of active MGM queries
ready	integer	Number of ready MGM queries
min_free_mem	integer	Minimum free MGM memory
avg_free_mem	float	Average free MGM memory
std_free_mem	float	Standard free MGM memory
min_free_seq	integer	Minimum free MGM sequential scans
avg_free_seq	float	Average free MGM sequential scans
std_free seq	float	Standard free MGM sequential scans
max_active	integer	Maximum active MGM SQL operations
cnt_active	integer	Number of active MGM SQL operations
avg_active	float	Average active MGM SQL operations
std_active	float	Standard active MGM SQL operations
max_ready	integer	Maximum ready MGM SQL operations
cnt_ready	integer	Number of ready MGM SQL operations
avg_ready	float	Average ready MGM SQL operations
std_ready	float	Standard ready MGM SQL operations

sysnetclienttype

The **sysnetclienttype** table provides an overview of the network activity for each client type.

Column	Type	Description
nc_cons_allowed	integer	Whether or not connections are allowed
nc_accepted	integer	Number of connections that were accepted
nc_rejected	integer	Number of network connections that were rejected
nc_reads	int8	Number of network reads for this client type
nc_writes	int8	Number of network writes for this client type
nc_name	char(18)	Name of the client type

sysnetglobal

The **sysnetglobal** table provides an overview of the system network.

Column	Type	Description
ng_reads	int8	Number of network reads
ng_writes	int8	Number of network writes
ng_connects	int8	Number of network connections
ng_his_read_count	int8	Number of network reads by users who have disconnected **ng_his_read_bytes**
ng_his_read_bytes	int8	Data transferred to the server by users who have disconnected
ng_his_write_count	int8	Number of network writes by users who have disconnected
ng_his_write_bytes	int8	Data transferred to the client by users who have disconnected
ng_num_netscbs	integer	Number of network subscribers
ng_max_netscbs	integer	Maximum number of network subscribers
ng_free_thres	integer	Threshold for the maximum number of freed buffers in the buffer list
ng_free_cnt	integer	Number of times the ng_free_thres limit has been reached
ng_wait_thres	integer	Threshold for the maximum number of buffers that can be held in the buffer list for one connection
ng_wait_cnt	integer	Number of times the ng_wait_thres limit has been reached
ng_pvt_thres	integer	Threshold for the maximum number of freed buffers in the private buffer queue

Column	Type	Description
ng_netbuf_size	integer	Size of the transport network buffers
ng_buf_alloc	integer	Number of network buffers allocated
ng_buf_alloc_max	integer	Maximum value of allocated network buffers
ng_netscb_id	integer	Next netscb id

sysnetworkio table

The **sysnetworkio** table contains information about the system network.

Column	Type	Description
net_id	integer	Netscb id
sid	integer	Session id
net_netscb	int8	Netscb prt
net_client_type	integer	Client type Int
net_client_name	char(12)	Client protocol name
net_read_cnt	int8	Number of network reads
net_write_cnt	int8	Number of network writes
net_open_time	integer	Time this session connected
net_last_read	integer	Time of the last read from the network
net_last_write	integer	Time of the last write from the network
net_stage	integer	Connect / Disconnect / Receive
net_options	integer	Options from sqlhosts
net_protocol	integer	Protocol
net_type	char(10)	Type of network protocol
net_server_fd	integer	Server fd
net_poll_thread	integer	Poll thread

sysonlinelog

The **sysonlinelog** table provides a view of the information stored in the online.log file.

Column	Type	Description
offset	int8	File offset
next_offset	int8	Offset to the next message
line	char(4096)	Single line of text from the file

sysprofile

The **sysprofile** table contains profile information about the database server.

Column	Type	Description
name	char(13)	Name of profiled event. (See table that follows for a list of possible events.)
value	integer	Value of profiled event. (See table that follows for a list of possible events.)

The following table lists the events that, together with a corresponding value, make up the rows of the **sysprofile** table.

Events Profiled in sysprofile	Description
dskreads	Number of actual reads from disk
bufreads	Number of reads from shared memory
dskwrites	Actual number of writes to disk
bufwrites	Number of writes to shared memory

Events Profiled in sysprofile	Description
isamtot	Total number of calls
isopens	isopen calls
isstarts	isstart calls
isreads	isread calls
iswrites	iswrite calls
isrewrites	isrewrite calls
isdeletes	isdelete calls
iscommits	iscommit calls
isrollbacks	isrollback calls
ovlock	Overflow lock table
ovuser	Overflow user table
ovtrans	Overflow transaction table
latchwts	Latch request waits
bufwts	Buffer waits
lockreqs	Lock requests
lockwts	Lock waits
ckptwts	Checkpoint waits
deadlks	Deadlocks
lktouts	Deadlock time-outs
numckpts	Number checkpoints
plgpagewrites	Physical-log pages written
plgwrites	Physical-log writes
llgrecs	Logical-log records
llgpagewrites	Logical-log writes
llgwrites	Logical-log pages written
pagreads	Page reads
pagwrites	Page writes
flushes	Buffer-pool flushes
compress	Page compresses
fgwrites	Foreground writes
lruwrites	Least-recently used (LRU) writes
chunkwrites	Writes during a checkpoint
btradata	Read-ahead data pages read through index leaf node
btraidx	Read-ahead data pages read through index branch or root node
dpra	Data pages read into memory with read-ahead feature
rapgs_used	Read-ahead data pages that user used
seqscans	Sequential scans
totalsorts	Total sorts
memsorts	Sorts that fit in memory
disksorts	Sorts that did not fit in memory
maxsortspace	Maximum disk space used by a sort

sysproxyagents

The **sysproxyagents** table contains information about all proxy agent threads. Proxy agent threads run on the primary server and accept requests from secondary servers to process DML operations. The primary server also contains a proxy distributor that handles secondary server updates. Secondary servers determine how many instances of the proxy distributor to create based on the UPDATABLE_SECONDARY setting in the secondary server's ONCONFIG file.

Column	Type	Description
tid	integer	Transaction ID of the proxy agent thread running on the primary server. This ID is created by the proxy distributor to handle work from the secondary server session.
flags	integer	Flags of the proxy agent thread.

Column	Type	Description
proxy_id	integer	ID of the proxy distributor on behalf of the currently executing proxy agent thread (TID).
source_session_id	integer	ID of the user's session on the secondary server.
proxy_txn_id	integer	Number of the current transaction. These numbers are unique to the proxy distributor.
current_seq	integer	The sequence number of the current operation in the current transaction.
sqlerrno	integer	Error number of any SQL error (or 0 on success)
iserrno	integer	Error number of any ISAM/RSAM error (or 0 on success)

sysproxydistributors

The **sysproxydistributors** table contains information about the proxy distributors.

On the primary server, this table contains information about all of the proxy distributors in a high-availability cluster. On a secondary server, this table contains information about only those proxy distributors that are assigned to process updates to the secondary server.

Column	Type	Description
node_name	char	Name of the secondary server as it is known by the primary server (for example, INFORMIXSERVER, HA_ALIAS, and so on).
proxy_id	integer	ID of the proxy distributor. These IDs are unique within a high-availability cluster.
transaction_count	integer	Number of transactions currently being processed by the proxy distributor.
hot_row_total	integer	Total number of hot rows ever handled by the proxy distributor. A hot row is a row on a secondary server that is updated multiple times by more than one client. When a row is updated multiple times, the secondary server reads the before image from the primary server by placing an update lock on the row if the most recent update operation from a different session is not replayed on the secondary server.

sysproxysessions table

The **sysproxysessions** table contains information about each of the sessions that are using redirected-write functionality. This table is only valid on the secondary server.

The following table provides information about the columns in the **sysproxysessions** table:

Column	Type	Description
session_id	integer	ID of a user's session on the secondary server.
proxy_id	integer	ID of the proxy distributor on behalf of which the proxy agent thread (TID) is running
proxy_tid	integer	Transaction ID of the proxy agent thread running on the primary server. This ID is created by the proxy distributor to handle work from the secondary server session.
proxy_txn_id	integer	Number of the current transaction. These numbers are unique to the proxy distributor.
current_seq	integer	The sequence number of the current operation in the current transaction.
pending_ops	integer	The number of operations buffered on the secondary server that have not yet been sent to the primary server.
reference_count	integer	Indicates the number of threads (for example, sqlexec, sync reply, recovery, and so on) that are using the information for this transaction. When reference_count equals 0, the transaction processing has completed (either successfully or unsuccessfully).

sysproxytxnops table

The **sysproxytxnops** table contains information about each of the transactions that are running through each proxy distributor.

On the primary server, this table contains information about all of the proxy distributors in the high-availability cluster. On a secondary server, this table only contains information about the proxy distributors used to process updates to the secondary server.

The following table provides information about the columns in the **sysproxytxnops** table:

Column	Type	Description
proxy_id	integer	ID of the proxy distributor. These IDs are unique within a high-availability cluster.
proxy_txn_id	integer	Number of the transaction. These numbers are unique to the proxy distributor.
sequence_number	integer	The number of the operation.

Column	Type	Description
operation_type	char(10)	The type of operation to be performed; Insert, Update, Delete, or Other.
rowidn	integer	The ID of the row on which to apply the operation.
table	char	The full table name, trimmed to fit a reasonable length. Format: *database*:*owner*.*tablename*
sqlerrno	integer	Error number of any SQL error (or 0 on success)

sysproxytxns table

The **sysproxytxns** table contains information about all of the current transactions that are running through each proxy distributor.

On the primary server, this table contains information about each of the proxy distributors in the high-availability cluster. On a secondary server, this table only contains information about the proxy distributors used to process updates to the secondary server.

The following table provides information about the columns in the **sysproxytxns** table:

Column	Type	Description
proxy_id	integer	ID of the proxy distributor. These IDs are unique within a high-availability cluster.
proxy_txn_id	integer	Number of the transaction. These numbers are unique to the proxy distributor.
reference_count	integer	Indicates the number of threads (for example, sqlexec, sync reply, recovery, and so on) that are using the information for this transaction. When the count becomes 0 this indicates the transaction processing is complete. (either successfully or unsuccessfully).
pending_ops	integer	On the primary server: the number of operations received from the secondary server that have not yet been processed. On the secondary server, the number of operations buffered on the secondary server that have not yet been sent to the primary server.
proxy_sid	integer	Proxy Session ID

sysptnhdr

The **sysptrhdr** table contains information about partition headers.

Column	Type	Description
partnum	integer	Partnum of the table
flags	integer	Partition flags
rowsize	integer	Row size (maximum for variable)
ncols	smallint	Number of VARCHAR or BLOB columns
nkeys	smallint	Number of indexes
nextns	smallint	Number of extents
pagesize	smallint	Page size
created	integer	Date created
serialv	integer	Current SERIAL value
fextsiz	integer	First extent size, in pages
nextsiz	integer	Next extent size, in pages
nptotal	integer	Number of pages allocated
npused	integer	Number of pages used
npdata	integer	Number of data pages
octptnm	integer	Optical BLOB partnum
lockid	integer	Table lock ID
nrows	bigint	Number of data rows
ninserts	bigint	Number of insert operations
nupdates	bigint	Number of update operations
ndeletes	bigint	Number of delete operations
cur_serial8	int8	Current SERIAL8 value
cur_bigserial	bigint	Current BIGSERIAL value

Column	Type	Description
dbsnum	integer	Number of partitions in the dbspace
pta_oldvers	smallint	In-place alter
pta_newvers	smallint	In-place alter
pta_bmpagenum	integer	In-place alter
pta_totpgs	integer	In-place alter
pta_opems_allocd	integer	In-place alter
pta_opems_filled	integer	In-place alter
glscollname	char(32)	In-place alter
flags2	integer	Partition flags2
sid	integer	Temporary table session ID

You can run the following query to see the number of allocated pages for temporary tables:

```
SELECT i.sid, hex(i.flags) flags, hex(i.partnum) partition,
   trim(n.dbsname) || ":" || trim(n.owner) || ":" || trim(n.tabname) table,
   i.nptotal allocated_pages
  FROM sysmaster:systabnames n, sysmaster:sysptnhdr i
 WHERE (sysmaster:bitval(i.flags, "0x0020") = 1)
   AND i.partnum = n.partnum
```

For example, the query can return information similar to the following output:

```
session with query "select * from customer into temp good "
sid               60
flags             0x00000861
partition         0x00100249
table             demo:informix:good
allocated_pages   8

session with temp table generated from query "select from <view>"
sid               64
flags             0x00008821
partition         0x00100249
table             demo:informix:_temptable
allocated_pages   8

temp table from sorting
sid               33
flags             0x000048A0
partition         0x00200004
table             SORTTEMP:informix:th_tmprun_0x4a1b2370
allocated_pages   128

temp table from hashing
sid               31
flags             0x000048A0
partition         0x00200003
table             HASHTEMP:informix:th_overflow_0xffffffffffffffff
allocated_pages   16
```

sysptprof table

The **sysptprof** table lists information about a tblspace. Tblspaces correspond to tables.

Profile information for a table is available only when a table is open. When the last user who has a table open closes it, the tblspace in shared memory is freed, and any profile statistics are lost.

The following table provides information about the columns in the **sysptprof** table:

Column	Type	Description
dbsname	char(128)	Database name
tabname	char(128)	Table name
partnum	integer	Partition (tblspace) number
lockreqs	integer	Number of lock requests
lockwts	integer	Number of lock waits
deadlks	integer	Number of deadlocks
lktouts	integer	Number of lock timeouts
isreads	integer	Number of isreads
iswrites	integer	Number of iswrites
isrewrites	integer	Number of isrewrites
isdeletes	integer	Number of isdeletes

Column	Type	Description
bufreads	integer	Number of buffer reads
bufwrites	integer	Number of buffer writes
seqscans	integer	Number of sequential scans
pagreads	integer	Number of page reads
pagwrites	integer	Number of page writes

sysrepevtreg table

Use the **sysrepevtreg** pseudo table to register for a pre-defined set of events from the Connection Manager.

The following table provides information about the columns in the **sysrepevtreg** table:

Table 1. **sysrepevtreg** table information

Column	Type	Description
evt_bitmap	integer	Event ID bitmap
evt_timeout	integer	Maximum time in seconds that the client can wait for event data. Valid timeout values are: • 0; no wait (default) • -1; wait forever • *n* (where *n* > 0) wait *n* seconds
evt_hwm	integer	Pending event list high-water mark
evt_info	char(256)	Event information (Not yet implemented)

sysrepstats table

Use the **sysrepstats** table to post events to Connection Manager.

The following table provides information about the columns in the **sysrepstats** table:

Table 1. **sysrepstats** table information

Column	Type	Description
repstats_type	integer	Event ID
repstats_subtype	integer	Sub event ID
repstats_time	integer	Time at which event was initiated
repstats_ver	integer	Version number of event data
repstats_desc	lvarchar	Event data

- User Interface for sysrepstats and sysrepevtreg Tables
  Client applications can post events to Connection Manager or to other clients by inserting event information into the **sysrepstats** pseudo table. Client applications can register events using the sysmaster pseudo table **sysrepevtreg**, and receive event data by issuing select or fetch statements against the **sysrepstats** pseudo table.

User Interface for sysrepstats and sysrepevtreg Tables

Client applications can post events to Connection Manager or to other clients by inserting event information into the **sysrepstats** pseudo table. Client applications can register events using the sysmaster pseudo table **sysrepevtreg**, and receive event data by issuing select or fetch statements against the **sysrepstats** pseudo table.

By posting events to the **sysrepstats**, you can issue control messages to Connection Manager without having to directly connect to Connection Manager itself.

When Connection Manager registers that it wishes to receive events, it passes a bitmap of the event types that it wants to receive. As events are received, they are posted to the thread that placed the request.

Event Classes

The following table lists each event class, its bit value, and a description of the event class.

Table 1. Event Classes

Event class name	Bit value	Description
REPEVT_CLUST_CHG	0x1	Event class for High-Availability cluster changes
REPEVT_CLUST_PERFSTAT	0x2	Event class for workload statistics for the server nodes in a High-Availability cluster
REPEVT_CLUST_LATSTAT	0x4	Event class for replication latency information for server nodes in a High-Availability cluster
REPEVT_CM_ADM	0x8	Connection Manager administration commands
REPEVT_SRV_ADM	0x10	Event class for server mode changes
REPEVT_ER_ADM	0x20	Event class for events related to Enterprise Replication (ER)
REPEVT_CLIENT	0x40	User-defined client event

Sub-events for the Event Class REPEVT_CLUST_CHG

The following table lists sub-events for the event class REPEVT_CLUST_CHG:

Table 2. Sub-events for the Event Class REPEVT_CLUST_CHG

Sub-event name	Value	Description	Event available at:
REPEVT_SUB_CLUST_ADD	1	Adding new node to a High-Availability cluster	Only at primary server in a High-Availability cluster
REPEVT_SUB_CLUST_DROP	2	Dropping a node from a High-Availability cluster	Only at primary server in a High-Availability cluster
REPEVT_SUB_CLUST_CON	3	High-Availability secondary node connected to primary server	Only at primary server in a High-Availability cluster
REPEVT_SUB_CLUST_DIS	4	High-Availability secondary node disconnected from primary server	Only at primary server in a High-Availability cluster
REPEVT_SUB_CLUST_NEWPRIM	5	High-Availability primary node changed	Only at secondary servers in a High-Availability cluster
REPEVT_SUB_CLUST_DROFF	6	HDR secondary node disconnected from primary server	HDR primary and secondary servers
REPEVT_SUB_CLUST_DRON	7	HDR secondary node connected to primary server	HDR primary and secondary servers

Sub-events for the Event Class REPEVT_CLUST_PERFSTAT

The following table lists sub-events for the event class REPEVT_CLUST_PERFSTAT:

Table 3. Sub-events for the Event Class REPEVT_CLUST_PERFSTAT

Sub-event name	Value	Description	Event available at:
REPEVT_ SUB_LOCAL_PERFSTAT	1	Work load statistics for local server	All servers in a High-Availability cluster
REPEVT_ SUB_REMOTE_PERFSTAT	2	Work load statistics for High-Availability secondary servers	Only at the primary server in a High-Availability cluster

Sub-events for the Event Class REPEVT_CLUST_LATSTAT

The following table lists sub-events for the event class REPEVT_CLUST_LATSTAT:

Table 4. Sub-events for the Event Class REPEVT_CLUST_LATSTAT

Sub-event name	Value	Description	Event available at:
REPEVT_SUB_LOCAL_LATSTAT	1	Replication latency statistics for secondary servers in a High-Availability cluster	Only at the primary server in a High-Availability cluster

Sub-events for the Event Class REPEVT_CM_ADM

The following table lists sub-events for the event class REPEVT_CM_ADM:

Table 5. Sub-events for the Event Class REPEVT_CM_ADM

Sub-event name	Value	Description	Event available at:
REPEVT_SUB_CM_ADM_REQ	1	Command request	All server instances
REPEVT_SUB_CM_ADM_ACK	2	Command response	All server instances
REPEVT_SUB_CM_REG	3	Connection Manager registered with server	All server instances
REPEVT_SUB_CM_DEREG	4	Connection Manager de-registered with server	All server instances
REPEVT_SUB_CM_FATAL	5	Connection Manager terminated without de-registering with server	All server instances

Sub-events for the Event Class REPEVT_SRV_ADM

The following table lists sub-events for the event class REPEVT_SRV_ADM:

Table 6. Sub-events for the Event Class REPEVT_SRV_ADM

Sub-event name	Value	Description	Event available at:
REPEVT_ SUB_SRV_BLK	1	Server blocked due to DDRBLOCK	All server instances
REPEVT_ SUB_SRV_UBLK	2	Server unblocked; DDRBLOCK removed	All server instances

Sub-events for the Event Class REPEVT_ER_ADM

The following table lists sub-events for the event class REPEVT_ER_ADM:

Table 7. Sub-events for the Event Class REPEVT_ER_ADM

Sub-event name	Value	Description	Event available at:
REPEVT_SUB_ER_SPOOL_FULL	1	ER blocked while waiting for space to be added in either the queue data sbspace or dbspace, or in the grouper paging sbspace.	Enterprise Replication server nodes

sysrsslog

The **sysrsslog** table captures information about RS secondary servers at the primary server.

Table 1. **sysrsslog** table information

Column	Type	Description
server_name	char(128)	Server name
from_cache	integer	Total pages read from log buffer cache
from_disk	integer	Total pages read from disk
logpages_tossed	integer	Total number of log pages not written to log buffer cache

sysscblst

These columns of the **sysscblst** table provide information about session memory amounts.

Column	Type	Description
memtotal	integer	Total memory available
memused	integer	Total memory used

syssscelem

The **syssscelem** table provides information about Statement Cache Entries.

Column	Type	Description
uniqid	integer	Unique id of element
lru	integer	Index of lru queue
hash	integer	Hash value of cached entry
ref_cnt	integer	Num threads referencing the statement
hits	integer	Num times element used
flag	integer	• Invalid 0x1 • Fully Cached 0x2 • Inserting 0x4
valid	integer	Valid 1, Invalid 0
locked	integer	Locked 1, Unlocked 0
heap_ptr	bigint	Address of memory heap for cache entry
database	char(128)	Database name

Column	Type	Description
user	char(32)	User
stmtstring	char(16000)	Statement string
queryplan	char(16000)	Query plan

syssesappinfo

The **syssesappinfo** table in the **sysmaster** displays information on Distributed Relational Database Architecture™ (DRDA) client sessions. The **syssesappinfo** table has the following columns.

Table 1. **syssesappinfo** table column information

Column	Type	Explanation
sesapp_sid	INTEGER	Client session ID
sesapp_name	CHAR(128)	Session application name
sesapp_value	CHAR(512)	Session value

syssesprof

The **syssesprof** table lists cumulative counts of the number of occurrences of user actions such as writes, deletes, or commits.

Column	Type	Description
sid	integer	Session ID
lockreqs	integer	Number of locks requested
locksheld	integer	Number of locks currently held
lockwts	integer	Number of times waited for a lock
deadlks	integer	Number of deadlocks detected
lktouts	smallint	Number of deadlock time-outs
logrecs	integer	Number of logical-log records written
isreads	integer	Number of reads
iswrites	integer	Number of writes
isrewrites	integer	Number of rewrites
isdeletes	integer	Number of deletes
iscommits	integer	Number of commits
isrollbacks	integer	Number of rollbacks
longtxs	integer	Number of long transactions
bufreads	integer	Number of buffer reads
bufwrites	integer	Number of buffer writes
seqscans	integer	Number of sequential scans
pagreads	integer	Number of page reads
pagwrites	integer	Number of page writes
total_sorts	integer	Number of total sorts
dsksorts	integer	Number of sorts that did not fit in memory
max_sortdiskspace	integer	Maximum space used by a sort
logspused	integer	Number of bytes of logical-log space used by current transaction of session
maxlogsp	integer	Maximum number of bytes of logical-log usage for any single transaction since the session started

syssessions

The **syssessions** table provides general information on each user connected to the database server. In the **state** column, each bit position represents a separate flag. Thus, it might be easier to read values in the **state** column if the values are returned using the HEX function.

Table 1. **syssessions** table information

Column	Type	Description		
sid	integer	Session ID		
username	char(32)	User ID		
uid	smallint	User ID number		
pid	integer	Process ID of the client		
hostname	char(256)	Hostname of client		
tty	char(16)	Name of the user's **stderr** file		
connected	integer	Time that user connected to the database server		
feprogram	char(255)			
pooladdr	integer	Session pool address		
is_wlatch	integer	1 if the primary thread for the session is waiting for a latch		
is_wlock	integer	1 if the primary thread for the session is waiting for a lock		
is_wbuff	integer	1 if the primary thread for the session is waiting for a buffer		
is_wckpt	integer	1 if the primary thread for the session is waiting for a checkpoint		
is_wlogbuf	integer	1 if the primary thread for the session is waiting for a log buffer		
is_wtrans	integer	1 if the primary thread for the session is waiting for a transaction		
is_monitor	integer	1 if the session is a special monitoring process		
is_incrit	integer	1 if the primary thread for the session is in a critical section		
state	integer	Flags	Hexadecimal	Meaning
		1	0x00000001	User structure in use
		2	0x00000002	Waiting for a latch
		4	0x00000004	Waiting for a lock
		8	0x00000008	Waiting for a buffer
		16	0x00000010	Waiting for a checkpoint
		32	0x00000020	In a read call
		64	0x00000040	Writing logical-log file to backup tape
		256	0x00000100	In a critical section
		512	0x00000200	Special daemon
		1024	0x00000400	Archiving
		2048	0x00000800	Clean up dead processes
		4096	0x00001000	Waiting for write of log buffer
		8192	0x00002000	Special buffer-flushing thread
		16384	0x00004000	Remote database server
		32768	0x00008000	Deadlock timeout used to set RS_timeout
		65536	0x00010000	Regular lock timeout
		262144	0x00040000	Waiting for a transaction
		524288	0x00080000	Primary thread for a session
		1048576	0x00100000	Thread for building indexes
		2097152	0x00200000	B-tree cleaner thread

syssessiontempspaceusage

The **syssessiontempspaceusage** table contains information about each session's temp space usage, includes both implicit and explicit temp tables.

Column	Type	Description
sid	integer	ID of the session which allocated temp space
flags	char(10)	Partition flags of the temp space partition
partition	char(10)	Partition number of the temp space partition
table	lvarchar(290)	Table name of the temp space partition

Column	Type	Description
allocated_pages	integer	Number of pages allocated by the temp space partition

Example:

```
select * from syssessiontempspaceusage

sid               53
flags             0x00000861
partition         0x001001A4
table             stores_demo:jmcmahon:foo
allocated_pages   8
```

syssmx

The **syssmx** table provides SMX (server multiplexer group) connection information.

Table 1. **syssmx** table column information

Column	Type	Description
address	int8	SMX pipe address
name	char(128)	Target server name
encryption_status	char(20)	Enabled or disabled
buffers_sent	integer	Number of buffers sent
buffers_recv	integer	Number of buffers received
bytes_sent	int8	Number of bytes sent
bytes_recv	int8	Number of bytes received
reads	integer	Number of read calls
writes	integer	Number of write calls
retries	integer	Number of write call retries

syssmxses

The **syssmxses** table provides SMX (server multiplexer group) session information.

Table 1. **syssmxses** table column information

Column	Type	Description
name	char(128)	Target server name
address	int8	SMX session address
client_type	char(20)	SMX client type
reads	integer	Number of read calls
writes	integer	Number of write calls

syssqexplain table

The **syssqexplain** pseudo table stores information about SQL queries.

The information stored includes the plan of the query optimizer, an estimate of the number of rows returned, and the relative cost of the query.

Table 1. The syssqexplain pseudo table

Column	Type	Description
sqx_sessionid	INTEGER	The session ID associated with the SQL statement.
sqx_sdbno	INTEGER	The position of the query in the array of session IDs.
sqx_iscurrent	CHAR	Whether the query is the current SQL statement.
sqx_executions	INTEGER	The total number of executions of the query.
sqx_cumtime	FLOAT	The cumulative time to run the query. Important: If SQL tracing is disabled a zero is shown.

Column	Type	Description
sqx_bufreads	INTEGER	The number of buffer reads performed while running the query. Important: If SQL tracing is disabled a zero is shown.
sqx_pagereads	INTEGER	The number of page reads performed while running the query. Important: If SQL tracing is disabled a zero is shown.
sqx_bufwrites	INTEGER	The number of buffer writes performed while running the query. Important: If SQL tracing is disabled a zero is shown.
sqx_pagewrites	INTEGER	The number of page writes performed while running the query. Important: If SQL tracing is disabled a zero is shown.
sqx_totsorts	INTEGER	The total number of sorts performed while running the query. Important: If SQL tracing is disabled a zero is shown.
sqx_dsksorts	INTEGER	The number of disk sorts performed while running the query. Important: If SQL tracing is disabled a zero is shown.
sqx_sortspmax	INTEGER	The maximum disk space required by a sort.
sqx_conbno	SMALLINT	The position in the conblock list.
sqx_ismain	CHAR	Whether the query is in the main block for the statement.
sqx_selflag	VARCHAR(200,0)	The type of SQL statement, for example: SELECT, UPDATE, DELETE.
sqx_estcost	INTEGER	The estimated cost of the query.
sqx_estrows	INTEGER	The estimated number of rows returned by the query.
sqx_seqscan	SMALLINT	The number of sequential scans used by the query.
sqx_srtscan	SMALLINT	The number of sort scans used by the query.
sqx_autoindex	SMALLINT	The number of autoindex scans used by the query.
sqx_index	SMALLINT	The number of index paths used by the query.
sqx_remsql	SMALLINT	The number of remote paths used by the query.
sqx_mrgjoin	SMALLINT	The number of sort-merge joins used by the query.
sqx_dynhashjoin	SMALLINT	The number of dynamic hash joins used by the query.
sqx_keyonly	SMALLINT	The number of key-only scans used by the query.
sqx_tempfile	SMALLINT	The number of temporary files used by the query.
sqx_tempview	SMALLINT	The number of temporary tables for views created by the query.
sqx_secthreads	SMALLINT	The number of secondary threads used by the query.
sqx_sqlstatement	CHAR	The SQL query that was run.

syssqltrace

The **syssqltrace** table provides detailed information about a single SQL statement.

Column	Type	Description
sql_id	int8	Unique SQL execution ID
sql_address	int8	Address of the statement in the code block
sql_sid	int	Database session ID of the user running the SQL statement
sql_uid	int	User ID of the statement running the SQL
sql_stmttype	int	Statement type
sql_stmtname	char(40)	Statement type displayed as a word
sql_finishtime	int	Time this statement completed (UNIX)
sql_begintxtime	int	Time this transaction started
sql_runtime	float	Statement execution time
sql_pgreads	int	Number of disk reads for this SQL statement
sql_bfreads	int	Number of buffer reads for this SQL statement
sql_rdcache	float	Percentage of time the page was read from the buffer pool
sql_bfidxreads	int	Number of index page buffer reads
sql_pgwrites	int	Number of pages written to disk
sql_bfwrites	int	Number of pages modified and returned to the buffer pool
sql_wrcache	float	Percentage of time a page was written to the buffer pool but not to disk

Column	Type	Description
sql_lockreq	int	Total number of locks required by this SQL statement
sql_lockwaits	int	Number of times the SQL statement waited on locks
sql_lockwttime	float	Time the system waited for locks during SQL statement
sql_logspace	int	Amount of space the SQL statement used in the logical log
sql_sorttotal	int	Number of sorts that ran for the statement
sql_sortdisk	int	Number of sorts that ran on disk
sql_sortmem	int	Number of sorts that ran in memory
sql_executions	int	Number of times the SQL statement ran
sql_totaltime	float	Total amount of time spent running the statement
sql_avgtime	float	Average amount of time spent running the statement
sql_maxtime	float	Maximum amount of time spent executing the SQL statement
sql_numiowaits	int	Number of times an I/O operation had to wait
sql_avgiowaits	float	Average amount of time that the SQL statement had to wait
sql_totaliowaits	float	Total amount of time that the SQL statement had to wait for I/O. This excludes any asynchronous I/O.
sql_rowspersec	float	Average number of rows (per second) produced
sql_estcost	int	Cost associated with the SQL statement
sql_estrows	int	Estimated number of rows returned for the SQL statement as predicted by the optimizer
sql_actualrows	int	Number of rows returned for the SQL statement
sql_sqlerror	int	SQL error number
sql_isamerror	int	RSAM/ISAM error number
sql_isollevel	int	Isolation level of the SQL statement.
sql_sqlmemory	int	Number of bytes needed to execute the SQL statement
sql_numiterators	int	Number of iterators used by the statement
sql_database	char(128)	Database name
sql_numtables	int	Number of tables used in executing the SQL statement
sql_tablelist	char(4096)	List of table names directly referenced in the SQL statement. If the SQL statement fires triggers that execute statements against other tables, the other tables are not listed.
sql_statement	char(1600)	SQL statement that ran

syssqltrace_hvar

The **syssqltrace_hvar** table describes information about the SQL tracing host variable.

Column	Type	Description
sql_id	int8	SQL execution ID
sql_address	int8	Address of the SQL statement block
sql_hvar_id	int	ID of the SQL host variable
sql_hvar_flags	int	Flags for the host variable
sql_hvar_typeid	int	Type ID of the host variable
sql_hvar_xtypeid	int	xtype ID of the host variable
sql_hvar_ind	int	Index of the host variable
sql_hvar_type	char(128)	Type of host variable
sql_hvar_data	char(8192)	Value of host variable

syssqltrace_info

The **syssqltrace_info** table describes information about the SQL profile trace system.

Column	Type	Description
flags	integer	SQL trace flags

Column	Type	Description
ntraces	integer	Number of items to trace
tracesize	integer	Size of the text to store for each SQL trace item
duration	integer	Trace buffer (in seconds)
sqlseen	int8	Number of SQL items traced since start or resizing
starttime	integer	Time tracing was enabled
memoryused	int8	Number of bytes of memory used by SQL tracing

syssqltrace_iter

The **syssqltrace_iter** table lists the SQL statement iterators.

Column	Type	Description
sql_id	int8	SQL execution ID
sql_address	int8	Address of the SQL statement block
sql_itr_address	int8	Address of the iterator
sql_itr_id	int	Iterator ID
sql_itr_left	int	Iterator ID to the left
sql_itr_right	int	Iterator ID to the right
sql_itr_cost	int	Iterator cost
sql_itr_estrows	int	Iterator estimated rows
sql_itr_numrows	int	Iterator actual rows processed
sql_itr_type	int	Iterator type
sql_itr_misc	int	Iterator miscellaneous flags
sql_it_info	char(256)	Iterator miscellaneous flags displayed as text

syssrcrss

The **syssrcrss** table provides RS secondary server related statistics at the primary server.

Table 1. **syssrcrss** table column information

Column	Type	Description
address	int8	RS secondary server control block address
server_name	char(128)	Database server name
server_status	char(20)	Quiescent, active, or inactive
connection_status	char(20)	Connected or disconnected
log_transmission_status	char(20)	Active or blocked
next_page_tosend_log_uniq	integer	Unique log ID of next page to send
next_page_tosend_log_page	integer	Page number of next page to send
seq_tosend	integer	Sequence ID of last buffer sent
last_seq_acked	integer	Sequence ID of last buffer acknowledged

syssrcsds

The **syssrcsds** table provides SD secondary server related statistics at the primary server.

The **syssrcsds** table contains the columns that are shown in the following table.

Column	Type	Description
address	int8	SD secondary server control block address
source_server	char(128)	Primary database server name

Column	Type	Description
connection_status	char(20)	Connected or disconnected
last_received_log_uniq	integer	Unique log ID of last log page received
last_received_log_page	integer	Page number of last log page received
next_lpgtoread_log_uniq	integer	Unique log ID of next log page to read
next_lpgtoread_log_page	integer	Page number of next log page to read
last_acked_lsn_uniq	integer	Unique log ID of last LSN acknowledged
last_acked_lsn_pos	integer	Log position of last LSN acknowledged
last_seq_received	integer	Sequence ID of last buffer received
last_seq_acked	integer	Sequence ID of last buffer acknowledged
cur_pagingfile	char(640)	Current® paging file name
cur_pagingfile_size	int8	Current paging file size
old_pagingfile	char(640)	Old paging file name
old_pagingfile_size	int8	Old paging file size

systabnames

The **systabnames** table describes each table that the database server manages.

Column	Type	Description
partnum	integer	tblspace identifier
dbsname	char(128)	Database name
owner	char(32)	User ID of owner
tabname	char(128)	Table name
collate	char(32)	Collation associated with a database that supports GLS

systhreads

The **systhreads** table provides information about each thread.

Column	Type	Description
th_id	INTEGER	The numeric identifier of the thread.
th_addr	INTEGER	The memory address of the thread control block.
th_joinlist	INTEGER	If a list of the threads are waiting for this thread to exit, the th_joinlist column shows the address of the first thread in the list.
th_joinnext	INTEGER	If a list of the threads are waiting for this thread to exit, the th_joinnext column shows the address of the next thread in the join list.
th_joinee	INTEGER	The address of the thread whose exit this thread is waiting for.
th_name	CHAR(12)	The name of the thread.
th_state	INTEGER	The status code of the thread.
th_priority	INTEGER	The priority of the thread.
th_class	INTEGER	The code for the class of virtual processor that thread will run on.
th_vpid	INTEGER	The ID of the virtual processor that the thread was last scheduled to run on.
th_mtxwait	INTEGER	The address of the mutex that this thread is waiting for.
th_conwait	INTEGER	The address of the condition that this thread is waiting for.
th_waketime	INTEGER	The time of the expiration of the last sleep. The time is calculated by an internal clock. A value of -1 means that the time value is indeterminate.
th_startwait	INTEGER	The time when the last wait began. The time is calculated by an internal clock.
th_startrun	INTEGER	The time when the last execution began. The time is calculated by an internal clock.

systrgrss

The **systrgrss** table provides RS secondary server related statistics at the RS secondary server.

Column	Type	Description
address	int8	RS secondary server control block address
source_server	char(128)	Source server serving the RS secondary server
connection_status	char(20)	Connected or disconnected
last_received_log_uniq	integer	Unique log ID of last log page received
last_received_log_page	integer	Page number of last log page received
last_seq_received	integer	Sequence ID of last buffer received
last_seq_acked	integer	Sequence ID of last buffer acknowledged

systrgsds

The **systrgsds** table provides SD secondary server related statistics at the SD secondary server.

The **systrgsds** table contains these columns:

Column	Type	Description
address	int8	SD secondary server control block address
source_server	char(128)	Source server serving the SD secondary server
connection_status	char(20)	Connected or disconnected
last_received_log_uniq	integer	Unique log ID of last log page received
last_received_log_page	integer	Page number of last log page received
next_lptoread_log_uniq	integer	Unique log ID of next log page to read
next_lptoread_log_page	integer	Page number of next log page to read
last_acked_lsn_uniq	integer	Unique log ID of last LSN acknowledged
last_acked_lsn_pos	integer	Log position of last LSN acknowledged
last_seq_received	integer	Sequence ID of last buffer received
last_seq_acked	integer	Sequence ID of last buffer acknowledged
cur_pagingfile	char(640)	Current® paging file name
cur_pagingfile_size	int8	Current paging file size
old_pagingfile	char(640)	Old paging file name
old_pagingfile_size	int8	Old paging file size

sysvpprof

The **sysvpprof** table lists user and system CPU time for each virtual processor.

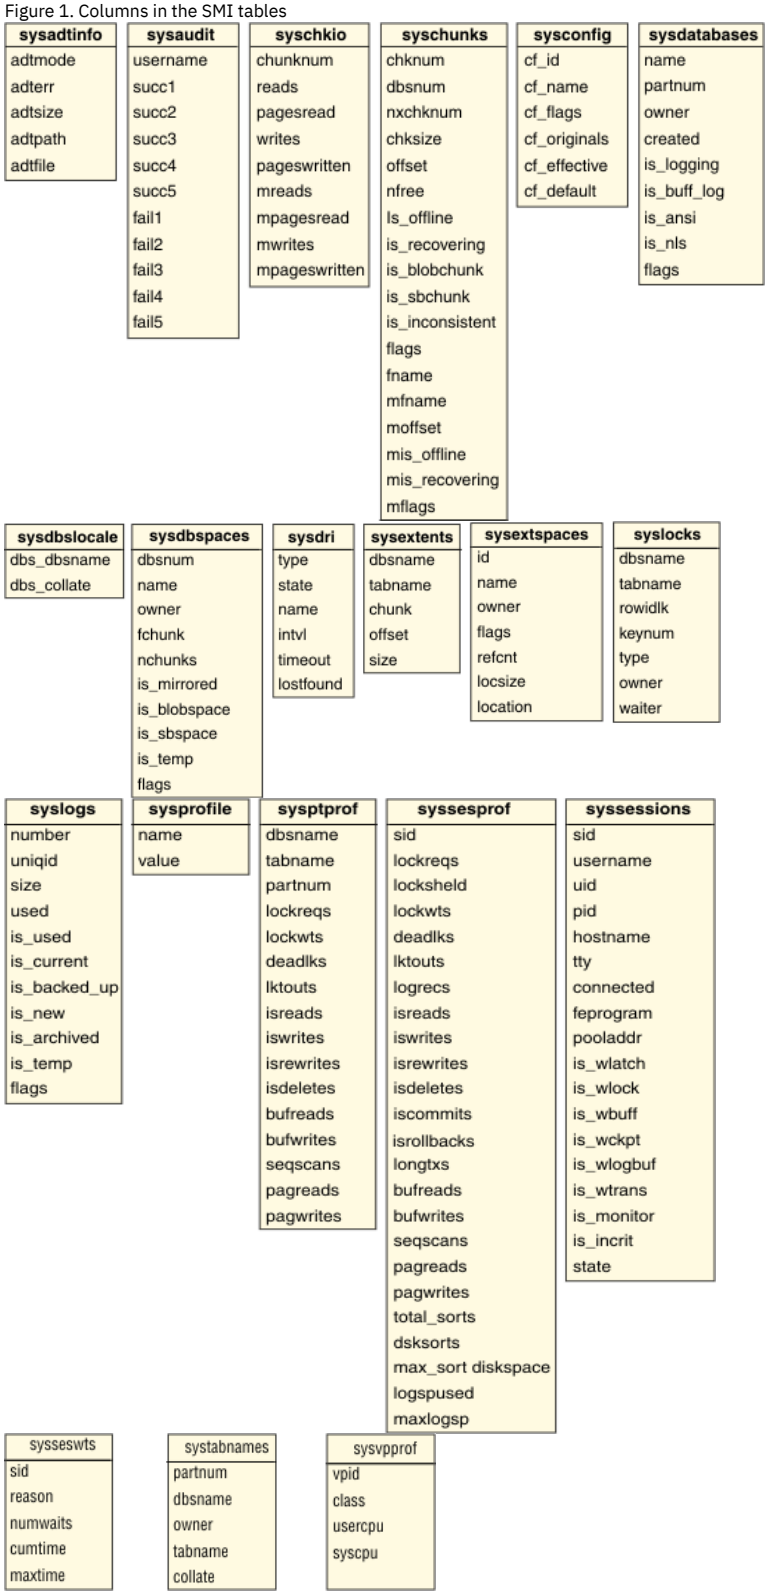
Column	Type	Description
vpid	integer	Virtual processor ID
	char(50)	Type of virtual processor: • cpu • adm • lio • pio • aio • tli • soc • str • shm • opt • msc • adt
usercpu	float	Number of microseconds of user time

Column	Type	Description
syscpu	float	Number of microseconds of system time

The SMI Tables Map

Figure 1 displays the columns in some of the SMI tables.

Figure 1. Columns in the SMI tables



Information from onstat in the SMI Tables

To obtain information provided by the **onstat** utility, you can use SQL to query appropriate SMI tables. The following table indicates which SMI tables to query to obtain the information provided by a given **onstat** option. For descriptions of the **onstat** options, see Monitor the database server status.

onstat Option	SMI Tables to Query	onstat Fields *Not* in SMI Tables
-d	sysdbspaces syschunks	address bpages
-D	sysdbspaces syschkio	
-F	sysprofile	address flusher snoozer state data
-g ath	systhreads	
-g dri	sysdri	Last DR CKPT (id/pg)
-g glo	sysvpprof	Listing of virtual processors by
-g ipl	sysipl	
-g rss	sysrsslog systrgrss syssrcrss	
-g his	syssqltracing	
-g sds	syssrcsds systrgsds	
-g smx	syssmx	
-g smx ses	syssmxses	
-k	syslocks	address lklist tblsnum
-l	syslogs sysprofile	All physical-log fields (except numpages and numwrits) All logical-log buffer fields (except numrecs, numpages, and numwrits) address begin % used
-p	sysprofile	
-u	syssessions syssesprof	address wait nreads nwrites

The sysadmin Database

The **sysadmin** database contains the tables that contain and organize the Scheduler tasks and sensors, store data collected by sensors, and record the results of Scheduler jobs and SQL administration API functions.

By default, only user **informix** is granted access to the **sysadmin** database; other users can be granted access to the **sysadmin** database.

Do not drop or alter the **sysadmin** database because it is used by several important database server components. You can, however, move the **sysadmin** database from its default root dbspace location if the root dbspace does not have enough space for storing task properties and command history information. To move the **sysadmin** database, use the SQL administration API **admin()** or **task()** function with the reset sysadmin argument.

Important: Moving the **sysadmin** database resets the database back to the original state when it was first created; all data, command history, and results tables are lost. Only built-in tasks, sensor, and thresholds remain in the **sysadmin** tables.

- The Scheduler tables
  The Scheduler stores information about tasks and sensors in five tables in the **sysadmin** database: **ph_task**, **ph_run**, **ph_group**, **ph_alert**, and **ph_threshold**.
- The results tables
  The results tables contain historical data about sensors that are run by the Scheduler.
- The command_history table
  The **command_history** table contains the list and results of all the SQL administration API functions that were run in the previous 30 days.
- The storagepool table
  The **storagepool** table in **sysadmin** database contains information about all of the entries in the storage pool in an Informix® instance. Each entry represents free space that the server can use when automatically expanding a storage space.
- The tenant table
  The **tenant** table in the **sysadmin** database contains information about the tenant databases.

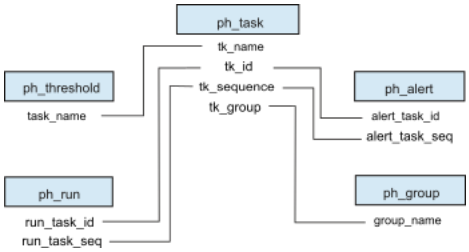
Related reference:
reset sysadmin argument: Move the sysadmin database (SQL administration API)

The Scheduler tables

The Scheduler stores information about tasks and sensors in five tables in the **sysadmin** database: **ph_task**, **ph_run**, **ph_group**, **ph_alert**, and **ph_threshold**.

The Scheduler is an administrative tool that enables the database server to execute database functions and procedures at predefined times or as determined internally by the server. The five tables used by the Scheduler contain built-in tasks and sensors that run automatically. You can also add your own tasks and sensors by inserting rows into these tables. These tables have relationships between their columns that are described in the following illustration.

Figure 1. Relationships between the Scheduler tables



For detailed information about using the Scheduler, see the *IBM® Informix® Administrator's Guide*.

- The ph_task Table
  The **ph_task** table contains information about Scheduler tasks and sensors. The **ph_task** table contains built-in tasks and sensors that are scheduled to run automatically.
- The ph_run Table
  The **ph_run** table contains information about how and when each Scheduler task or sensor ran.
- The ph_group Table
  The **ph_group** table contains information about the Scheduler group names. The **ph_group** table contains several groups that are used to categorize built-in tasks and sensors, as well as the default group MISC.
- The ph_alert Table
  The **ph_alert** table contains information about event alarms generated by the database server or alerts generated by the Scheduler. Alerts that are associated with built-in tasks and sensors are automatically added to the **ph_alert** table.
- The ph_threshold Table
  The **ph_threshold** table contains information about thresholds for Scheduler tasks.

Related information:
Scheduler tables

The ph_task Table

The **ph_task** table contains information about Scheduler tasks and sensors. The **ph_task** table contains built-in tasks and sensors that are scheduled to run automatically.

Table 1. The ph_task table

Column	Type	Description
tk_id	serial	Sequential job ID. System updated; do not modify. Referenced in the **alert_task_id** column in the **ph_alert** table and in the **run_task_id** column in the **ph_run** table.
tk_name	char(36)	Job name. A unique index on this column ensures that no two names are the same. Referenced in the **task_name** column of the **ph_threshold** table.
tk_description	lvarchar	Description about what the task or sensor does.
tk_type	char(18)	Type of job: • TASK: Invokes an action at a specific time and frequency • SENSOR: (Default) A task that collects, stores, and purges data to or from a result table • STARTUP TASK: A task that runs only when the server starts • STARTUP SENSOR: A sensor that runs only when the server starts
tk_sequence	integer	Current® data collection number. System updated; do not modify. Referenced in the **alert_task_id** column of the **ph_alert** table and the **run_task_seq** column of the **ph_run** table.
tk_result_table	varchar	Results table name for storing data collected by a sensor. The table is created by the CREATE TABLE statement in the **tk_create** column.
tk_create	lvarchar	The CREATE TABLE statement used to create the results table to store data collected by a sensor. One of the columns in the table must be named ID and hold the **tk_sequence** value. This value indicates the age of the row and can be used for purging the row.
tk_dbs	varchar(250)	The database in which the task is run. Default is `sysadmin`.
tk_execute	lvarchar	The SQL statement to execute. The length of the command is limited to 2048 bytes.
tk_delete	interval day(2) to second	Data older than this interval is deleted from the result table. Default is `1:00:00` (one day).
tk_start_time	datetime hour to second	Time when the task or sensor starts. Default is `08:00:00`.

Column	Type	Description
tk_stop_time	datetime hour to second	Time of day after which the task or sensor cannot be scheduled to be run. The database server schedules the next execution on the next valid day. Default is `19:00:00`. Can be `NULL`, indicating no stop time.
tk_frequency	interval day(2) to second	How often this task or sensor runs. Default is `1` (once a day).
tk_next_execution	datetime year to second	Next time this task or sensor will be run. After a startup task or sensor has run, this value is NULL. When a task or a sensor is enabled, the database server calculates this time from the values of **tk_start_time**, **tk_stop_time**, and **tk_frequency** columns, and the days of the week the task or sensor is enabled, according to the values of **tk_monday**, **tk_tuesday**, **tk_wednesday**, **tk_thursday**, **tk_friday**, **tk_saturday**, **tk_sunday** columns. For example, *`new_next_execution_time = current_next_execution_time + tk_frequency`*, where the *new_next_execution_time* is greater than the *current_next_execution_time*. If **tk_frequency** is not present, the task is run once.
tk_total_executions	integer	The number of times that the task or sensor was run. System updated; do not modify. Default is `0`.
tk_total_time	float	Total time spent executing this task or sensor. System updated; do not modify Default is `0.0` seconds.
tk_monday	boolean	Whether the task or sensor is run on Monday. Default is `T` (true).
tk_tuesday	boolean	Whether the task or sensor is run on Tuesday. Default is `T` (true).
tk_wednesday	boolean	Whether the task or sensor is run on Wednesday. Default is `T` (true).
tk_thursday	boolean	Whether the task or sensor is run on Thursday. Default is `T` (true).
tk_friday	boolean	Whether the task or sensor is run on Friday. Default is `T` (true).
tk_saturday	boolean	Whether the task or sensor is run on Saturday. Default is `T` (true).
tk_sunday	boolean	Whether the task or sensor is run on Sunday. Default is `T` (true).
tk_attributes	integer	Flags System updated; do not modify.
tk_group	varchar(128)	Group name. Must be the same as a value in the **group_name** column in the **ph_group** table. Default is `MISC`.
tk_enable	boolean	Whether the task or sensor is enabled. Default is `T` (the task is enabled).
tk_priority	integer	Job priority, on a scale of 0- 5, with higher numbers indicating higher priority. If there are several jobs to execute simultaneously, the job with the highest priority executes first. Default is `0` (low priority).

The ph_run Table

The **ph_run** table contains information about how and when each Scheduler task or sensor ran.

Table 1. The ph_run table

Column	Type	Description
run_id	serial	Sequential ID generated during execution. System updated; do not modify.
run_task_id	integer	The job ID. Referenced from the **tk_id** column of the **ph_task** table.
run_task_seq	integer	Unique sequence number of the task or sensor. Referenced from the **tk_sequence** column of the **ph_task** table.
run_retcode	integer	The return code from a stored procedure function or a user-defined routine, or the SQLCode from SQL statements.
run_time	datetime year to second	When this task or sensor was run.

Column	Type	Description
run_duration	float	The time that it took to run this task or sensor (in seconds).
run_ztime	integer	The time when the server statistics (the **onstat -z** command) were last run.
run_btime	integer	The time when the server was started.
run_mttime	integer	Internal counter of the server.

The ph_group Table

The **ph_group** table contains information about the Scheduler group names. The **ph_group** table contains several groups that are used to categorize built-in tasks and sensors, as well as the default group MISC.

Table 1. The ph_group table

Column	Type	Description
group_id	serial	Group ID. System updated; do not modify.
group_name	varchar(128)	Unique name of the group. Referenced in the **tk_group** column of the **ph_task** table.
group_description	lvarchar	Description of the group.

The ph_alert Table

The **ph_alert** table contains information about event alarms generated by the database server or alerts generated by the Scheduler. Alerts that are associated with built-in tasks and sensors are automatically added to the **ph_alert** table.

Table 1. The ph_alert table

Column	Type	Description
id	serial	The alert ID. System generated; do not modify.
alert_task_id	serial	The task or sensor ID. Must be the same as a value in the **tk_id** column in the **ph_task** table. The task ID for event alarms is 15.
alert_task_seq	integer	Identifies which invocation of a task created the alert. System generated; do not modify. Referenced from the **tk_sequence** column in the **ph_task** table.
alert_type	char(8)	The type of alert: • INFO (Default) • WARNING • ERROR The severity of an alert or event alarm is indicated by the combination of the alert type and the alert color. See Table 2.
alert_color	char(15)	The color of the alert: • GREEN (Default) • YELLOW • RED The severity of an alert or event alarm is indicated by the combination of the alert type and the alert color. See Table 2.
alert_time	datetime year to second	The time when the alert was generated. System updated; do not modify.

Column	Type	Description
alert_state	char(15)	Indicates which state the object is in: NEW (Default) The alert was added and no other action has occurred on this alert. IGNORED The alert was acknowledged by the DBA and no action was taken. ACKNOWLEDGED The alert was acknowledged by the DBA. ADDRESSED The alert was addressed by the DBA.
alert_state_changed	datetime year to second	The last time that the state was changed. System updated; do not modify.
alert_object_type	char(15)	The type of object that the alert is for: • ALARM • CHUNK • DATABASE • DBSPACE • INDEX • MISC (Default) • SERVER • SQL_STATEMENT • TABLE • USER
alert_object_name	varchar(255)	The name of the object that the alert is for or the event alarm class ID.
alert_message	lvarchar	The detailed message describing the alert or event alarm.
alert_action_dbs	lvarchar(256)	The name of the database to use for the corrective action. Default is **sysadmin**.
alert_action	lvarchar	The corrective action. An SQL script to invoke to correct the problem. This script must comply with all multi-statement prepare rules. Can be `NULL` if no action is available.
alert_object_info	bigint	For alerts of type ALARM, the event ID of the event alarm.

The following table defines the alert colors for the three types of messages and event alarms.

Table 2. Alert types and colors

Message Type	Green	Yellow	Red
Informative	A status message indicating a component's operation status. An event alarm of severity 1 (not noteworthy).	An important status message. An event alarm of severity 2 (information).	A status message that requires action.
Warning	A warning from the database that was automatically addressed.	A future event that needs to be addressed. An event alarm of severity 3 (attention).	A predicted failure is imminent. Immediate action is required.
Error	A failure in a component corrected itself.	A failure in a component corrected itself but might need DBA action.	A failure in a component requires DBA action. An event alarm of severity 4 (emergency) or 5 (fatal).

The **ph_alerts** view shows alert information and associated task or sensor information.

Related concepts:
Events in the ph_alert Table

The ph_threshold Table

The **ph_threshold** table contains information about thresholds for Scheduler tasks.

The **ph_threshold** table contains built-in thresholds that are associated with built-in tasks and sensors. For example, a threshold named COMMAND HISTORY RETENTION determines the length of time rows should remain in the **command_history** table.

Table 1. The ph_threshold table

Column	Type	Description
id	integer	Threshold ID.
name	char	The name of the threshold.

Column	Type	Description
task_name	varchar	Scheduler task name associated with the threshold. Must be the same as a value in the **tk_name** column in the **ph_task** table.
value	lvarchar	The value of the threshold.
value_type	char	The data type of the value column: • STRING • NUMERIC • NUMERIC(p,s)
description	lvarchar	A long description of the threshold.

The results tables

The results tables contain historical data about sensors that are run by the Scheduler.

Most sensors create a new table to store their results. The name of the table is listed in the **tk_result_table** column in the **ph_task** table. The structure of the table is defined by the CREATE TABLE statement in the **tk_create** column of the **ph_task** table.

The built-in sensors automatically create results tables when they run that start with the prefix **mon_**.

Table 1. Results tables

Column	Type	Description
ID	integer	The iteration sequence number of the sensor. Must be set to $DATA_SEQ_ID. Referenced from the **run_task_seq** column of the **ph_run** table.
user columns	any	You can specify any types of columns to hold the information returned by a sensor.

The command_history table

The **command_history** table contains the list and results of all the SQL administration API functions that were run in the previous 30 days.

The **command_history** table shows each SQL administration API function that was run and displays information about the user who ran the function, the time the function was run, the primary arguments of the function, and the message returned when the database server completed running the function.

Table 1. The command_history table

Column	Data Type	Description
cmd_number	serial	The unique ID for each row.
cmd_exec_time	datetime year-to-second	The time that the function started.
cmd_user	varchar	The user who ran the function.
cmd_hostname	varchar	The name of the host computer from which the function was run.
cmd_executed	varchar	The primary argument of the function that was run.
cmd_ret_status	integer	Return code.
cmd_ret_msg	lvarchar	Return message.

The following table shows sample arguments and the associated results messages in a **command_history** table.

Table 2. Example information in a command_history table

Argument (cmd_executed)	Message Returned (cmd_ret_msg)
set sql tracing on	SQL tracing on with 1000 buffers of 2024 bytes.
create dbspace	Space 'space12' added.
checkpoint	Checkpoint completed.
add log	Added 3 logical logs to dbspace logdbs.

To display the command history, run the following SQL statement from the **sysadmin** database:

```
SELECT * FROM command_history;
```

The size of the command_history table

Depending on how many SQL administration API functions are run, the **command_history** table can grow quite large. You can change the amount of time that information is retained in the **command_history** table by updating the **value** field of the COMMAND HISTORY RETENTION row in the **ph_threshold** table.

You can also use SQL statements like DELETE or TRUNCATE TABLE to manually remove the data from this table.

Related information:
Viewing SQL administration API history

The storagepool table

The **storagepool** table in **sysadmin** database contains information about all of the entries in the storage pool in an Informix® instance. Each entry represents free space that the server can use when automatically expanding a storage space.

Table 1. The **storagepool** table

Column	Type	Description
entry_id	SERIAL	The ID of the storage pool entry.
path	VARCHAR (255)	The path for the file, directory, or device that the server can use when additional storage space is required.
beg_offset	BIGINT	The initial offset in kilobytes into the device at which the server can begin allocating space. If the storage pool information is for a directory, the end offset value is `0`.
end_offset	BIGINT	The initial offset in kilobytes into the device at which the server must stop allocating space. If the storage pool information is for a directory, the offset value is `0`.
chunk_size	BIGINT	The initial size of a chunk allocated from this entry.
status	VARCHAR (255)	The status of the storage pool entry. Status values are: • Active = A functional storage pool entry. The server can allocate chunks from this entry. • Full = There is no more free space in the storage pool entry. The server cannot allocate any more chunks from this entry. • Error = The storage pool entry generated an error when the server tried to allocate a chunk from the entry.
priority	INT	The priority of the directory, file, or device when the server searches through the storage pool for space. The server allocates space from a high-priority entry before it allocates space from a lower priority entry. • 1 = High priority • 2 = Medium priority • 3 = Low priority
last_alloc	DATETIME (year to second)	The date and time of the last allocation from this entry.
logid	INT	The ID of the log that was current at the time this entry was last used. The server uses this flag with the `logused` value when choosing between entries of identical priorities.
logused	INT	The position within the log that was current at the time this entry was last used. The server uses this flag with the `logid` value when choosing between entries of identical priorities.

The tenant table

The **tenant** table in the **sysadmin** database contains information about the tenant databases.

Table 1. The **tenant** table

Column	Type	Description
tenant_id	int	The unique ID of the tenant database.
tenant_dbsname	varchar(128)	The name of the tenant database.
tenant_resources	bson	The properties of the tenant database and the state of the tenant. Cast this column to JSON to view the information.
tenant_last_updated	datetime year to second	The time stamp of the last configuration change to the tenant database.
tenant_comment	lvarchar(2048)	Comments about the tenant database.

Disk Structures and Storage

In This Chapter

The database server achieves its high performance by managing its own I/O. The database server manages storage, search, and retrieval. As the database server stores data, it creates the structures it needs to search for and retrieve the data later. The database server disk structures also store and track control information needed to manage logging and backups. Database server structures contain all the information needed to ensure data consistency, both physical and logical.

Before you read this chapter, familiarize yourself with the disk-space terms and definitions in the chapter on where data is stored in the *IBM® Informix® Administrator's Guide*.

This chapter discusses the following topics related to disk data structures:

- Dbspace structure and storage
- Storage of simple large objects
- Sbspace structure
- Time stamps
- Database and table creation: what happens on disk

- Dbspace Structure and Storage
- Storage of Simple Large Objects
- Sbspace Structure
  An sbspace is similar to a blobspace except that it holds smart large objects.
- Time Stamps
- Database and Table Creation: What Happens on Disk

Dbspace Structure and Storage

This section explores the disk structures and storage techniques that the database server uses to store data in a dbspace.

- Structure of the Root Dbspace
  As part of disk-space initialization, the database server initializes specific structures in the initial chunk of the root dbspace.
- Reserved Pages
- Structure of a Regular Dbspace
- Structure of the Chunk Free-List Page
- Structure of the Tblspace Tblspace
- Structure of the Database Tblspace
- Structure and Allocation of an Extent
- Structure and Storage of a Dbspace Page
- Structure of Fragmented Tables
- Structure of B-Tree Index Pages
- Structure of R-Tree Index Pages

Related information:
Forest of trees indexes

Structure of the Root Dbspace

As part of disk-space initialization, the database server initializes specific structures in the initial chunk of the root dbspace.

The following structures are initialized:

- Twelve reserved pages
- The first chunk free-list page
- The tblspace tblspace
- The physical log
- The logical-log files
- The database tblspace

The ROOTNAME, ROOTOFFSET, ROOTPATH, and ROOTSIZE configuration parameters specify the size and location of the initial chunk of the root dbspace. If the root dbspace is mirrored, the MIRROROFFSET and MIRRORPATH configuration parameters specify the mirror-chunk location. For more information about these parameters, see Database configuration parameters.

To see the structure of the root chunk use the **oncheck -pe** command. For more information, see oncheck -ce, -pe: Check the chunk-free list.

Reserved Pages

The first 12 pages of the initial chunk of the root dbspace are reserved pages. Each reserved page contains specific control and tracking information used by the database server.

To obtain a listing of the contents of your reserved pages, execute the command **oncheck -pr**. To also list information about the physical-log and logical-log pages, including the active physical-log pages, run the **oncheck -pR** command.

The following example shows sample **oncheck -pr** output for interval checkpoints:

```
        Time of checkpoint      10/25/2005 17:05:20
        Checkpoint Interval               1234
```

The database server also stores current configuration information in a reserved page called PAGE_CONFIG. If you change the configuration parameters from the command line and run the **oncheck -pr** command without shutting down and restarting the database server, the configuration values in the command output do not match the current values in the reserved pages. The **oncheck** utility returns a warning message.

The following example shows sample output of the contents of a PAGE_CONFIG reserved page.

```
...

Validating Informix database server reserved pages - PAGE_CONFIG
    ROOTNAME                        rootdbs
    ROOTPATH                        /home/dyn_srv/root_chunk
    ROOTOFFSET                      4
    ROOTSIZE                        8000
    MIRROR                          0
    MIRRORPATH
    MIRROROFFSET                    0
    PHYSFILE                        1000
    LOGFILES                        5
    LOGSIZE                         500
    MSGPATH                         /home/dyn_srv/online.log
    CONSOLE                             /dev/ttyp5
...                                 ...
```

oncheck -pr and pR: Display reserved-page information

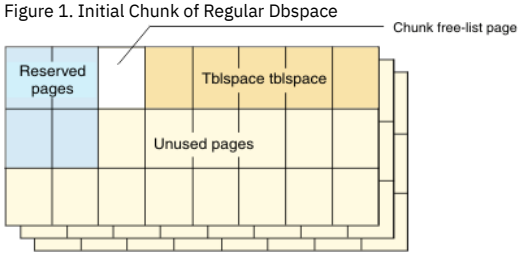
Structure of a Regular Dbspace

After disk-space initialization, you can add new dbspaces. When you create a dbspace, you assign at least one chunk (either raw or cooked disk space) to the dbspace. This chunk is referred to as the initial chunk of the dbspace. Figure 1 illustrates the structure of the initial chunk of a regular (nonroot) dbspace.

When the dbspace is first created, it contains the following structures:

- Two reserved pages
- The first chunk free-list page in the chunk
- The tblspace **tblspace** for this dbspace
- Unused pages

Figure 1. Initial Chunk of Regular Dbspace



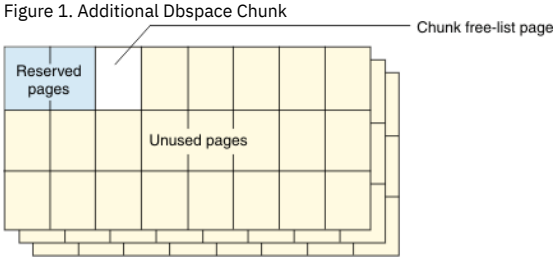
- Structure of an Additional Dbspace Chunk
- Structure of a Mirror Chunk

Structure of an Additional Dbspace Chunk

You can create a dbspace that contains more than one chunk. The initial chunk in a dbspace contains the tblspace **tblspace** for the dbspace. Additional chunks do not. When an additional chunk is first created, it contains the following structures:

- Two reserved pages
- The first chunk free-list page
- Unused pages

Figure 1 illustrates the structure of all additional chunks in a dbspace. (The structure also applies to additional chunks in the root dbspace.)
Figure 1. Additional Dbspace Chunk

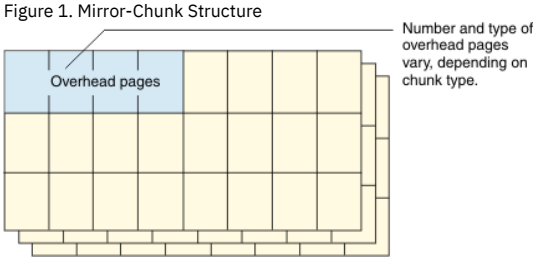


Structure of a Mirror Chunk

Each mirror chunk must be the same size as its primary chunk. When a mirror chunk is created, the database server writes the contents of the primary chunk to the mirror chunk immediately.

The mirror chunk contains the same control structures as the primary chunk. Mirrors of blobspace, sbspace, or dbspace chunks contain the same physical contents as their primary counterpart after the database server brings them online.

Figure 1 illustrates the mirror-chunk structure as it appears after the chunk is created.
Figure 1. Mirror-Chunk Structure



The mirror-chunk structure always shows no free space because all of its space is reserved for mirroring. For more information, see the chapter on what is mirroring in the *IBM® Informix® Administrator's Guide*.

Structure of the Chunk Free-List Page

In every chunk, the page that follows the last reserved page is the first of one or more chunk free-list pages that tracks available space in the chunk. For a non-root chunk, the initial length of the free space is equal to the size of the chunk minus three pages. If an additional chunk free-list page is needed to accommodate new entries, a new chunk free-list page is created in one of the free pages in the chunk. Figure 1 illustrates the location of the free-list page.

Use **oncheck -pe** to obtain the physical layout of pages in the chunk. For more information, see oncheck -ce, -pe: Check the chunk-free list.
Figure 1. Free-List Page

Structure of the Tblspace Tblspace

Each dbspace contains a tblspace called the *tblspace* ***tblspace*** that describes all tblspaces in the dbspace. When the database server creates a tblspace, it places an entry in the tblspace **tblspace** that describes the characteristics of the newly created tblspace. You cannot drop or move a chunk containing a tblspace **tblspace.**

A dbspace can have a maximum number of 2**20 tblspaces.

The default size of the first and next extents depends on whether the dbspace is the root dbspace or not, as shown in the following table.

Table 1. Default sizes for each extent and type of dbspace

Type of dbspace	Default Size of First Extent	Default Size of Next Extents
Root	• 500 KB for a 2 kilobyte page system • 1000 KB for a 4 kilobyte page system	• 100 KB for a 2 kilobyte page system • 200 KB for a 4 kilobyte page system
Non-root	• 100 KB for a 2 kilobyte page system • 200 KB for a 4 kilobyte page system	• 100 KB for a 2 kilobyte page system • 200 KB for a 4 kilobyte page system

You can specify a non-default size for the first and next extents for a tblspace **tblspace** in the following ways:

- For the root dbspace, set the TBLTBLFIRST and TBLTBLNEXT configuration parameters.
- For non-root dbspaces, use the **onspaces** utility **-ef** and **-en** options when you create a dbspace.

Tblspace tblspace entries

The tblspace **tblspace** describes the characteristics of tblspaces.

To display information on a tblspace, use the **oncheck -pt** command.

Table 1. tblspace tblspace entries

Component	Description
Page header	24 bytes, standard page-header information
Page-ending time stamp	4 bytes
Tblspace header	136 bytes, general tblspace information
Tblspace name	*database.owner.tablename* or *database.owner.indexname* Typically 30-40 bytes long but can be longer, depending on the length of the name.
Column information	8 bytes for each special column A special column is defined as a VARCHAR, BYTE, TEXT, or user-defined data type.
Index information	For attached indexes, each index in the partition has a 20-byte header that contains general information about the index, followed by a 4-byte entry for each column in the index. For detached indexes, a 4-byte entry for each column in the index.
Extent information	A 10-byte entry plus 10 bytes of information for each extent that is allocated to the tblspace. During the defragmentation of the tblspace, more bytes might be used.

Related reference:
oncheck -pt and -pT: Display tblspaces for a Table or Fragment

Tblspace Numbers

Each tblspace that is described in the tblspace tblspace receives a tblspace number. This tblspace number is the same value that is stored as the **partnum** field in the **systables** system catalog table and as the **partn** field in the **sysfragments** system catalog table.

The following SQL query retrieves the **partnum** for every table in the database (these can be located in several different dbspaces) and displays it with the table name and the hexadecimal representation of **partnum**:

```
SELECT tabname, tabid, partnum, HEX(partnum) hex_tblspace_name FROM systables
```

If the output includes a row with a table name but a **partnum** of 0, this table consists of two or more table fragments, each located in its own tblspace. For example, Figure 1 shows a table called **account** that has **partnum** 0.

Figure 1. Output from systables Query with partnum Values

```
tabname         tabid   partnum          hex_tblspace_name

sysfragments     25     1048611          0x00100023
branch          100     1048612          0x00100024
teller          101     1048613          0x00100025
account         102           0          0x00000000
history         103     1048615          0x00100027
results         104     1048616          0x00100028
```

To obtain the actual tblspace numbers for the fragments that make up the table, you must query the **sysfragments** table for the same database. Figure 2 shows that the **account** table from Figure 1 has three table fragments and three index fragments.

Figure 2. Output from sysfragments Table with partn Values

```
tabid  fragtype     partn          hex_tblspace_name

  102  T            1048614        0x00100026
  102  T            2097154        0x00200002
  102  T            3145730        0x00300002
  102  I            1048617        0x00100029
  102  I            2097155        0x00200003
  102  I            3145731        0x00300003
```

Tblspace Number Elements

The first page in a tblspace is logical page 0. (Physical page numbers refer to the address of the page in the chunk.) The root space tblspace **tblspace** is always contained in the first dbspace and on logical page 1 within the tblspace **tblspace**. (The bitmap page is page 0.)

Tblspace Tblspace Size

These tblspace **tblspace** pages are allocated as an extent when the dbspace is initialized. If the database server attempts to create a table, but the tblspace **tblspace** is full, the database server allocates a next extent to the tblspace.

When a table is removed from the dbspace, its corresponding entry in the tblspace **tblspace** is deleted.

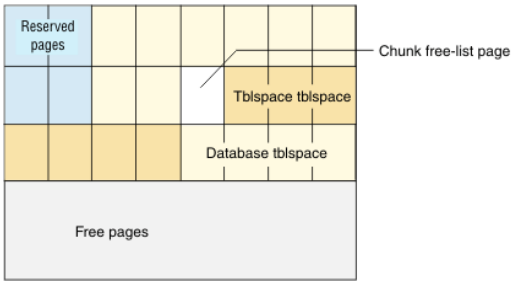
Tblspace Tblspace Bitmap Page

The first page of the tblspace **tblspace**, like the first page of any initial extent, is a bitmap that describes the page fullness of the following pages. Each page that follows has an entry on the bitmap page. If needed, additional bitmap pages are located throughout the contiguous space allocated for the tblspace, arranged so that each bitmap describes only the pages that follow it, until the next bitmap or the end of the dbspace. Bitmap pages fall at distinct intervals within tblspaces pages. Each bitmap page describes a fixed number of pages that follow it.

Structure of the Database Tblspace

The database tblspace appears only in the initial chunk of the root dbspace. The database tblspace contains one entry for each database managed by the database server. Figure 1 illustrates the location of the database tblspace.

Figure 1. Database Tblspace Location in Initial Chunk of Root Dbspace



Database Tblspace Number

The tblspace number of the database tblspace is always 0x100002. This tblspace number appears in an **onstat -t** listing if the database tblspace is active.

- Database Tblspace Entries

Database Tblspace Entries

Each database tblspace entry includes the following five components:

- Database name
- Database owner
- Date and time that the database was created
- The tblspace number of the **systables** system catalog table for this database
- Flags that indicate logging mode

The database tblspace includes a unique index on the database name to ensure that every database is uniquely named. For any database, the **systables** table describes each permanent table in the database. Therefore, the database tblspace only points to the detailed database information located elsewhere.

When the root dbspace is initialized, the database tblspace first extent is allocated. The initial-extent size and the next-extent size for the database tblspace are four pages. You cannot modify these values.

Structure and Allocation of an Extent

This section covers the following topics:

- Extent structure
- Next-extent allocation

- Extent Structure
- Next-Extent Allocation

Extent Structure

An extent is a collection of contiguous pages within a dbspace. Every permanent database table has two extent sizes associated with it. The initial-extent size is the number of kilobytes allocated to the table when it is first created. The next-extent size is the number of kilobytes allocated to the table when the initial extent, and every extent thereafter, becomes full.

Blobspaces do not use extents.

For specific instructions on how to specify and calculate the size of an extent, see your *IBM® Informix® Performance Guide*.

- Extent size
  The default size for first and next extents is 16 kilobytes. If this transforms to fewer than 4 pages in a particular dbspace, the database server uses the minimum extent size of 4 pages. If a dbspace has a size of 8 kilobytes, which transforms to 2 pages, the database server increases the extent size to 32 kilobytes.
- Page Types Within a Table Extent
- Page Types Within an Index Extent

Extent size

The default size for first and next extents is 16 kilobytes. If this transforms to fewer than 4 pages in a particular dbspace, the database server uses the minimum extent size of 4 pages. If a dbspace has a size of 8 kilobytes, which transforms to 2 pages, the database server increases the extent size to 32 kilobytes.

The maximum size of an extent is 2**31 pages, equivalent to the maximum chunk size.

If the chunk is smaller than the maximum size, the maximum extent size depends on the contiguous space available in the chunk.

Tblspaces that hold *index fragments* follow different rules for extent size. The database server bases the extent size for these tblspaces on the extent size for the corresponding table fragment. The database server uses the ratio of the row size to index key size to assign an appropriate extent size for the index tblspace (see the sections on estimating index page size and fragmenting table indexes in the *IBM® Informix® Performance Guide*).

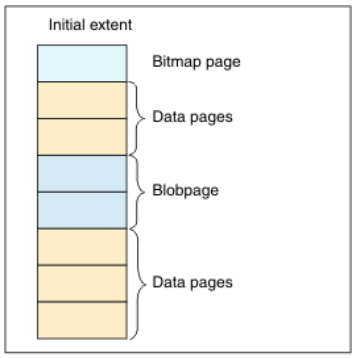
The maximum number of extents for a partition is 32767.

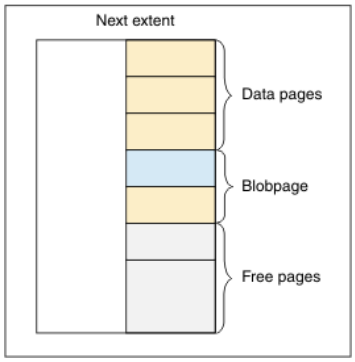
Page Types Within a Table Extent

Within the extent, individual pages contain different types of data. Extent pages for a table can be separated into the following categories:

- Data pages
  Data pages contain the data rows for the table.
- Bitmap pages
  Bitmap pages contain control information that monitors the fullness of every page in the extent.
- Blobpages
  Blobpages contain TEXT and BYTE data that is stored with the data rows in the dbspace. TEXT and BYTE data that resides in a blobspace is stored in blobpages, a structure that is completely different than the structure of a dbspace blobpage.
- Free pages
  Free pages are pages in the extent that are allocated for tblspace use, but whose function has not yet been defined. Free pages can be used to store any kind of information: data, including TEXT or BYTE data types; index; or bitmap.

Figure 1 illustrates the possible structure of a nonfragmented table with an initial-extent size of 8 pages and a next-extent size of 16 pages.
Figure 1. Extent Structure of a Table



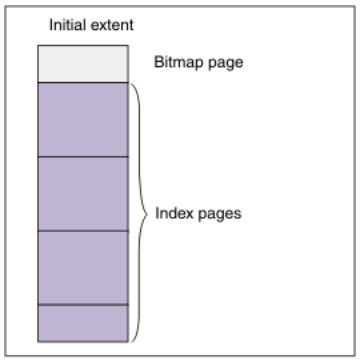


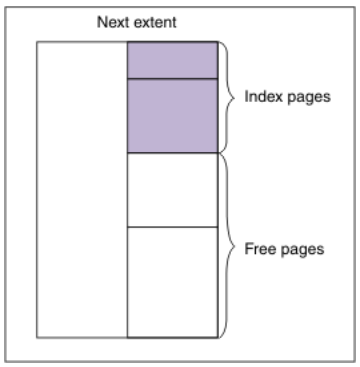
Page Types Within an Index Extent

The database server stores index pages into different tblspaces than the table with which it is associated. Within the extent, individual index pages contain different types of data. Index pages can be separated into the following categories:

- Index pages (root, branch, and leaf pages)
  Index pages contain the index information for the table.
- Bitmap pages
  Bitmap pages contain control information that monitors the fullness of every page in the extent.
- Free pages
  Free pages are pages in the extent that are allocated for tblspace use, but whose function has not yet been defined. Free pages can be used to store any kind of information: data, index, TEXT or BYTE data, or bitmap.

All indexes are detached unless you explicitly specify attached indexes.
Important: An extent that is allocated for a table fragment does not contain index pages. Index pages for a fragmented table always reside in a separate tblspace. For more information, see fragmenting table indexes in the chapter on table fragmentation and PDQ in the *IBM® Informix® Administrator's Guide*.
Figure 1 illustrates the extent structure of an index.
Figure 1. Extent Structure of an Index





Next-Extent Allocation

After the initial extent fills, the database server attempts to allocate another extent of contiguous disk space. The procedure that the database server follows is referred to as next-extent allocation.

Extents for a tblspace are tracked as one component of the tblspace **tblspace** information for the table. The maximum number of extents allocated for any tblspace is application and machine dependent because it varies with the amount of space available on the tblspace **tblspace** entry.

- Next-Extent Size
- Extent size doubling
- Lack of Contiguous Space
- Merge of Extents for the Same Table

Next-Extent Size

The number of kilobytes that the database server allocates for a next extent is, in general, equal to the size of a next extent, as specified in the SQL statement CREATE TABLE. However, the actual size of the next-extent allocation might deviate from the specified size because the allocation procedure takes into account the following three factors:

- Number of existing extents for this tblspace
- Availability of contiguous space in the chunk and dbspace
- Location of existing tblspace extents

The effect of each of these factors on next-extent allocation is explained in the paragraphs that follow and in Figure 1.

Extent size doubling

For permanent tables or user-defined temporary tables, the size of the next extent for every allocation is automatically doubled. The size doubles up to 128 kilobytes (KB). For example, if you create a table with the NEXT SIZE equal to 15 KB, the database server allocates the first extent at a size of 15 KB. The next extent is allocated at 30 KB, and the extent after that is allocated at 60 KB. When the extent size reaches 128 KB, the size is doubled only when the remaining space in the table is less than 10% of the total allocated space in the table.

For system-created temporary tables, the next-extent size begins to double after 4 extents have been added.

Lack of Contiguous Space

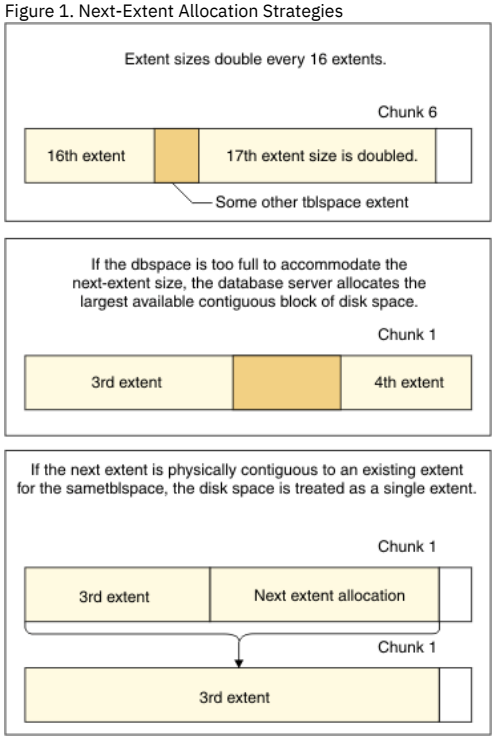
If the database server cannot find available contiguous space in the first chunk equal to the size specified for the next extent, it extends the search to the next chunk in the dbspace. Extents are not allowed to span chunks.

If the database server cannot find adequate contiguous space anywhere in the dbspace, it allocates to the table the largest available amount of contiguous space. (The minimum allocation is four pages. The default value is eight pages.) No error message is returned if an allocation is possible, even when the amount of space allocated is less than the requested amount.

Merge of Extents for the Same Table

If the disk space allocated for a next extent is physically contiguous with disk space already allocated to the same table, the database server allocates the disk space but does not consider the new allocation as a separate extent. Instead, the database server extends the size of the existing contiguous extent. Thereafter, all disk-space reports reflect the allocation as an extension of the existing extent. That is, the number of extents reported is always the number of physically distinct extents, not the number of times a next extent has been allocated plus one (the initial extent). Figure 1 illustrates extent-allocation strategies.

Figure 1. Next-Extent Allocation Strategies



After disk space is allocated to a tblspace as part of an extent, the space remains dedicated to that tblspace even if the data contained in it is deleted. For alternative methods of reclaiming this empty disk space, see your *IBM® Informix® Performance Guide*.

Structure and Storage of a Dbspace Page

The basic unit of database server I/O is a page. Page size might vary among computers.

In Informix®, the page size depends on the operating system.

- Rows in Nonfragmented Tables
- Rows in Fragmented Tables
- Recommendations on Use of Rowid
- Data-Row Format and Storage

Rows in Nonfragmented Tables

The database server can store rows that are longer than a page. The database server also supports the VARCHAR data type, which results in rows of varying length. As a result, rows do not conform to a single format.

Rows within a table are not necessarily the same length if the table contains one or more columns of type VARCHAR. In addition, the length of a row in such a table might change when an end user modifies data contained in the VARCHAR column.

The length of a row can be greater than a page.

TEXT and BYTE data is not stored within the data row. Instead, the data row contains a 56-byte descriptor that points to the location of the data. The descriptor can point to a dbspace page.

The descriptor can point to a blobspace blobpage.

For instructions about how to estimate the length of fixed-length and variable-length data rows, see your *IBM® Informix® Performance Guide*.

- Definition of Rowid
- Use of Rowids

Definition of Rowid

Informix® uses two different types of rowids to identify data in tables:

- *Serial rowid*
  These rowids are fields in a table and are assigned to tables created with the WITH ROWID option.
- *Internal rowid*
  The database server identifies each data row in a table with a unique internal rowid. This rowid identifies the location of the row within the dbspace.

  To obtain the internal rowids for a table, use the **oncheck -pD** option. For more information, see oncheck -cd and oncheck -cD commands: Check pages.

In a nonfragmented table, the term *rowid* refers to a unique 4-byte integer that defines the physical location of the row in the table. The page that contains the first byte of the data row is the page that is specified by the rowid. This page is called the data row *home page*.

Fragmented tables can also have rowids, but they are implemented in a different way. For more information on this topic, see Rows in Fragmented Tables.

Use of Rowids

Every data row in a nonfragmented table is uniquely identified by an unchanging rowid. When you create an index for a nonfragmented table, the rowid is stored in the index pages associated with the table to which the data row belongs. When the database server requires a data row, it searches the index to find the key value and uses the corresponding rowid to locate the requested row. If the table is not indexed, the database server might sequentially read all the rows in the table.

Eventually, a row might outgrow its original storage location. If this occurs, a *forward pointer* to the new location of the data row is left at the position defined by the rowid. The forward pointer is itself a rowid that defines the page and the location on the page where the data row is now stored.

Rows in Fragmented Tables

Unlike rows in a nonfragmented table, the database server does *not* assign a rowid to rows in fragmented tables. If you want to access data by rowid, you must explicitly create a rowid column as described in your *IBM® Informix® Performance Guide*. If user applications attempt to reference a rowid in a fragmented table that does not contain a rowid that you explicitly created, the database server returns an appropriate error code to the application.

- Access to Data in Fragmented Tables with Rowid

Access to Data in Fragmented Tables with Rowid

From the viewpoint of an application, the functionality of a rowid column in a fragmented table is identical to the rowid of a nonfragmented table. However, unlike the rowid of a nonfragmented table, the database server uses an index to map the rowid to a physical location.

When the database server accesses a row in a fragmented table using the rowid column, it uses this index to look up the physical address of the row before it attempts to access the row. For a nonfragmented table, the database server uses direct physical access without an index lookup. As a consequence, accessing a row in a fragmented table using rowid takes slightly longer than accessing a row using rowid in a nonfragmented table. You should also expect a small performance impact on the processing of inserts and deletes due to the cost of maintaining the rowid index for fragmented tables.

Primary-key access can lead to significantly improved performance in many situations, particularly when access is in parallel.

Recommendations on Use of Rowid

It is recommended that application developers use primary keys as a method of access rather than rowids. Because primary keys are defined in the ANSI specification of SQL, using them to access data makes your applications more portable.

For a complete description on how to define and use primary keys to access data, see the *IBM® Informix® Guide to SQL: Reference* and the *IBM Informix Guide to SQL: Tutorial*.

Data-Row Format and Storage

The variable length of a data row has the following consequences for row storage:

- A page might contain one or more whole rows.
- A page might contain portions of one or more rows.
- A page might contain a combination of whole rows and partial rows.
- An updated row might increase in size and become too long to return to its original storage location in a row.

The following paragraphs describe the guidelines that the database server follows during data storage.

Storage of Row

To minimize retrieval time, rows are not broken across page boundaries unnecessarily. Rows that are shorter than a page are always stored as whole rows. A page is considered *full* when the count of free bytes is less than the number of bytes needed to store a row of maximum size.

Location of Rows

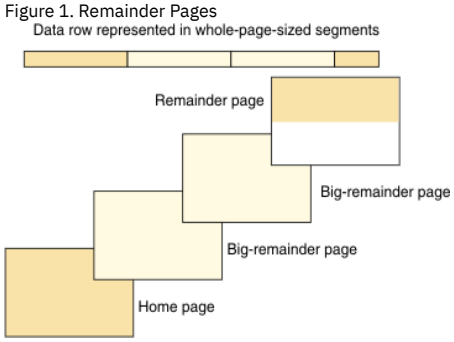
When the database server receives a row that is longer than a page, the row is stored in as many whole pages as required. The database server then stores the trailing portion in less than a full page.

The page that contains the first byte of the row is the row home page. The number of the home page becomes the logical page number contained in the rowid. Each full page that follows the home page is referred to as a big-remainder page. If the trailing portion of the row is less than a full page, it is stored on a remainder page.

After the database server creates a remainder page to accommodate a long row, it can use the remaining space in this page to store other rows.

Figure 1 illustrates the concepts of home page, big-remainder page, and remainder page.

Figure 1. Remainder Pages



Page Compression

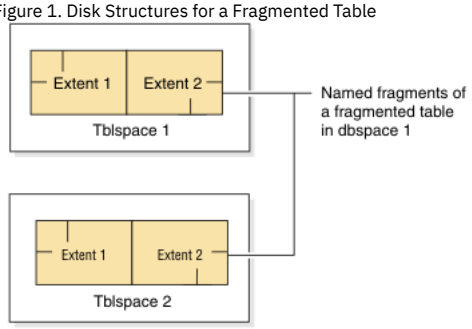
Over time, the free space on a page can become fragmented. When the database server attempts to store data, it first checks row length against the number of free bytes on a page to determine if the row fits. If adequate space is available, the database server checks if the page contains adequate contiguous free space to hold the row (or row portion). If the free space is not contiguous, the database server calls for page compression.

Structure of Fragmented Tables

Although table fragmentation is transparent to applications, as database server administrator you should be aware of how the database server allocates disk space for table fragments and how the database server identifies rows in those fragments.

Each table fragment has its own tblspace with a unique *tblspace_id* or *fragment_id*. Figure 1 shows the disk allocation for a fragmented table that resides in named fragments of the same dbspace.

Figure 1. Disk Structures for a Fragmented Table



Attached Indexes

With an attached index, the index and data are fragmented in the same way. You can decide whether to store the index pages with the corresponding data pages in the same dbspace or store them in separate dbspaces. For information on choosing a fragmentation strategy, see the *IBM® Informix® Performance Guide*.

Detached Indexes

For detached indexes, the table fragment and index fragment are stored in tblspaces in separate dbspaces.

Structure of B-Tree Index Pages

This section provides general information about the structure of B-tree index pages. It is designed as an overview for the interested reader. For more information on B-tree indexes, see your *IBM® Informix® Performance Guide*.

- Definition of B-tree terms
  The database server uses a B-tree structure to organize index information.
- Logical Storage of Indexes
- Functional Indexes

Related reference:
FILLFACTOR configuration parameter

Definition of B-tree terms

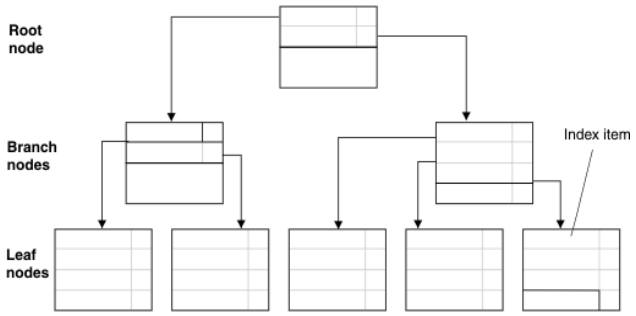
The database server uses a B-tree structure to organize index information.

Figure 1 shows that a fully developed B-tree index is composed of the following three different types of index pages or nodes:

- One *root node*
  A root node contains node pointers to branch nodes.
- Two or more *branch nodes*
  A branch node contains pointers to leaf nodes or other branch nodes.
- Many *leaf nodes*
  A leaf node contains index items and horizontal pointers to other leaf nodes.

Each node serves a different function. The following sections describe each node and the role that it plays in indexing.

Figure 1. Full B-Tree Structure



Index items

The fundamental unit of an index is the *index item*. An index item contains a key value that represents the value of the indexed column for a particular row. An index item also contains rowid information that the database server uses to locate the row in a data page.

Index nodes

A node is an index page that stores a group of index items.

Forest of trees indexes as alternatives to traditional B-Tree indexes

Unlike a traditional B-tree index, a forest of trees index is a large B-tree index that is divided into smaller subtrees with multiple root nodes and fewer levels. You can create a forest of trees index as an alternative to a B-tree index when you want to alleviate root node contention and allow more concurrent users to access the index without waiting.

Related information:
Forest of trees indexes

Logical Storage of Indexes

This section presents an overview of how the database server creates and fills an index.

- Creation of Root and Leaf Nodes
- Creation of branch nodes
- Duplicate Key Values
- Key-Value Locking
- Adjacent Key Locking
- Freed Index Pages
- Filling Indexes
- Calculating the Length of Index Items

Creation of Root and Leaf Nodes

When you create an index for an empty table, the database server allocates a single index page. This page represents the root node and remains empty until you insert data in the table.

At first, the root node functions in the same way as a leaf node. For each row that you insert into the table, the database server creates and inserts an index item in the root node. Figure 1 illustrates how a root node appears before it fills.

Figure 1. Root Node

Root node 1

Albertson	rowid information
Baxter	rowid information
Beatty	rowid information
Currie	rowid information
Keyes	rowid information
Lawson	rowid information
Mueller	rowid information

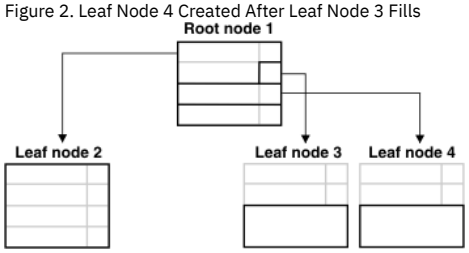
When the root node becomes full of index items, the database server splits the root node by performing the following steps:

- Creates two leaf nodes
- Moves approximately half of the root-node entries to each of the newly created leaf nodes
- Puts pointers to leaf nodes in the root node

As you add new rows to a table, the database server adds index items to the leaf nodes. When a leaf node fills, the database server creates a new leaf node, moves part of the contents of the full index node to the new node, and adds a node pointer to the new leaf node in the root node.

For example, suppose that leaf node 3 in Figure 2 becomes full. When this situation occurs, the database server adds yet another leaf node. The database server moves part of the records from leaf node 3 to the new leaf node, as Figure 2 shows.

Figure 2. Leaf Node 4 Created After Leaf Node 3 Fills



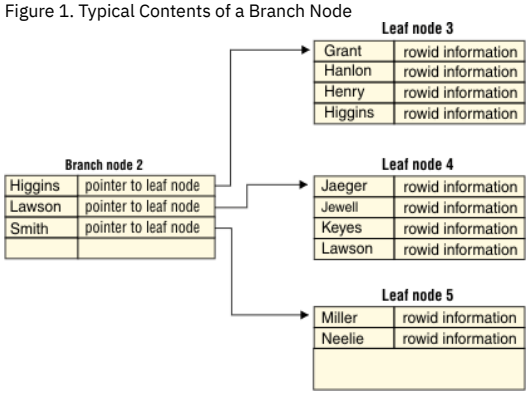
Creation of branch nodes

Eventually, as you add rows to the table, the database server fills the root node with node pointers to all the existing leaf nodes. When the database server splits yet another leaf node, and the root node has no room for an additional node pointer, the following process occurs.

The database server splits the root node and divides its contents among two newly created branch nodes. As index items are added, more and more leaf nodes are split, causing the database server to add more branch nodes. Eventually, the root node fills with pointers to these branch nodes. When this situation occurs, the database server splits the root node again. The database server then creates yet another branch level between the root node and the lower branch level. This process results in a four-level tree, with one root node, two branch levels, and one leaf level. The B-tree structure can continue to grow in this way to a maximum of 20 levels.

Branch nodes can point either to other branch nodes below them (for large indexes of four levels or more) or to leaf nodes. In Figure 1, the branch node points to leaf nodes only. The first item in the left branch node contains the same key value as the largest item in the leftmost leaf node and a node pointer to it. The second item contains the largest item in the next leaf node and a node pointer to it. The third item in the branch node contains only a pointer to the next higher leaf node. Depending on the index growth, this third item can contain the actual key value in addition to the pointer at a later point during the life span of the index.

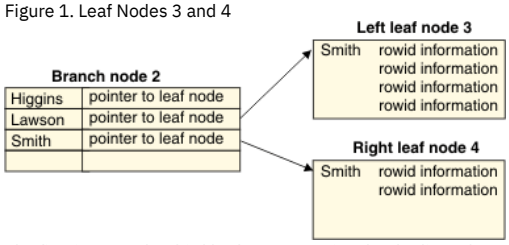
Figure 1. Typical Contents of a Branch Node



Duplicate Key Values

Duplicate key values occur when the value of an indexed column is identical for multiple rows. For example, suppose that the third and fourth leaf nodes of a B-tree structure contain the key value `Smith`. Suppose further that this value is duplicated six times, as Figure 1 illustrates.

Figure 1. Leaf Nodes 3 and 4



The first item on the third leaf page contains the duplicate key value, `Smith`, and the rowid information for the first physical row in the table that contains the duplicate key value. To conserve space, the second item does not repeat the key value `Smith` but instead contains just the rowid information. This process continues throughout the page; no other key values are on the leaf, only rowid information.

The first item on the fourth leaf page again contains the duplicated key value and rowid information. Subsequent items contain only rowid information.

Now consider the branch node. The third item in the branch node contains the same key value and rowid as the largest item in the third leaf node and a node pointer to it. The fourth item would contain only a node pointer to the fourth leaf node, thus saving the space of an additional duplicate key value.

Key-Value Locking

To increase concurrency, the database server supports *key-value* locking in the B-tree index. Key-value locking locks only the value of the key instead of the physical location in the B-tree index.

One of the most important uses for key-value locking is to assure that a unique key remains unique through the end of the transaction that deleted it. Without this protection mechanism, user A might delete a unique key within a transaction, and user B might insert a row with the same key before the transaction commits. This scenario makes rollback by user A impossible. Key-value locking prevents user B from inserting the row until the end of user A's transaction.

Adjacent Key Locking

With Repeatable Read isolation level, the database server is required to protect the *read set*. The read set consists of the rows that meet the filters in the WHERE clause of the query. To guarantee that the rows do not change, the database server obtains a lock on the index item that is adjacent to the right-most item of the read set.

Freed Index Pages

When the database server physically removes an index item from a node and frees an index page, the freed page is reused.

Filling Indexes

When you create an index, you can specify how densely or sparsely filled you want the index. The index fill factor is a percentage of each index page that will be filled during the index build. Use the FILLFACTOR option of the CREATE INDEX statement or the FILLFACTOR configuration parameter to set the fill factor. This option is particularly useful for indexes that you do not expect to grow after they are built. For additional information about the FILLFACTOR option of the CREATE INDEX statement, see the *IBM® Informix® Guide to SQL: Syntax*.

Calculating the Length of Index Items

For data types other than VARCHAR, the length of an index item is calculated by adding the length of the key value plus 5 bytes for each rowid information associated with the key value.

The key values in an index are typically of fixed length. If an index holds the value of one or more columns of the VARCHAR data type, the length of the key value is at least the sum of the length-plus-one of each VARCHAR value in the key.

In Informix®, the maximum length of a key value is 390 bytes. The combined size of VARCHAR columns that make up a key must be less than 390, minus an additional byte for each VARCHAR column. For example, the key length of the index that the database server builds for the following statements equals 390, or `((255+1) + (133+1))`:

```
CREATE TABLE T1 (c1 varchar(255, 10), c2 varchar(133, 10));
CREATE INDEX I1 on T1(c1, c2);
```

Functional Indexes

A *functional index* is one in which all keys derive from the results of a function. If you have a column of pictures, for example, and a function to identify the predominant color, you can create an index on the result of the function. Such an index would enable you to quickly retrieve all pictures having the same predominant color, without re-executing the function.

A functional index uses the same B-tree structure as any other B-tree index. The only difference is that the determining function is applied during an insert or an update whenever the column that is the argument to the function changes. For more information on the nature of functional indexes, refer to your *IBM® Informix® Performance Guide*.

To create a functional index, use the CREATE FUNCTION and CREATE INDEX statements. For more information on these statements, refer to the *IBM Informix Guide to SQL: Syntax*.

Structure of R-Tree Index Pages

An index structure that relies on one-dimensional ordering of key values does not work for spatial data; for example, two dimensional geometric shapes such as circles, squares, and triangles. Efficient retrieval of spatial data, such as the data used in geographic information systems (GIS) and computer-aided design (CAD) applications, requires an access method that handles multidimensional data. The database server implements an R-tree index to access spatial data efficiently. For information about the structure of index pages, refer to the *IBM® Informix® R-Tree Index User's Guide*.

Storage of Simple Large Objects

This section explains the structures and storage techniques that the database server uses to store simple large objects (TEXT or BYTE data).

- Structure of a Blobspace
- Structure of a Dbspace Blobpage
- Simple-Large-Object Storage and the Descriptor
- Blobspace Page Types
- Structure of a Blobspace Blobpage

Structure of a Blobspace

When you create a blobspace, you can specify the effective size of the data pages, which are called blobpages. The blobpage size for the blobspace is specified when the blobspace is created. Blobpage size must be a multiple of page size. (For information on determining database server page size, see the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*.) All blobpages within a blobspace are the same size, but the size of the blobpage can vary between blobspaces. Blobpage size can be greater than the page size because data stored in a blobspace is never written to the page-sized buffers in shared memory.

The advantage of customizing the blobpage size is storage efficiency. Within a blobspace, TEXT and BYTE data is stored in one or more blobpages, but simple large objects do not share blobpages. Storage is most efficient when the TEXT or BYTE data is equal to or slightly smaller than the blobpage size.

The blobspace free-map pages and bitmap pages are the size specified as a database server page, which enables them to be read into shared memory and to be logged.

When the blobspace is first created, it contains the following structures:

- Blobspace free-map pages
- The blobspace bitmap that tracks the free-map pages
- Unused blobpages

Structure of a Dbspace Blobpage

TEXT or BYTE data that is stored in the dbspace is stored in a blobpage. The structure of a dbspace blobpage is similar to the structure of a dbspace data page. The only difference is an extra 12 bytes that can be stored along with the TEXT or BYTE data in the data area.

Simple large objects can share dbspace blobpages if more than one simple large object can fit on a single page, or if more than one trailing portion of a simple large object can fit on a single page.

For a discussion of how to estimate the number of dbspace blobpages needed for a specific table, see your *IBM® Informix® Performance Guide*.

Each segment of TEXT or BYTE data stored in a dbspace page might be preceded by up to 12 bytes of information that does not appear on any other dbspace page. These extra bytes are overhead.

Simple-Large-Object Storage and the Descriptor

Data rows that include TEXT or BYTE data do not include the data in the row itself. Instead, the data row contains a 56-byte descriptor with a forward pointer (rowid) to the location where the first segment of data is stored.

The descriptor can point to one of the following items:

- A page (if the data is stored in a dbspace)
- A blobpage (if the data is stored in a blobspace)

- Creation of Simple Large Objects
- Deletion or Insertion of Simple Large Objects
- Size Limits for Simple Large Objects

Creation of Simple Large Objects

When a row that contains TEXT or BYTE data is to be inserted, the simple large objects are created first. After the simple large objects are written to disk, the row is updated with the descriptor and inserted.

Deletion or Insertion of Simple Large Objects

The database server cannot modify simple large objects. It can only insert or delete them. Deleting a simple large object means that the database server frees the space consumed by the deleted object for reuse.

When TEXT or BYTE data is updated, a new simple large object is created, and the data row is updated with the new blob descriptor. The old image of the row contains the descriptor that points to the obsolete value for the simple large object. The space consumed by the obsolete simple large object is freed for reuse after the update is committed. Simple large objects are automatically deleted if the rows that contain their blob descriptors are deleted. (Blobpages that stored a deleted simple large object are not available for reuse until the logical log that contains the original INSERT record for the deleted simple large object is backed up. For more information, see backing up logical-log files to free blobpages in the chapter on what is the logical log in the *IBM® Informix® Administrator's Guide*.)

Size Limits for Simple Large Objects

The largest simple large object that the blob descriptor can accommodate is (2^{31} - 1), or about 2 gigabytes.

Blobspace Page Types

Every blobspace chunk contains three types of pages:

- A blobspace free-map page
- A bitmap page
- Blobpages

Blobspace Free-Map Page

The blobspace free-map page identifies unused blobpages so that the database server can allocate them as part of simple-large-object creation. When a blobpage is allocated, the free-map entry for that page is updated. All entries for a single simple large object are linked.

A blobspace free-map page is the size of one database server page. Each entry on a free-map page is 8 bytes, stored as two 32-bit words, as follows:

- The first bit in the first word specifies whether the blobpage is free or used.
- The next 31 bits in the first word identify the logical-log file that was current when this blobpage was written. (This information is needed for logging TEXT or BYTE data.)
- The second word contains the tblspace number associated with the simple large object stored on this page.

The number of entries that can fit on a free-map page depends on the page size of your computer. The number of free-map pages in a blobspace chunk depends on the number of blobpages in the chunk.

Blobspace Bitmap Page

The blobspace bitmap page tracks the fullness and number of blobspace free-map pages in the chunk. Each blobspace bitmap page is capable of tracking a quantity of free-map pages. The size of the blobspace bitmap page depends on the size of the system page. If the system page is 2K, the blobspace bitmap page can track 2,032,128 blobpages. If the system page is 4K, the blobspace bitmap page can track 8,258,048 blobpages.

Blobpage

The blobpage contains the TEXT or BYTE data. Blobpage size is specified by the database server administrator who creates the blobspace. Blobpage size is specified as a multiple of the page size.

Structure of a Blobspace Blobpage

The storage strategy used to store simple large objects in a blobspace differs from the dbspace storage strategy. The database server does not combine whole simple large objects or portions of a simple large object on a single blobspace blobpage. For example, if blobspace blobpages are 24 kilobytes each, a simple large object that is 26 kilobytes is stored on two 24-kilobyte pages. The extra 22 kilobytes of space remains unused.

The structure of a blobpage includes a blobpage header, the TEXT or BYTE data, and a page-ending time stamp. The blobpage header includes, among other information, the page-header time stamp and the blob time stamp associated with the forward pointer in the data row. If a simple large object is stored on more than one blobpage, a forward pointer to the next blobpage and another blob time stamp are also included in the blobpage header.

Sbspace Structure

An sbspace is similar to a blobspace except that it holds smart large objects.

When an sbspace is created in a database, it contains an sbspace descriptor. Each sbspace chunk contains the following structures:

- Sbspace chunk descriptors
- Chunk free-page list
- An sbspace metadata area (up to one for each chunk)
- Reserved data areas (up to two for each chunk)
- User-data areas (up to two for each chunk)

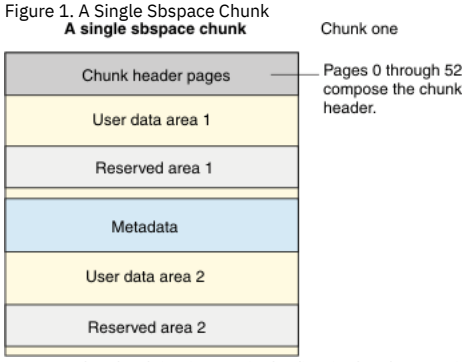
For best performance, it is recommended that the metadata area be located in the middle of the sbspace. The database server automatically places the metadata area in the correct location. However, to specify the location of the metadata area, specify the **-Mo** flag in the **onspaces** command.

If you do not specify the size of the metadata area in the **-Ms** flag of the **onspaces** command, the database server uses the value of AVG_LO_SIZE (defaults to 8 kilobytes) to calculate the size of the metadata area. For more information, see Creating an Sbspace with the -Df option.

Normally, you can let the system calculate the metadata size for you. If you want to estimate the size of the metadata area, see the chapter on table performance considerations in the *IBM® Informix® Performance Guide*.

Figure 1 illustrates the chunk structure of an sbspace as it appears immediately after the sbspace is created. Each reserved area can be allocated to either the user-data or metadata area. Reserved areas are always within the user-data area of the chunk.

Figure 1. A Single Sbspace Chunk



Because the chunk in Figure 1 is the first in the sbspace, it contains an sbspace descriptor. The chunk descriptor tblspace in **chunk one** contains information about chunk one and all chunks added to the sbspace thereafter.

- Structure of the metadata area
  An sbspace contains a metadata area for each chunk in the sbspace.
- Sbpage Structure

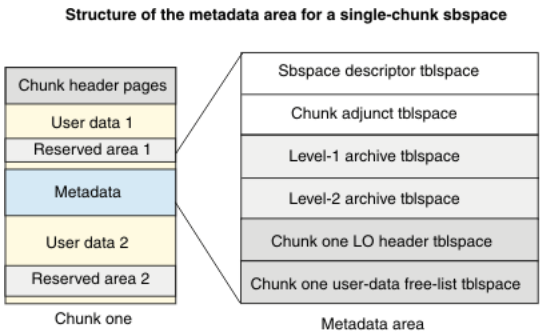
Related reference:
SBSPACENAME configuration parameter
SYSSBSPACENAME configuration parameter

Structure of the metadata area

An sbspace contains a metadata area for each chunk in the sbspace.

As with the chunk header pages, four areas are exclusive to the first chunk in a sbspace: the sbspace descriptor tblspace, the chunk adjunct tblspace, and the level-1 and level-2 archive tblspaces. The tblspace header section contains a tblspace header for each of these tblspaces (notably excluding the tblspace **tblspace**). Figure 1 shows the layout of the metadata in the single-chunk sbspace.

Figure 1. Structure of the metadata area for a single-chunk sbspace



When you specify the sbspace name in the **oncheck -ps** option, you can display the number of pages allocated and used for each tblspace in the metadata area.

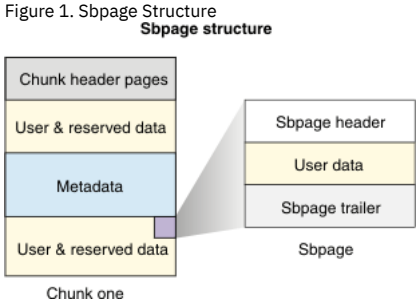
The following items describe how the metadata area grows:

- The sbspace descriptor tblspace does not grow.
- The chunk adjunct tblspace grows as chunks are added.
- The LO header tblspace grows as large objects are added to the chunk.
- The tblspace for user-data free list grows if free spaces in the chunk are heavily fragmented.

Sbpage Structure

Each sbpage is composed of three elements: an sbpage header, the actual user data itself, and an sbpage trailer. Figure 1 shows the structure of an sbpage. The sbpage header consists of the standard page header. The sbpage trailer is used to detect an incomplete write on the page and to detect page corruption.

Figure 1. Sbpage Structure



Time Stamps

The database server uses a time stamp to identify a time when an event occurred relative to other events of the same kind. The time stamp is not a literal time that refers to a specific hour, minute, or second. It is a 4-byte integer that the database server assigns sequentially.

Database and Table Creation: What Happens on Disk

This section explains how the database server stores data related to the creation of a database or table and allocates the disk structures that are necessary to store your data.

- Database Creation
- Table Creation

Database Creation

After the root dbspace exists, users can create a database. The paragraphs that follow describe the major events that occur on disk when the database server adds a new database.

- Disk-Space Allocation for System Catalog Tables
- Tracking of System Catalog Tables

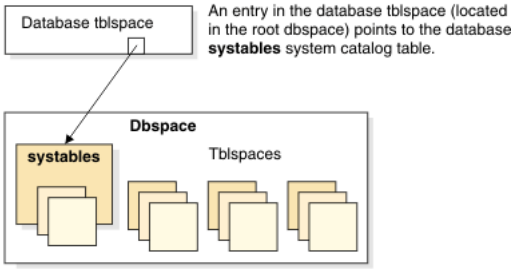
Disk-Space Allocation for System Catalog Tables

The database server searches the chunk free-list pages in the dbspace, looking for free space in which to create the system catalog tables. For each system catalog table, in turn, the database server allocates eight contiguous pages, the size of the initial extent of each system catalog table. The tables are created individually and do not necessarily reside next to each other in the dbspace. They can be located in different chunks. As adequate space is found for the initial extent of each table, the pages are allocated, and the associated chunk free-list page is updated.

Tracking of System Catalog Tables

The database server tracks newly created databases in the database tblspace, which resides in the root dbspace. An entry describing the database is added to the database tblspace in the root dbspace. (See Structure of the Database Tblspace.) For each system catalog table, the database server adds a one-page entry to the tblspace **tblspace** in the dbspace where the database was built. (See Structure of the Tblspace Tblspace.) Figure 1 illustrates the relationship between the database tblspace entry and the location of the **systables** system catalog table for the database.

Figure 1. New Databases



For instructions on how to list your databases after you create them, see monitoring databases in the chapter on managing database-logging status in the *IBM® Informix® Administrator's Guide*.

Table Creation

After the root dbspace exists, and a database has been created, users with the necessary SQL privileges can create a database table. When users create a table, the database server allocates disk space for the table in units called extents (see what is an extent in the chapter on where data is stored in the *IBM® Informix® Administrator's Guide*). The paragraphs that follow describe the major events that occur when the database server creates a table and allocates the initial extent of disk space.

- Disk-Space Allocation
- Entry in the Tblspace Tblspace
- Entries in the System Catalog Tables
- Creation of a Temporary Table

Disk-Space Allocation

The database server searches the chunk free-list pages in the dbspace for contiguous free space equal to the initial extent size for the table. When adequate space is found, the pages are allocated, and the associated chunk free-list page is updated.

If the database server cannot find adequate contiguous space anywhere in the dbspace, it allocates to the table the largest available amount of contiguous space. No error message is returned if an allocation is possible, even when the amount of space allocated is less than the requested amount. If the minimum extent size cannot be allocated, an error is returned. (Extents cannot span two chunks.)

Entry in the Tblspace Tblspace

The database server adds a one-page entry for this table to the tblspace **tblspace** in this dbspace. The tblspace number assigned to this table is derived from the logical page number in the tblspace **tblspace** where the table is described. See Tblspace Numbers.

The tblspace number indicates the dbspace where the tblspace is located. Tblspace extents can be located in any of the dbspace chunks.

If you must know exactly where the tblspace extents are located, execute the **oncheck -pe** command for a listing of the dbspace layout by chunk.

Entries in the System Catalog Tables

The table itself is fully described in entries stored in the system catalog tables for the database. Each table is assigned a table identification number or *tabid*. The tabid value of the first user-defined table object in a database is always `100`. (The object whose tabid = 100 might also be a view, synonym, or a sequence.) For a complete discussion of the system catalog, see the *IBM® Informix® Guide to SQL: Reference*.

A table can be located in a dbspace that is different than the dbspace that contains the database. The tblspace itself is the sum of allocated extents, not a single, contiguous allocation of space. The database server tracks tblspaces independently of the database.

Creation of a Temporary Table

The tasks involved in creating temporary tables are similar to the tasks that the database server performs when it adds a new permanent table. The key difference is that temporary tables do not receive an entry in the system catalog for the database. For more information, see the section defining a temporary table, in the chapter on where data is stored in the *IBM® Informix® Administrator's Guide*.

Interpreting Logical-Log Records

In This Chapter

To display the logical-log records that the logical-log files contain, use the **onlog** utility.

This chapter provides the following information:

- Brief guidance on reading logical-log records
- A listing of the different logical-log record types

In general, you do not need to read and interpret your logical-log files. However, **onlog** output is useful in debugging situations. For example, you might want to use **onlog** to track a specific transaction or to see what changes the database server made to a specific tblspace. You can also use **onlog** to investigate the cause of an error that occurs during a rollforward. For more information, see onlog: Display Logical-Log Contents.

About Logical-Log Records

Most SQL statements generate multiple logical-log records. Interpreting logical-log records is more complicated when the database server records the following events in the logical log:

- A transaction that drops a table or index
- A transaction that rolls back
- A checkpoint in which transactions are still active
- A distributed transaction

The following sections discuss the logical-log records for these events.

Transactions That Drop a Table or Index

Once the database server drops a table or index from a database, it cannot roll back that drop operation. If a transaction contains a DROP TABLE or DROP INDEX statement, the database server handles this transaction as follows:

1. The database server completes all the other parts of the transaction and writes the relevant logical-log records.
2. The database server writes a BEGCOM record to the logical log and the records associated with the DROP TABLE or DROP INDEX (DINDEX, for example).

3. The database server writes a COMMIT record.

If the transaction is terminated unexpectedly after the database server writes the BEGCOM record to the logical log, the database server rolls *forward* this transaction during recovery because it cannot roll back the drop operation.

Transactions That Are Rolled Back

When a rollback occurs, the database server generates a compensation-log record (CLR) for each record in the logical log that is rolled back. The database server uses the CLRs if a system failure takes place *during a rollback*. The CLRs provide the database server with information on how far the rollback progressed before the failure occurred. In other words, the database server uses the CLRs to log the rollback.

If a CLR contains the phrase `includes next record`, the next log record that is printed is included within the CLR log record as the compensating operation. Otherwise, you must assume that the compensating operation is the logical undo of the log record to which the **link** field of the CLR points.

Checkpoints with Active Transactions

If any transactions are active at the time of a checkpoint, checkpoint records include subentries that describe each of the active transactions using the following columns:

- Log begin (decimal format)
- Transaction ID (decimal format)
- Unique log number (decimal format)
- Log position (hexadecimal format)
- User name

Distributed Transactions

When distributed transactions (transactions that span multiple database servers) generate log records, they are slightly different than nondistributed transactions. You might need to read and interpret them to determine the state of the transaction on both database servers if a failure occurs as a transaction was committing.

The following log records are involved in distributed transactions:

- BEGPREP
- ENDTRANS
- HEURTX
- PREPARE
- TABLOCKS

For more information about this type of logical-log record, see the material on two-phase commit and logical-log records in the *IBM® Informix® Administrator's Guide*.

If you are performing distributed transactions with TP/XA, the database server uses an XAPREPARE record instead of a PREPARE record.

Logical-Log Record Structure

Each logical-log record has *header* information. Depending on the record type, additional columns of information also appear in the output, as explained in Logical-log record types and additional columns.

- Logical-Log Record Header
- Logical-log record types and additional columns
  In addition to the six header columns that display for every record, some record types display additional columns of information. The information that appears varies, depending on record type.
- Log Record Types for Smart Large Objects

Logical-Log Record Header

Table 1 contains sample output to illustrate the header columns that display for a logical-log record.

Table 1. Sample Output from onlog

addr	len	type	xid	id	link
2c018	32	BEGIN	6	3	0
2c038	140	HDELETE	6	0	2c018
2c0c4	64	DELITEM	6	0	2c038
2c104	40	DELITEM	6	0	2c0c4
2c12c	72	HDELETE	6	0	2c104
2c174	44	DELITEM	6	0	2c12c
2c1a0	72	HDELETE	6	0	2c174
2c1e8	44	DELITEM	6	0	2c1a0
2c214	64	HDELETE	6	0	2c1e8
2c254	56	DELITEM	6	0	2c214
2c28c	48	DELITEM	6	0	2c254
2c2bc	24	PERASE	6	0	2c28c
2c2d4	20	BEGCOM	6	0	2c2bc
2c2e8	24	ERASE	6	0	2c2d4
2c300	28	CHFREE	6	0	2c2e8
2c31c	24	COMMIT	6	0	2c300

Table 2 defines the contents of each header column.

Table 2. Definition of onlog Header Columns

Header Field	Contents	Format
addr	Log-record address (log position)	Hexadecimal
len	Record length in bytes	Decimal
type	Record-type name	ASCII
xid	Transaction number	Decimal
id	Logical-log number	Decimal
link	Link to the previous record in the transaction	Hexadecimal

Logical-log record types and additional columns

In addition to the six header columns that display for every record, some record types display additional columns of information. The information that appears varies, depending on record type.

The following table lists all the record types and their additional columns.

The **Action** column indicates the type of database server action that generated the log entry. The **Additional Columns** and **Format** columns describe what information appears for each record type in addition to the header described in Logical-Log Record Header.

Table 1. Logical-Log Record Types

Record Type	Action	Additional Columns and Format
ADDCHK	Add chunk.	• chunk number - Decimal • chunk name - ASCII
ADDDBS	Add dbspace.	• dbspace name - ASCII
ADDITEM	Add item to index.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • logical page - Decimal • key number - Decimal • key length - Decimal
ADDLOG	Add log.	• log number - Decimal • log size (pages) - Decimal • pageno - Hexadecimal

Record Type	Action	Additional Columns and Format
ALLOCGENPG	Allocate a generic page.	• tblspace ID - Decimal • rowid - Decimal • slot flags and length - Decimal • page version if delete - Decimal • flags, vimage record - Decimal • rowid for previous - Decimal • data - ASCII
ALTERDONE	Alter of fragment complete.	• tblspace ID - Hexadecimal • physical page number previous page - Hexadecimal • logical page number - Decimal • version of alter - Decimal
ALTSPCOLSNEW	Changed columns in an alter table.	• number of columns - Decimal • special column list - array
ALTSPCOLSOLD	Changed columns in an alter table.	• number of columns - Decimal • special column list - array
BADIDX	Bad index	• tblspace ID - Hexadecimal
BEGCOM	Begin commit.	• (None) - (None)
BEGIN	Begin work.	• date - Decimal • time - Decimal • SID - Decimal • user - ASCII
BEGPREP	Written by the coordinator database server to record the start of the two-phase commit protocol.	• flags - Decimal (Value is 0 in a distributed transaction.) • number of participants - Decimal
BEGWORK	Begin a transaction.	• begin transaction time - Decimal • user ID - Decimal • process ID - Decimal
BFRMAP	Simple-large-object free-map change.	• tblspace ID - Hexadecimal • bpageno - Hexadecimal • status USED/FREE log ID - Decimal • prev page - Hexadecimal
BLDCL	Build tblspace.	• tblspace ID - Hexadecimal • fextsize - Decimal • nextsize - Decimal • row size - Decimal • ncolumns - Decimal • table name - ASCII
BMAPFULL	Bitmap modified to prepare for alter.	• tblspace ID - Hexadecimal • bitmap page num - Decimal
BMAP2TO4	2-bit bitmap altered to two 4-bit bitmaps.	• tblspace ID - Hexadecimal • 2-bit bitmap page number - Decimal • flags - Decimal
BSPADD	Add blobspace.	• blobspace name - ASCII
BTCPYBCK	Copy back child key to parent.	• tblspace ID - Hexadecimal • parent logical page - Decimal • child logical page - Decimal • slot - Decimal • rowoff - Decimal • key number - Decimal
BTMERGE	Merge B-tree nodes.	• tblspace ID - Hexadecimal • parent logical page - Decimal • left logical page - Decimal • right logical page - Decimal • left slot - Decimal • left rowoff - Decimal • right slot - Decimal • right rowoff - Decimal • key number - Decimal

Record Type	Action	Additional Columns and Format
BTSHUFFL	Shuffle B-tree nodes.	• tblspace ID - Hexadecimal • parent logical page - Decimal • left logical page - Decimal • right logical page - Decimal • left slot - Decimal • left rowoff - Decimal • key number - Decimal • flags - Hexadecimal
BTSPLIT	Split B-tree node.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • parent logical page - Decimal • left logical page - Decimal • right logical page - Decimal • infinity logical page - Decimal • rootleft logical page - Decimal • midsplit - Decimal • key number - Decimal • key length - Decimal
CDINDEX	Create detached index.	• database name - ASCII • owner - ASCII • table name - ASCII • index name - ASCII
CDR	Captures the set of table columns modified by an update statement such as a *bitvector*. This log record allows Enterprise Replication to capture only the changed data to avoid transmitting the unchanged columns to a target site. In the example, the first six columns of the table are unchanged (6 leftmost bits in the **bitvector** are 0), the seventh and eighth columns have been updated (seventh and eighth bits are 1), and so on. The onlog output displays as many bits of bitvector as fit in a single line of the output. To see the entire **bitvector** displayed in hexadecimal, use the **onlog -l** command.	• name of CDR record - ASCII • partition number - Hexadecimal • bitvector - Binary Sample **onlog** output for CDR log record: `adr len type xid id link` `40 36 CDR 14 0 18` `name partno bitvector` `UPDCOLS 10009a 000000110100110100`
CHALLOC	Chunk extent allocation.	• pageno - Hexadecimal • size - Hexadecimal
CHCOMBINE	Chunk extent combine.	• pageno - Hexadecimal
CHFREE	Chunk extent free.	• pageno - Hexadecimal • size - Hexadecimal
CHKADJUP	Update chunk adjunct on disk. The database server writes this record when it moves space from the reserved area to the metadata or user-data area or when the user adds an sbspace chunk.	• chunk number - Integer • ud1_start_page - Integer • ud1_size - Integer • md_start_page - Integer • md_size - Integer • ud2_start_page - Integer • ud2_size - Integer • flags - Hexadecimal
CHPHYLOG	Change physical-log location.	• pageno - Hexadecimal • size in kilobytes - Hexadecimal • dbspace name - ASCII
CHRESERV	Reserve extent for metadata stealing. This record is written when you add an sbspace chunk.	• chunk number - Integer • page number - Integer • length - Integer
CHSPLIT	Chunk extent split.	• pageno - Hexadecimal
CINDEX	Create index.	• tblspace ID - Hexadecimal • low rowid - Decimal • high rowid - Decimal • index descriptor - ASCII

Record Type	Action	Additional Columns and Format
COARSELOCK	Coarse-grain locking	• tblspace ID - Hexadecimal • old coarse-locking flag value - Decimal • new coarse-locking flag value - Decimal
CKPOINT	Checkpoint.	• max users - Decimal • number of active transactions - Decimal
CLR	Compensation-log record; created during a rollback.	• (None) - (None)
CLUSIDX	Create clustered index.	• tblspace ID - Hexadecimal • key number - Decimal
COLREPAI	Adjust BYTE, TEXT, or VARCHAR column.	• tblspace ID - Hexadecimal • number of columns adjusted - Decimal
COMMIT	Commit work.	• date - Decimal • time - Decimal
COMTAB	Compact slot table on a page.	• logical page number - Decimal • number slots moved - Decimal • compressed slot pairs - ASCII
COMWORK	End a transaction and commit work.	• end transaction time - Decimal • begin transaction time - Decimal
DELETE	Delete before-image.	• tblspace ID - Hexadecimal • rowid - Hexadecimal
DELITEM	Delete item from index.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • logical page - Decimal • key number - Decimal • key length - Decimal
DERASE	Drop tblspace in down dbspace.	• tblspace number - Hexadecimal • table lock number - Decimal
DFADDEXT	New extent is added.	• partnum - Hexadecimal • offset of extent entry in list - Hexadecimal • extent size in pages - Decimal • physical address of extent - Offset and chunk no-hex
DFDRPEXT	Drop the original extent.	• partnum - Hexadecimal • offset of extent entry in list - Hexadecimal • original size of this extent - Decimal • physical address - offset and chunk no-hex
DFEND	End of defragment operation.	• partnum - Hexadecimal
DFMVPG	Move page from old extent to new extent.	• partnum - Hexadecimal • offset of new extent - Hexadecimal • logical page number of source - Hexadecimal • physical address of destination - Offset and chunk no-hex • physical address of source - Offset and chunk no-hex
DFREMDUM	Remove the dummy entries.	• partnum - Hexadecimal
DFSTART	Start of defragment operation.	• partnum - Hexadecimal
DINDEX	Drop index.	• tblspace ID - Hexadecimal • key number - Decimal
DRPBSP	Drop blobspace.	• blobspace name - ASCII
DRPCHK	Drop chunk.	• chunk number - Decimal • chunk name - ASCII
DRPDBS	Drop dbspace.	• dbspace name ASCII

Record Type	Action	Additional Columns and Format
DRPLOG	Drop log.	• log number - Decimal • log size (pages) - Decimal • pageno - Hexadecimal
ENDTRANS	Written by both the coordinator and participant database servers to record the end of the transaction. ENDTRANS instructs the database server to remove the transaction entry from its shared-memory transaction table and close the transaction. In the coordinator logical log, each BEGPREP that results in a committed transaction is paired with an ENDTRANS record. If the final decision of the coordinator is to roll back the transaction, no ENDTRANS record is written. In the participant logical log, each ENDTRANS record is paired with a corresponding HEURTX record.	• (None) - (None)
ERASE	Drop tblspace.	• tblspace ID -Hexadecimal
FREE_RE	Allocate extent from reserve extent to metadata or user-data area of an sbspace chunk.	• chunk number - Integer • page number - Integer • length - Integer • flag - Hexadecimal
HDELETE	Delete home row.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal
HEURTX	Written by a participant database server to record a heuristic decision to roll back the transaction. It should be associated with a standard ROLLBACK record indicating that the transaction was rolled back.	• flag - Hexadecimal (Value is always 1.)
HINSERT	Home row insert.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal
HUPAFT	Home row update, after-image.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal
HUPBEF	Home row update, before-image. In addition, the flag field of the HUPBEF header may include the following values: LM_PREVLSN Confirms that an LSN exists. LM_FIRSTUPD Confirms that this is the first update for this rowID by this transaction.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal • LSN (optional) - Decimal
HUPDATE	If the home row update before-images and after-images can both fit into a single page, the database server writes a single HUPDATE record. In addition, the flag field of the HUPDATE log may include the following values: LM_PREVLSN Confirms that an LSN exists. LM_FIRSTUPD Confirms that this is the first update for this rowID by this transaction.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • forward ptr rowid - Hexadecimal • old slotlen - Decimal • new slotlen - Decimal • number of pieces - Decimal • LSN (optional) - Decimal
IDXFLAGS	Index flags.	• tblspace ID - Hexadecimal • key number - Hexadecimal
INSERT	Insert after-image.	• tblspace ID - Hexadecimal • rowid - Hexadecimal
ISOSPCOMMIT	Log an isolated save-point commit.	• end transaction time - Decimal • begin transaction time - Decimal

Record Type	Action	Additional Columns and Format
LCKLVL	Locking mode (page or row).	• tblspace ID - Hexadecimal • old lockmode - Hexadecimal • new lockmode - Hexadecimal
LG_ADDBPOOL	Add a buffer pool online.	• page size in bytes - Decimal • number of buffers in the pool - Decimal • number of lru queues - Decimal • percent of lru_max_dirty - Decimal • percent of lru_min_dirty - Decimal
PTRUNCATE	Identifies an intention to truncate a table. The partitions are marked to be dropped or reused, according to the specified command option.	• tblspace ID - Hexadecimal
TRUNCATE	TRUNCATE has freed the extents and the transaction will be committed.	• tblspace ID - Hexadecimal
MVIDXND	Index node moved to allow for 2-bit to 4-bit bitmap conversion.	• tblspace ID - Hexadecimal • old page number - Decimal • new page number - Decimal • parent page number - Decimal • parent slot number - Decimal • parent slot offset - Decimal • key number - Decimal
PBDELETE	Delete tblspace blobpage.	• bpageno - Hexadecimal • status USED/FREE unique ID - Decimal
PBINSERT	Insert tblspace blobpage.	• bpageno - Hexadecimal • tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal • pbrowid - Hexadecimal
PDINDEX	Predrop index.	• tblspace ID - Hexadecimal
PGALTER	Page altered in place.	• tblspace ID - Hexadecimal • physical page number - Hexadecimal
PGMODE	Page mode modified in bitmap.	• tblspace ID - Hexadecimal • logical page number - Decimal • old mode - Hexadecimal • new mode - Hexadecimal
PERASE	Preerase old file. Mark a table that is to be dropped. The database server frees the space on the commit.	• tblspace ID - Hexadecimal
PNGPALIGN8	Use the pages in this tblspace as generic pages.	• None
PNLOCKID	Change tblspaces lockid.	• tblspace ID - Hexadecimal • old lock ID - Hexadecimal • new lock ID - Hexadecimal
PNSIZES	Set tblspace extent sizes.	• tblspace ID - Hexadecimal • fextsize - Decimal • nextsize - Decimal
PREPARE	Written by a participant database server to record the ability of the participant to commit the transaction, if so instructed.	• DBSERVERNAME of coordinator - ASCII
PTADESC	Add alter description information.	• tblspace ID - Hexadecimal • physical page number of previous page - Hexadecimal • logical page number - Decimal • number of columns added - Decimal
PTALTER	Alter of fragment begun.	• tblspace ID - Hexadecimal • physical page number previous page - Hexadecimal • logical page number - Decimal • alter desc page number - Decimal • num columns added - Decimal • version of alter - Decimal • added rowsize - Decimal

Record Type	Action	Additional Columns and Format
PTALTNEWKEYD	Update key descriptors in a tblspace header after an alter table command.	• bytes in key descriptor - Decimal • data in key descriptor - ASCII
PTALTOLDKEYD	Update key descriptors after an alter table command.	• bytes in key descriptor - Decimal • data in key descriptor - ASCII
PTCOLUMN	Add special columns to fragment.	• tblspace ID - Hexadecimal • number of columns - Decimal
PTEXTEND	Tblspace extend.	• tblspace ID - Hexadecimal • last logical page - Decimal • first physical page - Hexadecimal
PTRENAME	Rename table.	• tblspace ID - Hexadecimal • old table name - ASCII • new table name - ASCII
RDELETE	Remainder page delete.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal • hrowid (optional) - Decimal • poffset (optional) - Decimal
RENDBS	Rename dbspace.	• new dbspace name - ASCII
REVERT	Logs the reversion of a database space to a database space of an earlier version.	• type of reversion event - Decimal • arg1 - Decimal • arg2 - Decimal • arg3 - Decimal
RINSERT	Remainder page insert.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal • hrowid (optional) - Decimal • poffset (optional) - Decimal
ROLLBACK	Rollback work.	• date - Decimal • time - Decimal
ROLWORK	End a transaction and roll back work.	• end transaction time - Decimal • begin transaction time - Decimal
RSVEXTEND	Logs the extension to the reserved pages.	• number of pages - Decimal • physical page number of extent - Hexadecimal
RTREE	Logs inserts and deletions for R-tree index pages. (Other operations on R-tree indexes are physically logged.) The record subtypes are: • LEAFINS - insert item in a leaf page • LEAFDEL - delete item from leaf page	• record subtype - ASCII • index page rowid - Hexadecimal • tuple length - Decimal • base table rowid - Decimal • base table fragid - Decimal • delete flag - Decimal
RUPAFT	Remainder page update, after-image.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal
RUPBEF	Remainder page update, before-image.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • slotlen - Decimal • hrowid (optional) - Decimal • poffset (optional) - Decimal
RUPDATE	If the remainder page update before-images and after-images can both fit into a single page, the database server writes a single RUPDATE record.	• tblspace ID - Hexadecimal • rowid - Hexadecimal • forward ptr rowid - Hexadecimal • old slotlen - Decimal • new slotlen - Decimal • number of pieces - Decimal • hrowid (optional) - Decimal • poffset (optional) - Decimal

Record Type	Action	Additional Columns and Format
SBLOB	Indicates a subsystem log record for a smart large object. The various record subtypes are: • CHALLOC • CHCOMBINE • CHFREE • CHSPLIT • CREATE • DELETES • EXTEND • HDRUPD • PDELETE • PTRUNC • REFCOUNT • UDINSERT • UDINSERT_LT • UDUPAFT • UDUPAFT_LT • UDUPAFT • UDUPAFT_LT • UDWRITE • UDWRITE_LT	• Varies For more information, see Log Record Types for Smart Large Objects. Varies
SYNC	Written to a logical-log file if that log file is empty and administrator instructs the database server to switch to next log file.	• (None) - (None)
TABLOCKS	Written by either a coordinator or a participant database server. It is associated with either a BEGPREP or a PREPARE record and contains a list of the locked tblspaces (by tblspace number) held by the transaction. (In a distributed transaction, transactions are shown as the owners of locks.)	• number of locks - Decimal • tblspace number - Hexadecimal
UDINSERT	Append new user data.	• number of locks - Decimal • tblspace number - Hexadecimal
UDUPAFT	Update user data after-image if a UDWRITE is too expensive.	• chunk - Decimal • page within chunk - Hexadecimal • offset within page - Hexadecimal • data length - Hexadecimal
UDUPBEF	Update user-data before-image if a UDWRITE is too expensive.	• chunk - Decimal • page within chunk- Hexadecimal • offset within page - Hexadecimal • data length - Hexadecimal
UDWRITE	Update user data (difference image).	• chunk - Decimal • page within chunk - Hexadecimal • offset within chunk - Hexadecimal • length before write - Hexadecimal • length after write - Hexadecimal
UNDO	Header record to a series of transactions to be rolled back.	• count - Decimal
UNDOBLDC	This record is written if a CREATE TABLE statement should be rolled back but cannot be because the relevant chunk is down. When the log file is replayed, the table will be dropped.	• tblspace number - Hexadecimal
UNIQID	Logged when a new SERIAL value is assigned to a row.	• tblspace ID - Hexadecimal • unique ID - Decimal
UNIQ8ID	Logged when a new SERIAL8 value is assigned to a row.	• tblspace ID - Hexadecimal • unique ID - Decimal
UPDAFT	Update after-image.	• tblspace ID - Hexadecimal • rowid - Hexadecimal
UPDBEF	Update before-image.	• tblspace ID - Hexadecimal • rowid - Hexadecimal

Record Type	Action	Additional Columns and Format
XAPREPARE	Participant can commit this XA transaction.	• (None) - (None)

Log Record Types for Smart Large Objects

All smart-large-object log records are the SBLOB type. Each smart-large-object log record contains six header columns, described in Logical-Log Record Header; the record subtype; and additional information. The information that appears varies, depending on record subtype.

Table 1 lists all the smart-large-object record types. The **Subtype** column describes the smart-large-object record type. The **Action** column indicates the type of database server action that generated the log entry. The **Additional Columns** and **Format** columns describe what information appears for each record type.

Table 1. Record Subtypes for Smart Large Objects

Record Subtype	Action	Additional Columns	Format
CHALLOC	Allocate chunk extent.	extent [chk, page, len]	Decimal
		flags	Hexadecimal
CHCOMBINE	Combine two pages in the user-data extent list.	chunk number	Decimal
		first page	Decimal
		second page	Decimal
CHFREE	Frees chunk extent.	extent [chk, page, len]	Decimal
CHSPLIT	Split a page in the user-data extent list.	chunk number	Decimal
		UDFET page to split	Decimal
CREATE	Create smart large object.	smart-large-object ID [sbs, chk, page, oid]	Decimal
		number of extents in lomaphdr	Decimal
DELETE	Delete a smart large object at commit.	smart-large-object ID [sbs, chk, page, oid]	Decimal
EXTEND	Add extent to an extent list of a smart large object.	smart-large-object ID [sbs, chk, page, oid]	Decimal
		extent [chk, page, len]	Decimal
		lomap overflow page number	Decimal
HDRUPD	Update smart-large-object header page.	smart-large-object ID [sbs, chk, page, oid]	Decimal
		old EOF offset	String
		new EOF offset	String
		old times	Decimal
		new times	Decimal
PDELETE	Queue a smart large object for deletion at commit.	smart-large-object ID [sbs, chk, page, oid]	Decimal
PTRUNC	Queue a smart large object for truncation at commit.	smart-large-object ID [sbs, chk, page, oid]	Decimal
		old offset	String
		new offset	String
REFCOUNT	Increment or decrement the reference count of a smart large object.	smart-large-object ID [sbs, chk, page, oid]	Decimal
		1 if increment; 0 if decrement	Decimal
UDINSERT,	Append new user data.	chunk	Decimal
UDINSERT_LT		page within chunk	Decimal
		offset within page	Decimal
		data length	Decimal
UDUPAFT,	Update user-data after-image if a UDWRITE is too expensive.	chunk	Decimal
UDUPAFT_LT		page within chunk	Decimal
		offset within page	Decimal
		data length	Decimal
UDUPBEF,	Update user-data beforeimage if a UDWRITE is too expensive.	chunk	Decimal
UDUPBEF_LT		page within chunk	Decimal
		offset within page	Decimal
		data length	Decimal
UDWRITE,	Update user data (difference image).	chunk	Decimal
UDWRITE_LT		page within chunk	Decimal
		offset within page	Decimal

Record Subtype	Action	Additional Columns	Format
		length before write	Decimal
		length after write	Decimal
		number of different image pieces	Decimal

For an example of smart-large-object records in **onlog** output, see smart-large-object log records in the chapter on what is the logical log in the *IBM® Informix® Administrator's Guide*.

Figure 1 shows an example of smart-large-object records in **onlog** output. The first two records show that an extent was freed. The next group of records, flanked by BEGIN and COMMIT, shows the allocation of storage and creation of the smart large objects.

Figure 1. Smart-Large-Object Records in onlog Output

```
addr    len   type    xid       id  link     subtype   specific-info

Administrative Utilities

- Overview of Utilities
  The Informix database server utilities allow you to perform administrative tasks directly from the command line.
- The finderr utility
  Use the **finderr** utility to view additional information on Informix error messages. On UNIX and Linux platforms, the information appears on the command line. On Windows platforms, the information appears in the Error Messages program.
- The genoncfg Utility
  Use the **genoncfg** utility to expedite the process of customizing the default Informix configuration file (**onconfig.std**) to the host environment and your planned usage of a database server instance.
- The oncheck Utility
  Use the **oncheck** utility to check specified disk structures for inconsistencies, repair inconsistent index structures, and display information about disk structures.
- The onclean utility
  Use the **onclean** utility to force a shut down of the database server when normal shut down with the **onmode** utility fails or when you cannot restart the server. The **onclean** utility attempts to clean up shared memory, semaphores, and stops database server virtual processes.
- The oncmsm utility
  Use the **oncmsm** utility to start or shut down a Connection Manager, load a new configuration file into a Connection Manager to modify the Connection Manager's settings, or update the format of a configuration file.
- The onconfig_diff utility
  Use the **onconfig_diff** utility to compare two onconfig files.
- The ondblog utility
  Use the **ondblog** utility to change the logging mode for one or more databases.
- The oninit utility
  The **oninit** utility starts the database server.
- The onkstash Utility
  Use the **onkstash** utility to create a password stash file for an existing PKCS#12 keystore.
- The onkstore Utility
- The onlog utility
  The **onlog** utility displays the contents of a logical-log file, either on disk or on backup.
- The onmode utility
  Use the **onmode** utility to change the database server operating mode and perform various other operations on shared memory, sessions, transactions, parameters, and segments.
- The onparams Utility
  Use the **onparams** utility to add or drop a logical-log file, change physical-log parameters, and add a new buffer pool.
- The onpassword utility
  Use the **onpassword** utility to encrypt and decrypt a password file. Connection Manager and Enterprise Replication utilities require a password file to connect to database servers over an untrusted network.
- The ifxclone utility
  You use the **ifxclone** utility to create a server clone from a snapshot of an existing database server.
- The onspaces utility
  Use the **onspaces** utility to manage the storage spaces in your database.
- The onstat utility
  The **onstat** utility reads shared-memory structures and provides statistics about the database server at the time that the command runs.

Overview of Utilities

The Informix® database server utilities allow you to perform administrative tasks directly from the command line.

For a complete list of server utilities, see Informix administrative utilities and applications.

The database server utilities support multibyte command-line arguments. For a complete list of the utilities that support multibyte command-line arguments, see the Locale-specific support for utilities.

The database server must be online before you execute a utility, with the following exceptions:

- **oninit**
- Some **onlog** options
- Some **oncheck** options

Note: When using utilities, do not use the UNIX command `CTRL-C` to send an interrupt signal to a process because it might produce an error.

- Obtaining utility version information
  Use the **-V** and **-version** options of many Informix command-line utilities to obtain version, primarily for debugging.
- Setting local environment variables for utilities
  On UNIX operating systems, you can start certain utilities without setting local environment variables in your shell environment. You can set local environment variables in the onconfig file. When you run the command to start the utility, use the **-FILE** option to point to the onconfig file.

Obtaining utility version information

Use the **-V** and **-version** options of many Informix® command-line utilities to obtain version, primarily for debugging.

The **-V** option displays the software version number and the serial number.

The **-version** option extends the **-V** option to display additional information about the build operation system, build number, and build date.

```
>>-utility--+-utility specific options-+----------------------><
            +- -V---------------------+
            '- -version----------------'
```

The **-V** and **-version** options cannot be used with any other utility options. For example, the **onstat -version** command might display the following output.

```
onstat -version
```

```
        Program:          onstat
    Build Version:    11.70.FC1
    Build Host:       connla
    Build OS:         SunOS 5.6
    Build Number:     009
    Build Date:       Sat Nov 20 03:38:27 CDT 2011
    GLS Version:      glslib-4.50.xC2
```

The **onstat -V** command might display the following information:

```
IBM Informix Version 11.70.FC1   Software Serial Number
 RDS#N000000
```

Setting local environment variables for utilities

On UNIX operating systems, you can start certain utilities without setting local environment variables in your shell environment. You can set local environment variables in the onconfig file. When you run the command to start the utility, use the **-FILE** option to point to the onconfig file.

Before you begin, ensure that these prerequisites are met:

- The path to the executable program for the utility is part of the existing shell environment.
- If you want to run commands on a remote computer, a remote shell utility such as SSH is configured.

1. Add values for one or more environment variables to the onconfig file. Use the following format for each directive: #$*variable_name value*
2. When you run the command to start the utility, use the **-FILE** option to specify the full or relative path to the onconfig file. Review the syntax, usage, and examples in the reference information for the **-FILE** option.

The utility reads and sets the environment variables that are specified in the onconfig file, and those values take precedence over values that are set in the local shell environment.

Database server files
The -FILE option

The finderr utility

Use the **finderr** utility to view additional information on Informix® error messages. On UNIX and Linux platforms, the information appears on the command line. On Windows platforms, the information appears in the Error Messages program.

Syntax

```
            .- - .
>>-finderr--+----+--error_number------------------------------><
            '- + '
```

Table 1. finderr element

Element	Purpose	Key Considerations
error_number	The error message number for which to provide additional information	**On UNIX or Linux:** If you do not include a minus sign (-) or plus sign (+) and both a positive and a negative version of the error message exists, the negative version of the message is displayed. To display the information about an error message number that is positive, preface the error number with a plus sign. **On Windows:** If you do not include a minus sign or plus sign and both a positive and a negative version of the error message exists, you must choose which message you want to view in the Error Messages program.

Usage

Error messages that are printed in the message log include a message number and a short message description. Use the message number with the **finderr** command to look up a more detailed description of the cause of the error and possible user actions to correct or prevent the error.

On Windows, you can open the Error Messages program directly by choosing Error Messages from the database server program group.

Examples

The following command on a UNIX or Linux platform displays information about the error message -201:

```
finderr 201

-201     A syntax error has occurred.

This general error message indicates mistakes in the form of an SQL
statement. Look for missing or extra punctuation (such as missing or
extra commas, omission of parentheses around a subquery, and so on),
keywords misspelled (such as VALEUS for VALUES), keywords misused (such
as SET in an INSERT statement or INTO in a subquery), keywords out of
sequence (such as a condition of "value IS NOT" instead of "NOT value
IS"), or a reserved word used as an identifier.

Database servers that provide full NIST compliance do not reserve any
words; queries that work with these database servers might fail and
return error -201 when they are used with earlier versions of IBM Informix
database servers.

The cause of this error might be an attempt to use round-robin syntax with
CREATE INDEX or ALTER FRAGMENT INIT on an index. You cannot use round-robin
indexes.

The error may also occur if an SQL statement uses double quotation marks
around input strings and the environment variable DELIMIDENT is set.
If DELIMIDENT is set, strings that are surrounded by double quotation
marks are regarded as SQL identifiers rather than string literals. For
more information on the usage of DELIMIDENT, see the IBM Informix Guide to
SQL: Reference.
```

The following command displays information about the error message 100, which corresponds to the SQLCODE value of 100:

```
finderr +100

100     No matching records found.

The database server did not find any more data. This message is an ANSI-
standard SQLCODE value. If you attempted to select or fetch data, you
encountered the end of the data, or no data matched the criteria in the
WHERE clause. Check for an empty table. Use this SQLCODE value to determine
when a statement reaches the end of the data. For more information, see the
discussion of SQLCODE in the IBM Informix ESQL/C Programmer's Manual. The
database server can return this SQLCODE value to a running program.
For the High-Performance Loader (HPL), this message can indicate that the
map might be from a project other than the default project. Use the -p option
in the onpload command line to provide a project name for mappings.
```

The genoncfg Utility

Use the **genoncfg** utility to expedite the process of customizing the default Informix® configuration file (**onconfig.std**) to the host environment and your planned usage of a database server instance.

Syntax

```
>>-genoncfg--+-input_file--+-------------+-+-------------------><
             |             '-informixdir-' |
             +- -h-------------------------+
             +- -V-------------------------+
             '- -version-------------------'
```

Element	Purpose	Key Considerations
input_file	Name of the input file containing your parameter settings.	
informixdir	Path to the Informix installation that you want to configure.	You can omit the installation path if the **INFORMIXDIR** environment variable is set. If the **INFORMIXDIR** variable is already set and you enter an installation path on the command line, the utility runs with the command-line path.
-h	Help information about the **genoncfg** utility.	
-V	Displays short version information and exits the command-line utility.	
-version	Displays extended version information and exits the command-line utility.	

Usage

Log in to the host computer as root or user **informix** before you run this utility.

You must set parameters that are valid for your host environment in an input file before you can successfully run the **genoncfg** utility. For all environments, the parameter `disk` is required in the input file. You can also enter directives in the input file. The directives are not required to run the utility, but they can be helpful in some circumstances.

The utility does not read or modify any existing configuration file. If you have a pre-existing ONCONFIG file in the host environment, none of its parameter values are changed when you run the utility. Therefore, you can review the recommended configuration settings before you put them in effect on a database server instance.

To use the genoncfg utility:

1. Create the input file containing your values for the parameters that the **genoncfg** utility processes with a text editor.
2. Run the utility with your input file. The configuration file (named **onconfig**) is generated and saved in the working directory.
3. *Optional:* Rename the generated configuration file.
4. If you want to run a database server instance with the generated configuration file, copy the file to `$INFORMIXDIR/etc` and update the **ONCONFIG** environment variable accordingly.

Input File for the genoncfg Utility

Use the input file to specify the following information about the database server instance:

- number of anticipated online transaction processing (OLTP) connections
- number of anticipated decision-support systems (DSS) connections
- disk space
- CPU utilization
- network connection settings
- recovery time

The input file is an ASCII text file. There is no required order for the parameters. The following is an example of an input file:

```
cpus 1
memory 1024 m
connection name demo_on onsoctcp 9088
servernum 1
oltp_connections 10
dss_connections 2
disk /opt/IBM/informix/demo/server/online_root 0 k 300 m
directive one_crit
directive debug
```

Table 1. Parameters of the Input File for the **genoncfg** Utility

Parameter	Description

Parameter	Description
connection	Server connection parameters: • `name` or `alias`, depending on whether the connection functions with a specific server name (the DBSERVERNAME parameter of the configuration file) or with an alternative server name (using the DBSERVERALIASES parameter of the configuration file) • name for the connection • type of server connection (equivalent to NETTYPE in the configuration file) • port number for the service Example: `connection name demo_on onsoctcp 9088`
cpus	Number of central processing units (CPUs) to allocate the instance. Example: `cpus 1`
directive	Directives that can be used with the **genoncfg** utility. • one_crit: Configures the database server to store physical logs, logical logs, and data in the root dbspace only. • debug: Displays information in real time about the host environment and actions done on the configuration file. Example: `directive one_crit` This information can be helpful in troubleshooting problems with database server configuration. One scenario is that the debug directive can result in saving time. In this scenario, you read the displayed information and notice that the utility is creating an onconfig file that you do not want or that will not function. You stop the utility while it is still running, adjust the input file settings, and then rerun the utility with the modified input file.
disk	Disk storage space settings for the instance: • location of the root dbspace • size of offset, in megabytes (m) or kilobytes (k) • size of root dbspace, in megabytes (m) or kilobytes (k) Example: UNIX: `/opt/IBM/dbspace/rootdbs` Windows: `d:\INFXDATA\rootdbs` Important: If you enter a path location that is the root dbspace of a working instance, the instance is overwritten and made unusable.
dss_connections	Estimated number of decision-support systems (DSS) connections to the instance. For example, a query client or other application that obtains result sets for business intelligence can be a DSS connection. Example: `dss_connections 2`
memory	Amount of memory, in megabytes (m), for the instance. Example: `memory 1024 m`
oltp_connections	Estimated number of online transaction processing (OLTP) connections to the instance. Typically, an application that modifies the state of databases in the instance is an OLTP connection. Example: `oltp_connections 10`
rto_server_restart	Specifies the amount of time, in seconds, that the database server has to recover from a problem after you restart Informix and bring it into online or quiescent mode. The value can be set either to 0 to disable the configuration parameter or to a value between 60 and 1800 to enable the parameter and indicate the number of seconds. Example: `rto_server_restart 100` specifies the recovery time objective as 100 seconds.
servernum	Unique ID of the database server instance. Example: `servernum 1`

Related tasks:
Modifying the onconfig file

The oncheck Utility

Use the **oncheck** utility to check specified disk structures for inconsistencies, repair inconsistent index structures, and display information about disk structures.

The **oncheck** utility requires sort space when examining an index. The amount of sort space required is the same as that needed to build the index. For information about calculating the amount of temporary space needed, see Estimating temporary space for index builds. If you receive the error "`no free disk space for sort`," you must estimate the amount of temporary space needed and make that space available.

You can use SQL administration API commands that are equivalent to some **oncheck** commands.

- oncheck Check-and-Repair
  The **oncheck** utility repairs disk structures.
- oncheck utility syntax
  The **oncheck** utility checks specified disk structures for inconsistencies, repairs inconsistent index structures, and displays information about disk structures.
- oncheck -cc and-pc: Check system catalog tables
  The **-cc** option checks system catalog tables for information about database tables, columns, indexes, views, constraints, stored procedures, and privileges.
- oncheck -cd and oncheck -cD commands: Check pages
  Use the **oncheck -cd** and **oncheck -cD** commands to check each page for consistency. Use the **oncheck -cd -y** or **oncheck -cD -y** command to repair inconsistencies.
- oncheck -ce, -pe: Check the chunk-free list
- oncheck -ci and -cI: Check index node links
  Use the **oncheck -ci** and **oncheck -cI** commands to check the ordering of key values and the consistency of horizontal and vertical node links for all indexes associated with the specified table.
- oncheck -cr and -cR: Check reserved pages
- oncheck -cs, -cS, -ps, -pS: Check and display sbspaces
- oncheck -pB: Display blobspace statistics

- oncheck -pd and pD: Display rows in hexadecimal format
- oncheck -pk, -pK, -pl, -pL: Display index information
- oncheck -pp and -pP: Display the contents of a logical page
- oncheck -pr and pR: Display reserved-page information
  The -pr option performs the same checks as **oncheck -cr** command and displays the reserved-page information.
- oncheck -pt and -pT: Display tblspaces for a Table or Fragment
  The **oncheck -pt** and **oncheck -pT** options print a tblspace report for a specific table or fragment. The only difference between these options is that **oncheck -pT** prints more information, including some index-specific information.
- Turn On Locking with -x
- Send Special Arguments to the Access Method with -u
- Return Codes on Exit

oncheck Check-and-Repair

The **oncheck** utility repairs disk structures.

The **oncheck** utility can repair the following types of disk structures:

- Partition page statistics
- Bitmap pages
- Partition blobpages
- Blobspace blobpages
- Indexes
- Sbspace pages
- Metadata partitions for sbspaces

If **oncheck** detects inconsistencies in other structures, messages alert you to these inconsistencies, but **oncheck** cannot resolve the problem. For more information, see the chapter on consistency checking in the *IBM® Informix® Administrator's Guide* and Disk Structures and Storage.

- What Does Each Option Do?
  The **oncheck** options fall into three categories: check, repair, and display.
- Using the -y Option to Perform Repairs
  Use the **-y** option to instruct **oncheck** to perform repairs automatically.
- Repairing Indexes in Sbspaces and External Spaces
  The **oncheck** utility can repair an index in an sbspace or external space if the index is created using an access method that supports the **oncheck -y** option.
- Locking and oncheck
  The **oncheck** utility places a shared lock on a table, so no other users can perform updates, inserts, or deletes until the check has completed.

What Does Each Option Do?

The **oncheck** options fall into three categories: check, repair, and display.

The display or print options (those prefixed with the letter **p**) are identical in function to the **-c** options, except that the **-p** options display additional information about the data that is being checked as the **oncheck** utility executes. You cannot combine **oncheck** option flags except as the following paragraphs describe.

In general, the **-c** options check for consistency and display a message on the screen only if they find an error or inconsistency.

Any user can execute the check options. On UNIX platforms, you must be user **informix** or **root** to display database data or initiate repair options. On Windows, you must be a member of the **Informix-Admin** group to display database data or initiate repair options.

Table 1 associates **oncheck** options with their function. It also shows the SQL administration API *command* strings that are equivalent to the **oncheck -c** options.

Table 1. oncheck Options and Their Function

Object	**Check**	**SQL administration API *command* string**	**Repair**	**Display**
Blobspace simple large objects				**-pB**
System catalog tables	**-cc**			**-pc**
Data rows, no simple large objects or smart large objects	**-cd**			**-pd**
Data rows, simple large objects but no smart large objects	**-cD**			**-pD**
Table with a user-defined access method	**-cd, -cD**	CHECK DATA		
Chunks and extents	**-ce**	CHECK EXTENTS		**-pe**
Index (key values)	**-ci, -cix**		**-ci -y -pk -y, -pkx -y**	**-pk**
Index (keys plus rowids)	**-cI, -cIx**		**-cI -y -pK -y, -pKx -y**	**-pK**
Index with a user-defined access method	**-ci, -cI**			
Index (leaf key values)			**-pl -y, -plx -y**	**-pl**
Index (leaf keys plus rowids)			**-pL -y, -pLx -y**	**-pL**

Object	Check	SQL administration API *command* string	Repair	Display
Pages (by table or fragment)				**-pp**
Pages (by chunk)				**-pP**
Root reserved pages	**-cr, -cR**			**-pr, -pR**
Metadata for smart large objects	**-cs, -cS**			**-ps, -pS**
Space usage (by table or fragment)		CHECK PARTITION PRINT PARTITION		**-pt**
Space usage (by table, with indexes)				**-pT**

Using the -y Option to Perform Repairs

Use the **-y** option to instruct **oncheck** to perform repairs automatically.

If you do not use the **-y** option, **oncheck** prompts you when it encounters an inconsistency and allows you to request a repair. If you specify option **-n**, **oncheck** does not prompt you because this option instructs **oncheck** to not perform repairs.

The following examples show automatic repair commands for the **oncheck** utility:

```
oncheck -cd -y
oncheck -cD -y
oncheck -ci -y
oncheck -cI -y
```

Repairing Indexes in Sbspaces and External Spaces

The **oncheck** utility can repair an index in an sbspace or external space if the index is created using an access method that supports the **oncheck -y** option.

Although the **oncheck** utility does not repair fragmented indexes, user-defined access methods can repair them. For more information about the **oncheck** options that access methods support, see the *IBM® Informix® DataBlade API Programmer's Guide* or the *IBM Informix Virtual-Index Interface Programmer's Guide*.

Locking and oncheck

The **oncheck** utility places a shared lock on a table, so no other users can perform updates, inserts, or deletes until the check has completed.

The **oncheck** utility places a shared lock on a table during the following operations:

- When it checks data
- When it checks indexes (with **-ci**, **-cI**, **-pk**, **-pK**, **-pl**, or **-pL**) and the table uses page locking
- When you specify the **-x** option with **-ci**, **-cI**, **-pk**, **-pK**, **-pl**, or **-pL** and the table uses row locking

If the table does not use page locking, the database server does not place a shared lock on the table when you check an index with the **oncheck -ci**, **-cI**, **-pk**, **-pK**, **-pl**, or **-pL** options. When no shared lock is on the table during an index check, other users can update rows during the check.

By not placing a shared lock on tables using row locks during index checks, the **oncheck** utility cannot be as accurate in the index check. For absolute assurance of a complete index check, you can execute **oncheck** with the **-x** option. With the **-x** option, **oncheck** places a shared lock on the table, and no other users can perform updates, inserts, or deletes until the check has completed.

The **oncheck** utility returns unreliable results when run on secondary servers in a high-availability cluster.

For more information about the **-x** option, refer to Turn On Locking with -x. For information on shared locks and intent shared locks, see the *IBM® Informix® Performance Guide*.

The **oncheck** utility places a shared lock on system catalog tables when they are checked. It places an exclusive lock on a table when it executes repair options.

oncheck utility syntax

The **oncheck** utility checks specified disk structures for inconsistencies, repairs inconsistent index structures, and displays information about disk structures.

```
>>-oncheck--+------------------------+------------------------>
```

Notes:

1. See The -FILE option.

Element	Purpose	Key Considerations
-cc	Checks system catalog tables for the specified database	See oncheck -cc and-pc: Check system catalog tables.
-cd	Reads all pages except simple large objects from the tblspace for the specified database, table, or fragment and checks each page for consistency Also checks tables that use a user-defined access method	Does not check simple or smart large objects. See oncheck -cd and oncheck -cD commands: Check pages.
-cD	Same as **-cd** but also reads the header of each blobpage and checks it for consistency	Checks simple large objects but not smart large objects. See oncheck -cd and oncheck -cD commands: Check pages .
-ce	Checks each chunk-free list and corresponding free space and each tblspace extent. Also checks smart-large-object extents and sbspace metadata	The **oncheck** process verifies that the extents on disk correspond to the current control information that describes them. See oncheck -ce, -pe: Check the chunk-free list. For background information, see Next-Extent Allocation.
-ci	Checks the ordering of key values and the consistency of horizontal and vertical node links for all indexes associated with the specified table Also checks indexes that use a user-defined access method	See oncheck -ci and -cI: Check index node links.
-cI	Same as **-ci** but also checks that the key value tied to a rowid in an index is the same as the key value in the row	See oncheck -ci and -cI: Check index node links.
-cr	Checks each of the root dbspace reserved pages for several conditions	See oncheck -cr and -cR: Check reserved pages.
-cR	Checks the root dbspace reserved pages, physical-log pages, and logical-log pages	See oncheck -cr and -cR: Check reserved pages
-cs	Checks smart large object and sbspace metadata for an sbspace	See oncheck -cs, -cS, -ps, -pS: Check and display sbspaces.
-cS	Checks smart large object and sbspace metadata for an sbspace as well as extents	See oncheck -cs, -cS, -ps, -pS: Check and display sbspaces.

Element	Purpose	Key Considerations
sbspace	Indicates optional sbspace name If not supplied, all sbspaces are checked.	None.
-n	Indicates that no index repair should be performed, even if errors are detected	Use with the index repair options (**-ci**, **-cI**, **-pk**, **-pK**, **-pl**, and **-pL**).
-pB	Displays statistics that describe the average fullness of blobspace blobpages in a specified table	These statistics provide a measure of storage efficiency for individual simple large objects in a database or table. If a table or fragment is not specified, statistics are displayed for the entire database. See oncheck -pB: Display blobspace statistics. For information about optimizing blobspace blobpage size, see the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-pc	Same as **-cc** but also displays the system catalog information as it checks the system catalog tables, including extent use for each table	None.
-pd	Displays rows in hexadecimal format	See oncheck -pd and pD: Display rows in hexadecimal format.
-pD	Displays rows in hexadecimal format and simple-large-object values stored in the tblspace or header information for smart large objects stored in an sbspace sbpage and simple large objects stored in a blobspace blobpage	See oncheck -pd and pD: Display rows in hexadecimal format.
-pe	Same as **-ce** but also displays the chunk and tblspace extent information as it checks the chunk free list, the corresponding free space, and each tblspace extent	See oncheck -ce, -pe: Check the chunk-free list.
-pk	Same as **-ci** but also displays the key values for all indexes on the specified table as it checks them	See oncheck -pk, -pK, -pI, -pL: Display index information.
-pK	Same as **-cI** but also displays the key values and rowids as it checks them	See oncheck -pk, -pK, -pI, -pL: Display index information.
-pl	Same as **-ci** but also displays the key values. Only leaf-node index pages are checked	See oncheck -pk, -pK, -pI, -pL: Display index information.
-pL	Same as **-cI** but also displays the key values and rowids for leaf-node index pages only	See oncheck -pk, -pK, -pI, -pL: Display index information.
-pp	Displays contents of a logical page	See oncheck -pp and -pP: Display the contents of a logical page.
-pP	Same as **-pp** but requires a chunk number and logical page number or internal rowid as input	See oncheck -pp and -pP: Display the contents of a logical page.
-pr	Same as **-cr** but also displays the reserved-page information as it checks the reserved pages	See oncheck -pr and pR: Display reserved-page information.
-pR	Same as **-cR** but also displays the information for the reserved pages, physical-log pages, and logical-log pages	See oncheck -pr and pR: Display reserved-page information.
-ps	Checks and displays smart-large-object and sbspace metadata for an sbspace	See oncheck -cs, -cS, -ps, -pS: Check and display sbspaces.
-pS	Checks and displays smart-large-object and sbspace metadata. Lists extents and header information for individual smart large objects	See oncheck -cs, -cS, -ps, -pS: Check and display sbspaces.
-pt	Displays tblspace information for a table or fragment	See oncheck -pt and -pT: Display tblspaces for a Table or Fragment.
-pT	Same as **-pt** but also displays index-specific information and page-allocation information by page type (for dbspaces)	See oncheck -pt and -pT: Display tblspaces for a Table or Fragment.
-q	Suppresses all checking and validation message	None.
-x	Places a shared lock on the table when you check and print an index	Use with the **-ci**, **-cI**, **-pk**, **-pK**, **-pl**, or **-pL** options. For complete information, see Turn On Locking with -x.
-y	Repairs indexes when errors are detected	None.
-V	Displays the software version number and the serial number	See Obtaining utility version information.
-version	Displays the build version, host, OS, number and date, as well as the GLS version	See Obtaining utility version information.
chunknum	Specifies a decimal value that you use to indicate a particular chunk	Value must be an unsigned integer greater than 0. Chunk must exist. Execute the **-pe** option to learn which chunk numbers are associated with specific dbspaces, blobspaces or sbspaces.
database	Specifies the name of a database that you want to check for consistency	Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*.
db1	Specifies the local database that contains a data type that you want to check	Optionally specify the local database server name using the format **db1@server1**.
db2	Specifies the remote database that contains a data type that you want to check	Optionally specify the remote database server name using the format **db2@server2**.

Element	Purpose	Key Considerations
frag_dbs	Specifies the name of a dbspace that contains a fragment you want to check for consistency	Dbspace must exist and contain the fragment that you want to check for consistency. Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*.
index_name	Specifies the name of the index that you want to check for consistency	Index must exist on table and in database specified. Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*.
logical pagenum	Specifies an integer value that you use to indicate a particular page in a tblspace	Value must be an unsigned integer between 0 and 16,777,215, inclusive. Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier.
object	Specifies the name of the DataBlade, cast, operator , user-defined data type, or UDR that you want to check	If you do not specify an object name, the database server compares all objects of the same type with the same name and owner.
owner	Specifies the owner of a table	You must specify the current owner of the table. Syntax must conform to the Owner Name segment; for more information, see *IBM Informix Guide to SQL: Syntax*.
pagenum	Indicates the page number of the sbspace metadata portion to check and display	None.
partnum	Identifies the sbspace metadata partition to check and display	None.
rowid	Identifies the rowid of the row whose contents you want to display. The rowid is displayed as part of **oncheck -pD** output	Value must be an unsigned integer between 0 and 4,277,659,295, inclusive. Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier.
sbspace	Specifies the name of the sbspace that you want to check for consistency	None.
server	Specifies the database server name	If you omit the database server name, **oncheck** uses the name that INFORMIXSERVER specifies.
table	Specifies the name of the table that you want to check for consistency	Table exists when you execute the utility. Syntax must conform to the Table Name segment; for more information, see *IBM Informix Guide to SQL: Syntax*.
tblspacenum	Identifies the tblspace whose contents you want to display	Value must be an unsigned integer between 0 and 208,666,624, inclusive. Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier.

oncheck -cc and-pc: Check system catalog tables

The **-cc** option checks system catalog tables for information about database tables, columns, indexes, views, constraints, stored procedures, and privileges.

```
Syntax:

>>-oncheck----+- -cc-+--database-------------------------------><
              '- -pc-'
```

The **oncheck -cc** command checks the following tables:

- **systables**
- **syscolumns**
- **sysindices**
- **systabauth**
- **syscolauth**
- **sysdepend**
- **syssyntable**
- **sysviews**
- **sysconstraints**
- **sysams**

If you do not specify a database name in the **oncheck -cc**, the command checks the listed system catalog tables for all databases.

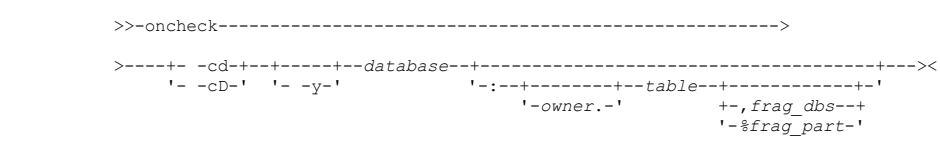
The **-pc** option performs the same checks on system catalog tables and also displays the system catalog information, including the physical address, type of locking used, row size, number of keys, extent use, the number of pages allocated and used, tblspace partnum, and index use for each table.

Before you execute **oncheck -cc** or **oncheck -pc**, execute the SQL statement UPDATE STATISTICS to ensure that an accurate check occurs. To check a table, **oncheck** compares each system catalog table to its corresponding entry in the tblspace.

oncheck -cd and oncheck -cD commands: Check pages

Use the **oncheck -cd** and **oncheck -cD** commands to check each page for consistency. Use the **oncheck -cd -y** or **oncheck -cD -y** command to repair inconsistencies.

Syntax:



The **oncheck -cd** command reads all pages, except for blobpages and sbpages, from the tblspace for the specified database, table, fragment, or multiple fragments (fragparts), and checks each page for consistency. This command compares entries in the bitmap page to the pages to verify mapping.

The **oncheck -cD** command performs the same checks as the **oncheck -cd** command, and also checks the header of each blobpage for consistency. The **oncheck -cD** command does not compare the beginning time stamps stored in the header with the ending time stamps stored at the end of a blobpage. Use the **oncheck -cD -y** command to clean up orphaned simple large objects in blobspaces, which can occur after a rollback across several log files.

If the database contains fragmented tables, but no fragment is specified, the **oncheck -cd** command checks all fragments in the table. If you do not specify a table, the command checks all of the tables in the database. By comparison, the **oncheck -pd** command displays a hexadecimal dump of specified pages but does not check for consistency.

For both the **oncheck -cd** and **oncheck -cD** commands, the **oncheck** utility locks each table as it checks the indexes for the table. To repair the pages, use **oncheck -cd -y** or **oncheck -cD -y**.

If tables are fragmented on multiple partitions in the same dbspace, the **oncheck -cd** and **oncheck -cD** commands show the partition names. The following example shows typical output for a table that has fragments in multiple partitions in the same dbspace:

```
TBLspace data check for multipart:informix.t1
              Table fragment partition part_1 in DBspace dbs1
              Table fragment partition part_2 in DBspace dbs1
              Table fragment partition part_3 in DBspace dbs1
              Table fragment partition part_4 in DBspace dbs1
              Table fragment partition part_5 in DBspace dbs1
```

When you use the **oncheck -cd** or **oncheck -cD** command, you can specify either the *frag_dbs* or the *%frag_dbs* option but not both:

- When you use the *frag_dbs* option, the utility checks all fragments in the dbspace `frag_dbs`.
- When you use the *%frag_dbs* option, the utility checks only the fragment named *frag_part*, if the PARTITION syntax was used when the fragment or table was created.

While it is possible to fragment an index with the PARTITION syntax, it is not possible to limit an index check to just one fragment or partition. For example, you can specify **oncheck -cDI my_db:my_tab,data_dbs1** or **oncheck -cDI my_db:my_tab%part1**. The **D** (data) portion of the check is limited according to the specification, however the **I** (index) check is not limited.

Examples

The following example checks the data rows, including simple large objects and smart large objects, in the **catalog** table:

```
oncheck -cD superstores_demo:catalog
```

If you specify a single fragment, the **oncheck** utility displays a single header for that fragment. For fragmented tables, one header is displayed for each fragment:

```
TBLspace data check for stores_demo:informix.tab1
 Table fragment in DBspace db1
```

Messages

If the **oncheck** utility finds no inconsistencies, a header displays for each table that the utility. For example:

```
TBLSPACE data check for stores_demo:informix.customer
```

If the **oncheck** utility finds an inconsistency, a message displays. For example:

```
BAD PAGE 2:28: pg_addr 2:28 != bp-> bf_pagenum 2:69
```

The physical address `2:28` represents page 28 of chunk number 2.

If an index that uses an access method provided by a DataBlade module cannot find the access method, you receive the following message:

```
-9845 Access method access_method_name does not exist in database.
Ensure that the DataBlade installation was successful.
```

Reference

To monitor blobspace blobpages, see oncheck -pB: Display blobspace statistics.

Related reference:
check data argument: Check data consistency (SQL administration API)

oncheck -ce, -pe: Check the chunk-free list

Syntax:

```
>>-oncheck----+- -ce-+-----------------------------------------><
              '- -pe-'
```

The **-ce** option checks each chunk-free list and corresponding free space and each tblspace extent. For more information, refer to Next-Extent Allocation and Structure of the Chunk Free-List Page, respectively. The **oncheck** process verifies that the extents on disk correspond to the current control information that describes them.

The **-pe** option performs the same checks and also displays the chunk and tblspace extent information during the check. The **-ce** and **-pe** options also check blobspaces, smart-large-object extents, and user-data and metadata information in sbspace chunks.

For information about using **oncheck -ce** and **-pe**, see managing disk space in the *IBM® Informix® Administrator's Guide*.

Use CHECK EXTENTS as the SQL administration API *command* string for **oncheck -ce**.

Related reference:
check extents argument: Check extent consistency (SQL administration API)

oncheck -ci and -cI: Check index node links

Use the **oncheck -ci** and **oncheck -cI** commands to check the ordering of key values and the consistency of horizontal and vertical node links for all indexes associated with the specified table.

The **oncheck -cI** command also checks that the key value tied to a rowid in an index is the same as the key value in the row. The **-cI** option does not cross-check data on a functional index.

Syntax:

```
>>-oncheck------------------------------------------------------>

>----+- -ci +--database--+-------------------------------------+--><
     '- -cI '            '-:--+--------+--table--+----------+-'
                              '-owner.-'         '- #index -'
```

If you do not specify an index, the option checks all indexes. If you do not specify a table, the option checks all tables in the database.

The same **-ci** repair options are available with **-cI**. If **oncheck -ci** or **oncheck -cI** detects inconsistencies, it prompts you for confirmation to repair the problem index. If you specify the **-y** (yes) option, indexes are automatically repaired. If you specify the **-n** (no) option, the problem is reported but not repaired; no prompting occurs.

If **oncheck** does not find inconsistencies, the following message appears:

```
validating indexes......
```

The message displays the names of the indexes that **oncheck** is checking.

Note: Using **oncheck** to rebuild indexes can be time consuming. Processing is usually faster if you use the SQL statements DROP INDEX and CREATE INDEX to drop and re-create the index.
The following example checks all indexes on the **customer** table:

```
oncheck -cI -n stores_demo:customer
```

The following example checks the index **zip_ix** on the **customer** table:

```
oncheck -cI -n stores_demo:customer#zip_ix
```

If indexes are fragmented on multiple partitions in the same dbspace, the **oncheck -ci** and **oncheck -cI** commands show the partition names. The following example show typical output for an index that has fragments in multiple partitions in the same dbspace:

```
Validating indexes for multipart:informix.t1...
                Index idx_t1
                  Index  fragment partition part_1 in DBspace dbs1
                  Index  fragment partition part_2 in DBspace dbs1
                  Index  fragment partition part_3 in DBspace dbs1
                  Index  fragment partition part_4 in DBspace dbs1
                  Index  fragment partition part_5 in DBspace dbs1
```

By default, the database server does not place a shared lock on the table when you check an index with the **oncheck -ci** or **oncheck -cI** commands unless the table uses page locking. For absolute assurance of a complete index check, you can execute **oncheck -ci**or **oncheck -cI** with the **-x** option. With the **-x** option, **oncheck** places a shared lock on the table, and no other users can perform updates, inserts, or deletes until the check has completed. For more information about using **oncheck -ci** and **oncheck -cI** with the **-x** option, Turn On Locking with -x.

When you execute **oncheck** on an external index, the user-defined access method is responsible for checking and repairing an index. If an index that employs a user-defined access method cannot find the access method, the database server reports an error. The **oncheck** utility does not repair inconsistencies in external indexes. You should not use **oncheck -cI** on a table that contains more than one type of index.

The **oncheck** utility requires sort space when examining an index. The amount of sort space required is the same as that needed to build the index. For information about calculating the amount of temporary space needed, see Estimating temporary space for index builds. If you receive the error "`no free disk space for sort`," you must estimate the amount of temporary space needed and make that space available.

For more information about indexes, see Structure of B-Tree Index Pages.

oncheck -cr and -cR: Check reserved pages

Syntax:

```
>>-oncheck----+- -cr-+-----------------------------------------><
              '- -cR-'
```

The -cr option checks each of the root dbspace reserved pages as follows:

- It validates the contents of the ONCONFIG file with the PAGE_CONFIG reserved page.
- It ensures that all chunks can be opened, that chunks do not overlap, and that chunk sizes are correct.

The -cR option performs the same checking and validation, and also checks all logical-log and physical-log pages for consistency. The -cr option is considerably faster because it does not check the log-file pages.

If you have changed the value of a configuration parameter (either through **onparams**, **onmonitor**, **onspaces**, or by editing the configuration file), but you have not yet reinitialized shared memory, **oncheck -cr** and **oncheck -cR** detect the inconsistency and return an error message.

If **oncheck -cr** does not display any error messages after you execute it, you can assume that all three items in the preceding list were checked successfully.

For more information on reserved pages, see Reserved Pages.

Related reference:
oncheck -pr and pR: Display reserved-page information

oncheck -cs, -cS, -ps, -pS: Check and display sbspaces

Syntax:

```
>>-oncheck--+-+- -cs-+--+---------+------------------+--------><
            | '- -cS-'  '-sbspace-'                  |
            '-+- -ps-+--+--------------------------+-'
              '- -pS-'  '-sbspace--partnum--pagenum-'
```

The **-cs** option checks sbspaces. The **-ps** option checks sbspaces and extents.

The **-cS** option validates and displays metadata for an sbspace.

The **-ps** option checks sbspaces and extents. If you do not specify the sbspace name, these options check all sbspaces.

The **-pS** option validates and displays metadata for an sbspace and also lists extents and header information for smart large objects.

If you do not specify the sbspace name, all sbspaces will be checked. The following example checks and displays metadata for **test_sbspace**:

```
oncheck -ps test_sbspace
```

If you specify **rootdbs** as the sbspace name with the **-cs** or **-ps** options, **oncheck** checks the root dbspace.

For more information about using the **-cs, -cS, -ps,** and**-pS** options, see the *IBM® Informix® Administrator's Guide*.

oncheck -pB: Display blobspace statistics

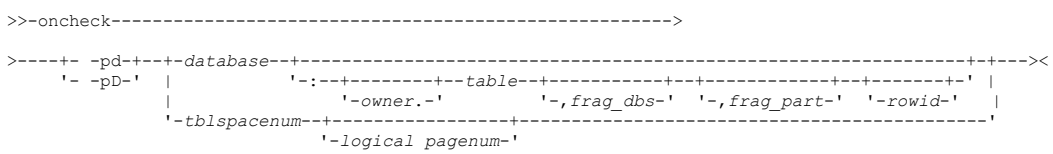
Syntax:

```
>>-oncheck---- -pB----database--+-------------------------------------+-><
                                '-:--+--------+--table--+-----------+-'
                                     '-owner.-'         '-,frag_dbs-'
```

The **-pB** option displays statistics that describe the average fullness of blobspace blobpages in a specified table. These statistics provide a measure of storage efficiency for individual simple large objects in a database or table. If you do not specify a table or fragment, the option displays statistics for the entire database. For more information, see optimizing blobspace blobpage size in the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*.

oncheck -pd and pD: Display rows in hexadecimal format

Syntax:



The **-pd** option takes a database, a table, a fragment, a fragment partition (fragpart), and a specific rowid or tblspace number and logical page number as input. In every case, **-pd** prints page-header information and displays the specified rows for the database object (database, table, fragment, internal rowid, or page number) that you specify in hexadecimal and ASCII format. No checks for consistency are performed.

Element	Purpose	Key Considerations
database	Specifies the name of a database that you want to check for consistency	Syntax must conform to the Identifier segment; see *IBM® Informix® Guide to SQL: Syntax*.
frag_dbs	Specifies the name of a dbspace that contains a fragment you want to check for consistency	Dbspace must exist and contain the fragment that you want to check for consistency. Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*.
frag_part	Specifies the fragment partition	For fragmented tables or an index that use expression-based or round-robin distribution schemes, you can create multiple partitions, which are collections of pages for a table or index, within a single dbspace. This partition is referred to as a *fragment partition* or *fragpart*.
logical pagenum	Specifies an integer value that you use to indicate a particular page in a tblspace	Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier. Value must be an unsigned integer between 0 and 16,777,215, inclusive.
owner	Specifies the owner of a table	You must specify the current owner of the table. Syntax must conform to the Owner Name segment; see *IBM Informix Guide to SQL: Syntax*.
rowid	Identifies the rowid of the row whose contents you want to display. The rowid is displayed as part of **oncheck -pD** output	Value must be an unsigned integer between 0 and 4,277,659,295, inclusive. Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier.
table	Specifies the name of the table that you want to check for consistency	Table exists when you execute the utility. Syntax must conform to the Table Name segment; see *IBM Informix Guide to SQL: Syntax*.
tblspacenum	Identifies the tblspace whose contents you want to display	Value must be an unsigned integer between 0 and 208,666,624, inclusive. Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier.

If you specify an internal rowid (expressed as a hexadecimal value), the rowid maps to a particular page, and all rows from that page are printed.

If you specify a logical page number (expressed as a decimal), all the rows of the tblspace number with the logical page number are printed.

If you specify a fragment, all the rows in the fragment are printed, with their rowids, forward pointers, and page type.

If you specify a table, all the rows in the table are printed, with their rowids, forward pointers, and page type.

If you specify a database, all the rows in all the tables in the database are printed. TEXT and BYTE column descriptors stored in the data row are printed, but TEXT and BYTE data itself is not.

The **-pD** option prints the same information as **-pd**. In addition, **-pD** prints TEXT and BYTE values stored in the tblspace or header information for simple large objects stored in a blobspace blobpage. The following example show different options for the **oncheck -pd** and **oncheck -pD** commands:

```
oncheck -pd stores_demo:customer,frgmnt1
oncheck -pd stores_demo:customer
oncheck -pD stores_demo:customer 0x101
```

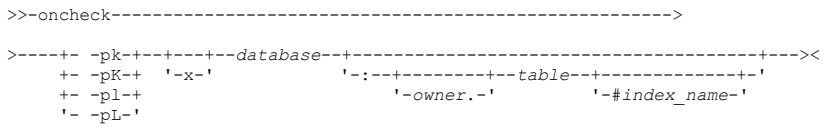
The following example shows a partial output of an **oncheck -pD** command:

```
oncheck -pD multipart:t1 :

TBLspace data check for multipart:informix.t1
                Table fragment partition part_1 in DBspace dbs1
page_type  rowid    length fwd_ptr
HOME       101      24     0
    0:  0  0  0  a 47 48 49 20 20 20 20 20 20 20 20 20    ....GHI
   16: 20 20 20 20 20 20 20 20
                                        ........
```

oncheck -pk, -pK, -pl, -pL: Display index information

Syntax:



The **-pk** option performs the same checks as the **-ci** option and in addition, displays the key values for all indexes on the specified table as it checks them.

The **-pK** option performs the same checks as the **-cI** option and in addition, displays the key values and rowids as it checks them.

The **-pl** option performs the same checks as the **-ci** option and displays the key values, but checks only leaf-node index pages. It ignores the root and branch-node pages.

The **-pL** option performs the same checks as the **-cI** option and displays the key values and rowids, but checks only leaf-node index pages. It ignores the root and branch-node pages.

Element	Purpose	Key Considerations
database	Specifies the name of a database that you want to check for consistency	Syntax must conform to the Identifier segment; see *IBM® Informix® Guide to SQL: Syntax*.
index_name	Specifies the name of the index that you want to check for consistency	Index must exist on table and in database specified. Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*.
owner	Specifies the owner of a table	You must specify the current owner of the table. Syntax must conform to the Owner Name segment; see *IBM Informix Guide to SQL: Syntax*.
table	Specifies the name of the table that you want to check for consistency	Table exists when you execute the utility. Syntax must conform to the Table Name segment; see *IBM Informix Guide to SQL: Syntax*.
-x	Places a shared lock on the table when you check and print an index	For complete information, see Turn On Locking with -x.

If any of the **oncheck** options detect inconsistencies, you are prompted for confirmation to repair the problem index. If you specify the **-y** (yes) option, indexes are automatically repaired. If you specify the **-n** (no) option, the problem is reported but not repaired; no prompting occurs.

The following example displays information about all indexes on the **customer** table:

```
oncheck -pl -n stores_demo:customer
```

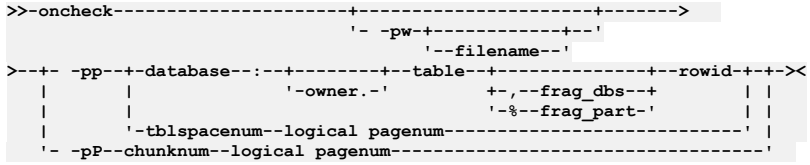
The following example displays information about the index **zip_ix**, which was created on the **customer** table:

```
oncheck -pl -n stores_demo:customer#zip_ix
```

By default, the database server does not place a shared lock on the table when you check an index with the **oncheck -pk, -pK, -pl,** or **-pL** options unless the table uses page locking. For absolute assurance of a complete index check, you can execute **oncheck –pk**, **oncheck -pK** , **oncheck -pl** , or **oncheck -pL** with the **-x** option. With the **-x** option, **oncheck** places a shared lock on the table, and no other users can perform updates, inserts, or deletes until the check has completed. For more information on using the **-x** option, Turn On Locking with -x.

For more information on **oncheck -ci**, see oncheck -ci and -cI: Check index node links. For more information index pages, see Structure of B-Tree Index Pages.

oncheck -pp and -pP: Display the contents of a logical page



Element	Purpose	Key Considerations
database	Specifies the name of a database that you want to check for consistency	Syntax must conform to the Identifier segment; see *IBM® Informix Guide to SQL: Syntax*.
chunknum	Specifies a decimal value that you use to indicate a particular chunk	Value must be an unsigned integer greater than 0. Chunk must exist.
frag_dbs	Specifies the name of a dbspace that contains a fragment you want to check for consistency	Dbspace must exist and contain the fragment that you want to check for consistency. Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*.
frag_part	Specifies the partition name of the fragment to be checked. This is useful in cases where more than one fragment of a table was created in the same dbspace.	For fragmented tables or an index that use expression-based or round-robin distribution schemes, you can create multiple partitions, which are collections of pages for a table or index, within a single dbspace. This partition is referred to as a *fragment partition* or *fragpart*.

Element	Purpose	Key Considerations
logical pagenum	Specifies an integer value that you use to indicate a particular page in a tblspace	Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier. Value must be an unsigned integer between 0 and 16,777,215, inclusive.
owner	Specifies the owner of a table	You must specify the current owner of the table. Syntax must conform to the Owner Name segment; see *IBM Informix Guide to SQL: Syntax.*
rowid	Identifies the rowid of the row whose contents you want to display. The rowid is displayed as part of **oncheck -pD** output	Value must be an unsigned integer between 0 and 4,277,659,295, inclusive. Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier.
table	Specifies the name of the table that you want to check for consistency	Table exists when you execute the utility. Syntax must conform to the Table Name segment; see *IBM Informix Guide to SQL: Syntax.*
tblspacenum	Identifies the tblspace whose contents you want to display	Value must be an unsigned integer between 0 and 208,666,624, inclusive. Value can be expressed as an unsigned integer or hexadecimal that begins with 0x identifier.

The **-pp** option has the following syntax variations:

Invocation	Explanation
oncheck -pp tblspc lpn <pages>	Displays the contents of a logical page using a tblspace number and logical page number. You can also specify an optional parameter specifying the number of pages to be printed.
oncheck -pp *tblspc lpn -h*	Displays only the header of a logical page using a tblspace number and logical page number.
oncheck -pp *database:table rowid*	Displays the contents of a logical page using a database name, table name, and the Informix® internal rowid. You can obtain this internal rowid with the **oncheck -pD** command. This internal rowid is not the serial rowid that is assigned in tables created with the CREATE TABLE tabname WITH ROWIDS statement. For more information, see Definition of Rowid

The page contents appear in ASCII format. The display also includes the number of slot-table entries on the page. The following example shows different invocations of the **oncheck -pp** command:

```
oncheck -pp stores_demo:orders 0x211  # database:owner.table,   # fragment rowid
oncheck -pp stores_demo:informix.customer,frag_dbspce1 0x211
oncheck -pp 0x100000a 25 # specify the tblspace number and # logical page number
```

The **-pP** option provides the following syntax variations:

Invocation	Explanation
oncheck -pP chunk# offset pages	Displays the contents of a logical page using a chunk number and an offset. You can also specify an optional parameter specifying the number of pages to be printed.
oncheck -pP *chunk# offset -h*	Displays only the header of a logical page using a chunk number and an offset.

Note: The output for chunk page displays both the `start` and the `length` fields in decimal format.
Note:
The -pw option is required only when the Storage space encryption feature is enabled and no stash file is in use. Supply an optional path to a file containing the keystore password, otherwise oncheck will prompt for a password before displaying the requested page(s).

The following example shows typical output using the **onstat -pP** command:

```
oncheck -pP 1 5 2
addr          stamp          nslots          flag       type          frptr       frcnt       next       prev
stamp          100005          250181          2          1000       ROOTRSV          320       1716       0
0       250181       slot       ptr       len       flg
...
addr       stamp          nslots          flag       type          frptr       frcnt       next       prev
stamp       100005    6       250182       2       1000       ROOTRSV       128       1908       0       0
250182       slot       ptr       len       flg       1       24       56       0
2       80       48         0
```

oncheck -pr and pR: Display reserved-page information

The -pr option performs the same checks as **oncheck -cr** command and displays the reserved-page information.

```
>>-oncheck----+- -pr-+---+----------------------+------------><
              '- -pR-'   '- -pw-+------------+--'
                                '--filename--'
```

The -pR option performs the same checks as the **oncheck -cR** command, displays the reserved-page information, and displays detailed information about logical-log and physical-log pages, including marking the start and end of the active physical-log pages.

The following example show output of the **oncheck -pr** command:

```
Validating IBM Informix Dynamic Server reserved pages

    Validating PAGE_PZERO...

    Identity                        IBM Informix Dynamic Ser
                                    ver Copyright 2001, 2016
```

```
                                  IBM Corporation
    Database system state          0
    Database system flags          0xc039
        64-bit server
        BigChunk page flags are not in use
        Encryption-at-rest is enabled using cipher 'aes192'
        The ROOT Dbspace is encrypted
    Page Size                      2048 (b)
    Date/Time created              05/12/2016 18:01:09
    Version number of creator      28
    UID of rootdbs creator         200
    Index Page Logging             OFF
    HA Disk Owner                  <null>
```

If you have changed the value of a configuration parameter, but you have not yet reinitialized shared memory, the **oncheck -pr** and **oncheck -pR** commands detect the inconsistency and return an error message.

Note:
The -pw option is required only when the Storage space encryption feature is enabled and no stash file is in use. Supply an optional path to a file containing the keystore password, otherwise oncheck will prompt for a password before displaying the requested page(s).

Related concepts:
Reserved Pages
Related reference:
oncheck -cr and -cR: Check reserved pages
DISK_ENCRYPTION configuration parameter

oncheck -pt and -pT: Display tblspaces for a Table or Fragment

The **oncheck -pt** and **oncheck -pT** options print a tblspace report for a specific table or fragment. The only difference between these options is that **oncheck -pT** prints more information, including some index-specific information.

Syntax

```
>>-oncheck-----------------------------------------------------><

>----+- -pt-+--database--+--------------------------------------+---><
     '- -pT-'            '-:--+--------+--table--+------------+-'
                              '-owner.-'         '-,frag_dbs-'
```

Table 1. Options of the oncheck -pt and oncheck -pT commands

Element	Purpose	Key Considerations
database	Specifies the name of a database that you want to check for consistency	Syntax must conform to the Identifier segment; see Identifier.
frag_dbs	Specifies the name of a dbspace that contains a fragment you want to check for consistency	The dbspace must exist and contain the fragment that you want to check for consistency. Syntax must conform to the Identifier segment; see Identifier.
owner	Specifies the owner of a table	You must specify the current owner of the table. Syntax must conform to the Owner Name segment; see Owner name.
table	Specifies the name of the table that you want to check for consistency	The table must exist. Syntax must conform to the Identifier segment; see Identifier.

The **-pt** option prints a tblspace report for the table or fragment with the specified name and database. If you do not specify a table, the option displays this information for all tables in the database. The report contains general allocation information, including the maximum row size, the number of keys, the number of extents, their sizes, the pages allocated and used per extent, the current serial value, and the date that the table was created. The **-pt** output prints the page size of the tblspace, the number of pages (allocated, used, and data) in terms of logical pages.

The **TBLspace Flags** field shows information about the tblspace configuration, including whether the tblspace is used for Enterprise Replication or time series data.

The **Extents** fields list the physical address for the tblspace **tblspace** entry for the table and the address of the first page of the first extent. The extent list shows the number of logical and physical pages in every extent.

The **-pT** option prints the same information as the **-pt** option. In addition, the **-pT** option displays:

- Index-specific information
- Page-allocation information by page type (for dbspaces)
- The number of any compressed rows in a table or table fragment and the percentage of table or table-fragment rows that are compressed
  If table or fragment rows are not compressed, the "Compressed Data Summary" section does not appear in the output.

Plan when you want to run the **-pT** option, because it forces a complete scan of partitions.

Output for both **-pt** and **-pT** contains listings for **Number of pages used**. The value shown in the output for this field is never decremented because the disk space allocated to a tblspace as part of an extent remains dedicated to that extent even after you free space by deleting rows. For an accurate count of the number of pages currently used, see the detailed information about tblspace use (organized by page type) that the **-pT** option provides.

Example of oncheck -pt Output

The following example shows output of the **oncheck -pt** command:

```
TBLspace Report for testdb:tab1

Physical Address                2:10
Creation date                   10/07/2004 17:01:16
TBLspace Flags                  801         Page Locking
                                                TBLspace use 4 bit bit-maps
Maximum row size                14
Number of special columns       0
Number of keys                  0
Number of extents               1
Current serial value            1
Pagesize (k)                    4
First extent size               4
Next extent size                4
Number of pages allocated       340
Number of pages used            337
Number of data pages            336
Number of rows                  75806
Partition partnum               2097154
Partition lockid                2097154

Extents
       Logical Page     Physical Page         Size Physical Pages
                  0             2:106         340         680
```

Example of oncheck -pT Output

The following example shows output of the **oncheck -pT** command:

```
TBLspace Report for database_a:nilesh.table_1a

                  Table fragment partition dbspace1 in DBspace dbspace1

    Physical Address                3:5
    Creation date                   03/21/2009 15:35:47
    TBLspace Flags                  8000901     Page Locking
                                                TBLspace contains VARCHARS
                                                TBLspace use 4 bit bit-maps
                                                TBLspace is compressed
    Maximum row size                80
    Number of special columns       1
    Number of keys                  0
    Number of extents               1
    Current serial value            100001
    Current SERIAL8 value           1
    Current BIGSERIAL value         1
    Current REFID value             1
    Pagesize (k)                    2
    First extent size               8
    Next extent size                8
    Number of pages allocated       24
    Number of pages used            22
    Number of data pages            14
    Number of rows                  500
    Partition partnum               3145730
    Partition lockid                3145730

    Extents
         Logical Page     Physical Page         Size Physical Pages
                    0           3:16053           24          24

Type                    Pages      Empty  Semi-Full       Full  Very-Full
    ---------------- ---------- ---------- ---------- ---------- ----------
    Free                        9
    Bit-Map                     1
    Index                       0
    Data (Home)                14
    Data (Remainder)            0          0          0          0          0
                     ----------
    Total Pages                24

    Unused Space Summary

        Unused data bytes in Home pages                1177
        Unused data bytes in Remainder pages              0

    Home Data Page Version Summary

                Version                                 Count

                    0 (current)                          14

    Compressed Data Summary

    Number of compressed rows and percentage of compressed rows  500 100.00
```

Note: oncheck -p[tT] now indicates the last time each index fragment was used for a query. This access time is stored on the partition page on disk, it will survive an instance restart.

Turn On Locking with -x

The **-x** option can be appended to the **-ci**, **-cI**, **-pk**, **-pK**, **-pl**, and **-pL** options to place a shared lock on affected tables. While the table is locked, no other users can perform inserts, updates, and deletions while **oncheck** checks or prints the index. Without the **-x** option for tables with row locking, **oncheck** only places an IS (intent shared) lock on the table, which prevents actions such as dropping the table or the indexes during the check.

For example, the following sample command instructs **oncheck** to lock indexes for the **customer** table while it validates the order of key values, validates horizontal links, and ensures that no node appears twice in the index:

```
oncheck -cix stores_demo:customer
```

When you specify option **-x**, **oncheck** locks indexes for tables that use row locking. If **oncheck** detects page-lock mode, it displays a warning message and places a shared lock on the table regardless.

Send Special Arguments to the Access Method with -u

You can use the **-u** option to send special arguments to the access method. The possible arguments depend on the access method. For example, the R-tree access method supports the **display** option, as the following example shows:

```
oncheck -pl -u "display"
```

Use commas to separate multiple arguments in the argument string.

For information on valid arguments for your access method, refer to the user manual for your access method.

Return Codes on Exit

The **oncheck** utility returns the following codes on exit.

```
GLS failures:-1
Invalid srial/key:2
Onconfig access error:2
Invalid onconfig settings:2
Invalid arguments to oncheck:2
Error connecting database server:1
Warning reported by oncheck:1
error detected by oncheck:2
no errors detected by oncheck:0
```

Windows only:

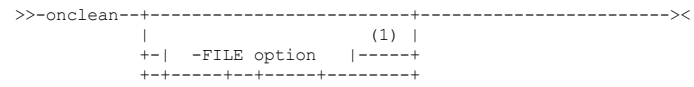
```
Not properly installed:1
Authentication error:2
```

The onclean utility

Use the **onclean** utility to force a shut down of the database server when normal shut down with the **onmode** utility fails or when you cannot restart the server. The **onclean** utility attempts to clean up shared memory, semaphores, and stops database server virtual processes.

Syntax

On UNIX and Linux, you must be user **root** or **informix** to run the **onclean** command. On Windows, you must be in the **Informix-Admin** group to run the command.



```
| '- -k-'  '- -y-'        |
'-+-----------+-----------'
  +- -V-------+
  '- -version-'
```

Notes:

1. See The -FILE option.

Table 1. Syntax Elements of the **onclean** Command

Element	Purpose
-k	Shuts down a server that is online by stopping database server virtual processes and attempting to clean up the remaining semaphores and shared-memory segments, even if they are still running.
-V	Displays short version information.
-version	Displays full version information.
-y	Does not prompt for confirmation.

Usage

Use the **onclean** utility to stop the database server only if the **onmode** utility is unable to shut it down or you cannot restart the server. Perhaps the database server shut down in an uncontrolled way and cannot recover, or it is hung. If the database server fails to restart, the previous instance of the database server is still attached to the shared-memory segments. Check the message log to see if the database server shut down abnormally. The **onclean** utility stops all **oninit** processes and attempts to remove all shared-memory segments and semaphores that are recorded in the **$INFORMIXDIR/etc/.conf.$INFORMIXSERVER** file.

Attention: Use the **onclean** utility with caution. When you run **onclean**, any pending transactions and processes fail to complete, and user sessions are disconnected abruptly. However, the database server rolls back transactions when it restarts.
The INFORMIXDIR, INFORMIXSERVER, INFORMIXSQLHOSTS, and ONCONFIG environment variables must be set with valid values to run this utility.

The **onclean** command that you use depends on the situation:

- If you are not sure whether the database server is offline, use the **onclean** command without options. If the database server is still online, a message appears directing you to run the **onclean -k** command.
- If the database server is offline, use the **onclean** command.
- If the database server is online and you are sure that you want to force it to shut down, use the **onclean -k** command.

You can use the **onclean** utility only to shut down the local database server; you cannot use it to shut down a remote database server. The **onclean** utility should not be used to shut down an entire high-availability cluster or a remote database server.

The **onclean** utility might not be able to clean up shared memory segments that were in use by the database server in every situation. The **onclean** utility attempts to terminate only **oninit** processes. The **onclean** utility does not succeed in the following situations:

- If a non-database server process is attached to the shared memory segment before running the **onclean** command, the **onclean** utility does not stop this process to remove the shared memory segment.
- The **onclean** might not be able to guarantee a clean server startup is when an application or database server utility is connected to a network port. If the user tries to initialize a database server instance on the same network port, then the database server cannot start the listener thread and fails to start. The **onclean** utility does not stop the application to free the network port.

You can automate shutting down the database server with the **onshutdown** script, which calls the **onclean -ky** command if necessary.

Return Codes

0
: Successful

1
: Failure because of one of the following problems:

  - Incorrect environment variable settings
  - Incorrect privileges to run the **onclean** command
  - Incorrect command syntax
  - Corrupted information
  - Running the **onclean** command without the **-k** option on a server that is still online

2
: Failure because one or more OS system calls used by **onclean** returned an error.

- The onshutdown script
  Use the **onshutdown** script to automate shutting down the database server. The script attempts to shut down the server normally. If the server has not shut down after a specified time, the script forces the server to shut down.

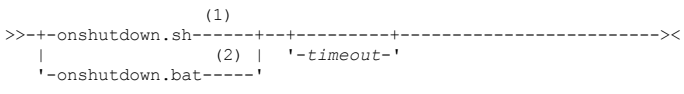
Related reference:
Taking the Database Server to Offline Mode with the -k Option

The onshutdown script

Use the **onshutdown** script to automate shutting down the database server. The script attempts to shut down the server normally. If the server has not shut down after a specified time, the script forces the server to shut down.

Syntax

The **onshutdown** script first runs the **onmode -ky** command. After a specified wait time, the script runs the **onclean -ky** command.
On UNIX and Linux, you must be user **root** or **informix** to run the **onshutdown** script. On Windows, you must be in the **Informix-Admin** group to run the **onshutdown** script.



Notes:

1. UNIX
2. Windows

Table 1. Syntax Elements of the **onshutdown** Script

Element	Purpose
timeout	The number of seconds after the **onmode -ky** command has been run before running the **onclean -ky** command. Must be a positive integer from 10 to 60. The default value is 30 seconds.

Usage

Use the **onshutdown** script only when forcing the database server to shut down would be appropriate.

Attention: Use the **onshutdown** script with caution. If the script needs to run the **onclean -ky** command, any pending transactions and processes fail to complete, and user sessions are disconnected abruptly. However, the database server rolls back transactions when it restarts.
The INFORMIXDIR, INFORMIXSERVER, INFORMIXSQLHOSTS, and ONCONFIG environment variables must be set with valid values to run this utility.

You can only use the **onshutdown** script to shut down the local database server; you cannot use it to shut down a remote database server. The **onshutdown** script should not be used to shut down an entire high-availability cluster or a remote database server instance.

The **onshutdown** script has a 10 second time period during which it can be aborted.

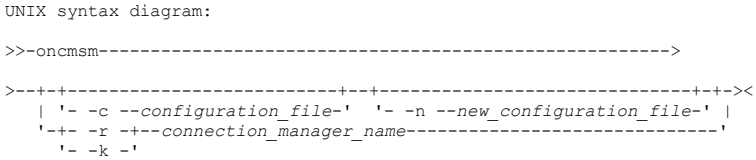
Taking the Database Server to Offline Mode with the -k Option

The oncmsm utility

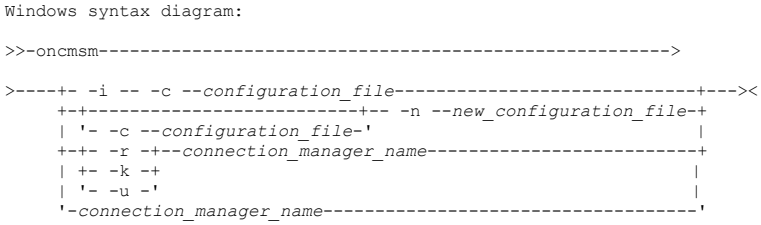
Use the **oncmsm** utility to start or shut down a Connection Manager, load a new configuration file into a Connection Manager to modify the Connection Manager's settings, or update the format of a configuration file.

Syntax

UNIX syntax diagram:



Windows syntax diagram:



Element	Purpose	Key considerations

Element	Purpose	Key considerations
-c	Starts the Connection Manager or converts a configuration file to the current Connection Manager format.	
connection_manager_name	Specifies the name of a Connection Manager instance.	
-i	Installs the Connection Manager as a Windows service.	This option is valid for Windows platforms only.
-k	Shuts down a specific instance of the Connection Manager.	
-n	Specifies the name of a converted configuration file.	
new_configuration_file	The name of file that is output to the $INFORMIXDIR/etc directory as part of the format-conversion process.	
configuration_file	The name of the configuration file located in the $INFORMIXDIR/etc directory.	If the configuration file is not specified, the Connection Manager attempts to load $INFORMIXDIR/etc/cmsm.cfg.
-r	Reloads the Connection Manager settings without stopping and restarting the Connection Manager.	
-u	Uninstall the Connection Manager Windows service.	This option is valid for Windows platforms only.

Usage

Run the **oncmsm** utility from the command line to initialize the Connection Manager. You can add, change, or delete Service Level Agreements (SLAs) while the Connection Manager is running and then reload the configuration file.

The Connection Manager configuration file in versions of IBM® Informix® Client Software Development Kit (Client SDK) prior to version 3.70.xC3 are incompatible with the current version of the Connection Manager. You must convert configuration files from versions prior to 3.70.xC3. You must have read permission on the configuration file you want to convert and write permission on the configuration file you want to create.

UNIX Only: The following users can run the **oncmsm** utility:

- User **informix**
- User **root**, if the user has privileges to connect to the **sysadmin** database
- A member of the **DBSA** group, if the user has privileges to connect to the **sysadmin** database

Windows Only: The following users can run the **oncmsm** utility:

- A member of the **Informix-Admin** group
- User **administrator**, if the user has privileges to connect to the **sysadmin** database
- A member of the **DBSA** group, if the user has privileges to connect to the **sysadmin** database

You must install the **oncmsm** utility as a service before you can start it.

The **oncmsm** utility can be started two ways:

- Run an **oncmsm** command.
- Click Start > Control Panel > Administrative Tools > Services and then start **oncmsm**.

If you are using multiple Connection Managers, you can run **onstat -g cmsm** to display the names of Connection Manager instances.

Example 1: Starting a Connection Manager (UNIX)

For the following example the Connection Manager's configuration_file_1 exists in the $INFORMIXDIR/etc directory. To start the Connection Manager, run the following command on the computer that the Connection Manager is installed on:

```
oncmsm -c configuration_file_1
```

The Connection Manager starts.

Example 2: Starting a Connection Manager (Windows)

For the following example the Connection Manager's configuration_file_1 exists in the $INFORMIXDIR/etc directory. To start the Connection Manager, run the following commands on the computer that the Connection Manager is installed on:

```
oncmsm -i -c configuration_file_2
oncmsm connection_manager_2
```

The Connection Manager named **connection_manager_2** starts.

Example 3: Stopping a Connection Manager

To stop the Connection Manager, run the following command on the computer that the Connection Manager is installed on:

```
oncmsm -k connection_manager_3
```

The Connection Manager named **connection_manager_3** stops.

Example 4: Reloading Connection Manager settings

For the following example, $INFORMIXDIR\etc\configuration_file_4 for a Connection Manager named **connection_manager_4** has changed. To update the Connection Manager's settings, run the following command on the computer that **connection_manager_4** is installed on:

```
oncmsm -r connection_manager_4
```

Example 5: Converting a Connection Manager configuration file to a current format

For the following example the Connection Manager's configuration file that is named cmsm.cfg exists in the $INFORMIXDIR/etc directory. To start the Connection Manager, run the following command on the computer that the Connection Manager is installed on:

```
oncmsm -n configuration_file_5
```

The **oncmsm** utility converts cmsm.cfg to the current configuration file format, and then outputs a file named configuration_file_5 into $INFORMIXDIR/etc/.

Example 6: Converting a specific Connection Manager configuration file to a current format

For the following example the Connection Manager's configuration file that is named configuration_file_4 exists in the $INFORMIXDIR/etc directory. To start the Connection Manager, run the following command on the computer that the Connection Manager is installed on:

```
oncmsm -c configuration_file_6 -n configuration_file_7
```

The **oncmsm** utility converts configuration_file_6 to the current configuration file format and then outputs a file named configuration_file_7 into $INFORMIXDIR/etc/.

Example 7: Uninstalling a Connection Manager (Windows)

For the following example, you have installed a Connection Manager named **connection_manager_4** as a Windows service. To unistall the Connection Manager, run the following command on the computer that the Connection Manager is installed on:

```
oncmsm -u connection_manager_4
```

The **oncmsm** utility uninstalls the Connection Manager.

Starting Connection Managers on Windows

The onconfig_diff utility

Use the **onconfig_diff** utility to compare two onconfig files.

Syntax

Element	Description
-d	Compares the current onconfig settings to the default settings.
-c	Compares one onconfig file to another.
-f *filepath_1*	Specifies the first file name to compare. Provide the path to the file unless the file is in the $INFORMIXDIR/bin directory.
-s *filepath_2*	Specifies the second file name to compare. Provide the path to the file unless the file is in the $INFORMIXDIR/bin directory.

Usage

Run the **onconfig_diff** utility to compare two different onconfig files. The **onconfig_diff** utility is in $INFORMIXDIR/bin.

The two files that you want to compare must be in the same directory.

Here are some ways that you can use the utility:

- Compare your current onconfig with the onconfig.std of same version.
- Compare your current onconfig with the onconfig.std of a newer version.
- Compare two onconfig files from different servers.

Example

In this example, the onconfig.std file is compared against the onconfig.production file:

```
$ onconfig_diff -c -f onconfig.std -s onconfig.production
```

Here is the output from this command:

```
=========================================
File 1: onconfig.std
File 2: onconfig.production
=========================================
Parameters Found in File 1, not in File 2
=========================================

FULL_DISK_INIT  0

NETTYPE         ipcshm,1,50,CPU

NUMFDSERVERS    4
...
=============================================
Parameters Found in File 2, not in File 1
=============================================

JVPJAVAHOME    $INFORMIXDIR/extend/krakatoa/jre

...
=============================================
Parameters Found in both files, but different
=============================================
ROOTPATH

File 1: $INFORMIXDIR/tmp/demo_on.rootdbs
File 2: /usr2/support/grantf/g1150fc8/rootdbs

LOGFILES

File 1: 6
File 2: 10

LOGSIZE

File 1: 10000
File 2: 3000
...
```

Related tasks:
Modifying the onconfig file

The ondblog utility

Use the **ondblog** utility to change the logging mode for one or more databases.

```
>>-ondblog--+-buf-------+--+-------------+---------------------><
            +-unbuf-----+  | .-,-------. |
            +-nolog-----+  | V         | |
            +-ansi------+  +---db_list-+-+
            +-cancel----+  '- -f--dbfile-'
            +- -V-------+
            '- -version-'
```

Element	Purpose	Key Considerations
buf	Sets the logging mode so that transaction information is written to a buffer before it is written to a logical log	None.
unbuf	Sets the logging mode so that data is not written to a buffer before it is written to a logical log	None.
nolog	Sets the logging mode so that no database transactions are logged	None.
ansi	Changes database logging to be ANSI compliant	Once you create or convert a database to ANSI mode, you cannot change it back to any of the other logging modes.
cancel	Cancels the logging-mode change request before the next level-0 backup occurs	None.
-f *dbfile*	Changes the logging status of the databases that are listed (one per line) in the text file whose pathname is given by *dbfile*	This command is useful if the list of databases is long or used often.
db_list	Names a space-delimited list of databases whose logging status is to be changed	If you do not specify anything, all databases that the database server manages are modified.

Usage

If you turn on transaction logging for a database, you must create a level-0 backup of all of the storage spaces that contain data in the database before the change takes effect.

For more information and examples of logging modes, see Modify the database-logging mode with ondblog.

Alternatively, you can change the logging mode by using an SQL administration API command with the alter logmode argument.

You cannot use the **ondblog** utility on High-Availability Data Replication (HDR) secondary servers, remote standalone (RS) secondary servers, or shared disk (SD) secondary servers.

Return codes

The **ondblog** utility logs messages in the BAR_ACT_LOG file.

For many of the return codes, you can check the ON-Bar logs to find the source of the problem:

1. Check the BAR_ACT_LOG file for accompanying messages.
2. Set the BAR_DEBUG configuration parameter to a positive integer and retry the operation.
3. Check the ON-Bar debug log file.

Table 1. Return codes for the ondblog utility

Return code	Description	User action
1	An error reading the onconfig file.	Check that the onconfig file is in the $INFORMIXDIR/etc/$ONCONFIG directory. If the BAR_ACT_LOG and BAR_DEBUG_LOG configuration parameters are set, make sure that the files are valid.
2	A linked list error.	See the accompanying message.
3	The user is not authorized to run the command.	Run the **ondblog** commands as the **root** user, user **informix**, as a Windows administrator, or as the owner of the database server.
4	Failed to set the INFORMIXSHMBASE environment variable to -1.	Contact Software Support.
5	The database server is not online.	Start the database server.
6	The command option is invalid.	Correct the spelling of the option.
7	Failed to communicate with the backup utility.	Check that the database server is online and that ON-Bar is configured.
9	Failed to allocate memory.	Check the ON-Bar logs for more information. You might need to ask your System Administrator to either increase your swap space or to install more memory in your system.
16	Failed to open the file.	Check the ON-Bar logs for more information.
17	Cannot change to the specified logging mode.	Check the ON-Bar logs for more information.
18	Failed to change the logging mode.	Check the ON-Bar logs for more information.
19	An SQL error occurred.	Check the ON-Bar logs for more information.
20	An empty list problem occurred.	Check the ON-Bar logs for more information.

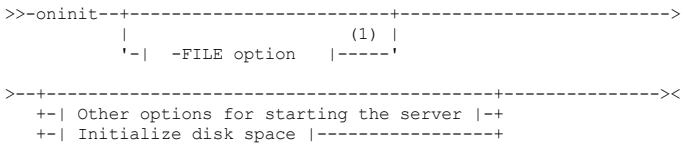
The oninit utility

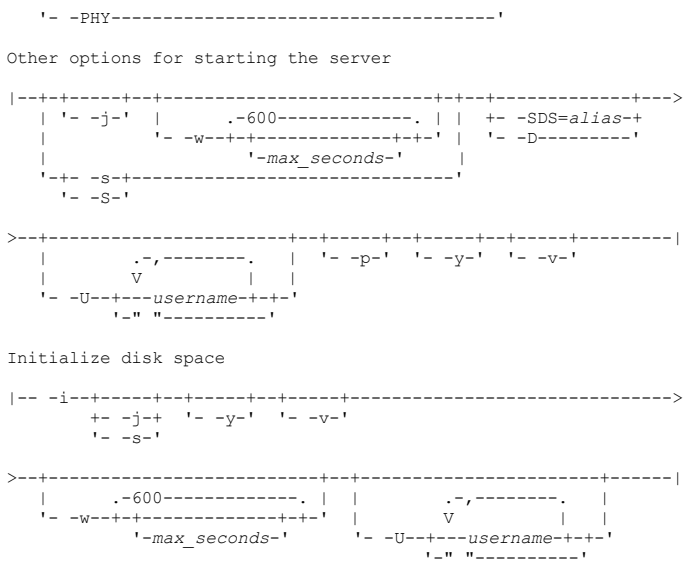
The **oninit** utility starts the database server.

On UNIX, Linux, and Mac OS X, you must be logged in as user **root**, user **informix**, or the non-root database server owner to run the **oninit** utility. User **informix** should be the only member of the group **informix**. Run the **oninit** command from the command line. You can allow users who belong to the DBSA group to run the **oninit** command. See Allow DBSA group users to run the oninit command (UNIX).

On Windows, IBM® Informix® runs as a Windows service. Any user who has appropriate permissions to start a Windows service is able to start the IBM Informix service. The Services control application runs the **oninit** utility with any options that you supply.

Syntax





Notes:

1. See The -FILE option.

Table 1. **oninit** command elements

Element	Purpose	Key Considerations
-D	Starts the database server with Enterprise Replication and high-availability cluster replication disabled.	
-i	Initializes disk space for the root dbspace so that it can be used by the database server and starts the database server.	Disk space needs to be initialized only once to prepare data storage for the server. By default, to prevent data loss, you cannot reinitialize disk space. To reinitialize disk space for an existing root dbspace, you must set the FULL_DISK_INIT configuration parameter to `1` and then run the **oninit -i** command. See Initialize disk space for the root dbspace.
-j	Starts the server in administration mode.	See Start the server in administration mode.
-p	Starts the database server without deleting temporary tables.	If you use this option, the database server starts more rapidly, but space used by temporary tables left on disk is not reclaimed.
-PHY	Starts the server as of most current checkpoint. The **-PHY** option is used to tell the server to do only physical recovery without logical recovery.	This option is normally used to start a secondary server. You must run one of the following commands to connect the secondary server to the primary server: `onmode -d secondary` `onmode -d RSS` The connection of the secondary server to the primary server fails if the most recent checkpoint on the primary server was not performed on the secondary server.
-s	Starts the server in quiescent mode.	The database server must be shut down when you use this option. When the database server is in quiescent mode, only the user **informix** can access the database server.
-S	Starts database server in quiescent mode as a standard server with high-availability data replication disabled.	When the database server is in quiescent mode, only the user **informix** can access the database server.
-SDS=*alias*	For shared disk servers, starts the current server and specifies the primary server with the alias name.	When both the primary server and all of the SDS servers are down, use the **-SDS=***alias* option to start the designated SDS server as the primary server. The **-SDS=***alias* flag cannot be combined with the **-i** flag.
-U *username*	Specifies which users can access the server in administration mode for the current session.	The **informix** user and members of the DBSA group are always administration mode users. See Start the server in administration mode.
-v	Displays verbose informational messages while the server is starting.	
-w *max_seconds*	Starts the database server and waits to indicate success or failure until the server is completely started in online mode or the number of seconds specified by *max_seconds* elapses.	The default number of seconds to wait is 600. This option is not valid on secondary servers in a high-availability cluster. See Start the server with a script.
-y	Prevents verification prompts.	The **-y** option automatically answers yes to all the verification prompts.

Usage

By default, the **oninit** utility shows verification prompts during server startup. You can suppress verification prompts by including the **-y** option. You can view verbose informational messages by including the **-v** option. On UNIX, Linux, and Mac OS X, **oninit** output is shown to standard output. On Windows, you can view **oninit** output by setting the ONINIT_STOUT environment variable to save the output to a file.

You can start the server in different operating modes. By default, if you run the **oninit** command without options, the server starts in online mode. When the database server is in online mode, all authorized users can access the server.

If you run an **oninit -FILE** command, you do not need to set local environment variables before you start the database server. The database server automatically uses the environment variables that are set as values in the **onconfig** file.

Start the server in administration mode

Administration mode is an administrator-only mode you can use to perform maintenance operations including those that require running SQL or DDL commands. When in administration mode, the database server only accepts connection requests from the following users:

- The **informix** user
- Members of the DBSA group
- Users specified by the **oninit -U** command or the **onmode -j -U** command, for the current session. The **-U** option overrides any users listed by the ADMIN_MODE_USERS configuration parameter in the onconfig file.
- Users specified by the ADMIN_MODE_USERS configuration parameter

Use the **-U** option with a list of comma-separated user names to add administration mode users, such as: `Karin,Sarah,Andrew`.

Use the **-U " "** option to remove all administration mode users except the **informix** user and members of the DBSA group: **oninit -U " "**.

Initialize disk space for the root dbspace

The first time you install IBM Informix on your system, disk space for the root dbspace for the database server needs to be initialized. The root dbspace is specified by the ROOTPATH configuration parameter.

If you performed a typical installation and chose to create a database server or you performed a customer installation, disk space was automatically initialized. Otherwise, you must initialize disk space by running the **oninit -i** command.

If the DISK_ENCRYPTION configuration parameter is set when you initialize the root dbspace, the root dbspace is encrypted.

If necessary, you can reinitialize disk space. Reinitializing disk space destroys all existing data managed by the database server. The database server must be offline when you reinitialize.

By default, you cannot reinitialize a root dbspace that is being used by the database server. Disk initialization fails if a page zero exists at the root path location (at the first page of the first chunk location). You can allow disk reinitialization of an existing root dbspace by setting the FULL_DISK_INIT configuration parameter to `1`.

Start the server with a script

You can use the **oninit -w** command in customized startup scripts and to automate startup. The **-w** option forces the server to wait until startup is completely successfully before indicating that the server is in online mode by returning to the shell prompt with a return code of `0`. If the server is not in online mode within the timeout period, the server returns a return code of `1` to the shell prompt and writes a warning message in the online log.

The default timeout is 600 seconds (10 minutes), which you can modify to any integer value.

After running the following command, if the server fails to start within 60 seconds, a code of `1` is returned to the prompt:

```
oninit -w 60
```

To determine the reason for the server failing to start, check the online log. You might need to increase the timeout value. When you use the **oninit -w** command in a script, you can check whether the server is online with the **onstat -** (Print output header) command.

Allow DBSA group users to run the oninit command (UNIX)

To allow users who belong to the DBSA group, other than the user **informix**, to run the **oninit** command, log in as the user **root** and change the permissions on the **oninit** utility in the $INFORMIXDIR/bin directory from 6754 to 6755.

- The -FILE option
  On UNIX, you can use the **-FILE** option to run certain IBM Informix utilities with the local environment variables that you set in your onconfig file. You do not have to set local environment variables before you run the command to start the utilities.
- Return codes for the oninit utility
  If a **oninit** command encounters an error, the database server returns an error message and a return code value.

The -FILE option

On UNIX, you can use the **-FILE** option to run certain IBM® Informix® utilities with the local environment variables that you set in your onconfig file. You do not have to set local environment variables before you run the command to start the utilities.

You can use the **-FILE** option when you start the following utilities: **oninit**, **oncheck**, **onclean**, **onload**, **onunload**, **onlog**, **onmode**, **onparams**, **onspaces**, **onstat**, and **ontape**.

Syntax

```
-FILE option

|--+---------+--+-----------+-----------------------------------|
   '- -FILE=-'  '-file_name-'
```

Table 1. **-FILE** option

Element	Purpose	Key Considerations
-FILE=*file_name*	Specifies the full path or relative path to the onconfig file that contains the environment information.	The **-FILE=***file_name* option must be the first argument in the command.

Usage

Before you run a command with the **-FILE** option, you must add directives to your onconfig file in the following format:

```
#$variable_name value
```

Any environment variables that are set in the onconfig file take precedence over the same environment variables that are set in the system or shell.

When you start a utility with the **-FILE** option, specify the full path or the relative path to the onconfig file. For example, both of the following examples start the database server with the environment information in the onconfig.serv1 file:

Full path

```
oninit -FILE=/opt/IBM/inf/etc/onconfig.serv1
```

Relative path

```
oninit -FILE=etc/onconfig.serv1
```

If the INFORMIXDIR environment variable is not set in the user system, the shell, or in the onconfig file, the value of INFORMIXDIR is set to the PATH of the executable program, with the assumption that the executable program is in a subdirectory of INFORMIXDIR. For example, you can run the **oninit -FILE=etc/onconfig.myserv** command when the **oninit** utility is in the /opt/IBM/informix/bin directory. If the INFORMIXDIR environment variable is not set in the shell or in the onconfig.myserv file, the value of INFORMIXDIR is set to /opt/IBM/informix.

If you use a form of remote execution, such as `ssh`, use the **-FILE** option to specify the path to the onconfig file on the remote computer.

Example

Suppose that you specified values for the INFORMIXSERVER, DBDATE, and SERVER_LOCALE environment variables in the onconfig file for the js_3 instance:

```
#onconfig.js_3
#
# *** Start environment settings for js_3
#
#$INFORMIXSERVER server3
#$DBDATE MDY4/
#$SERVER_LOCALE en_us.utf8
#
# *** End environment settings for js_3
```

The other important environment variables (INFORMIXDIR, INFORMIXSQLHOSTS, ONCONFIG) for running the utility are specified in the user environment. The path to the **oninit** executable program is part of the user environment and the onconfig file is in the current directory.

You can run the `oninit -FILE=onconfig.js_3` command from the current directory to start the database server, and automatically set the values for the INFORMIXSERVER, DBDATE, and SERVER_LOCALE environment variables.

Setting local environment variables for utilities

Return codes for the oninit utility

If a **oninit** command encounters an error, the database server returns an error message and a return code value.

The following table contains the return codes, message text, and user actions for the **oninit** utility.

Table 1. Return codes for the oninit utility

Return Code	Message Text	User Action
0	The database server was initialized successfully.	The database server started.
1	Server initialized has failed. Look at any error messages written to stderr or the online message log.	Take the appropriate action based on the error messages written to stderr or the online message log.
87	The database server has detected security violations or certain prerequisites are missing or incorrect.	(UNIX and Mac OS only) Check if user and group **informix** exists. Check if the server configuration file (onconfig) and sqlhosts file exists and has the correct permissions. Check if the environment variables INFORMIXDIR, ONCONFIG, and SQLHOSTS have a valid value and their length does not exceed 255 characters. Check if the environment variable INFORMIXDIR specifies an absolute path and does not have any spaces, tab, new lines, or other incorrect characters. Check if role separation-related subdirectories under the $INFORMIXDIR directory, such as aaodir and dbssodir, have the correct ownership. Run the **onsecurity** utility to diagnose and fix any issues.
170	The database server failed to initialize the dataskip structure.	Free some physical memory on the system and try to start the database server again.
172	The database server failed to initialize the listener threads.	Free some system resources, check the configuration parameter values for the number of listener threads to start when the database server starts up, and try to start the database server again.
173	The database server failed to initialize data replication.	Free some physical memory in the system and try to start the database server again.
174	The database server failed to start fast recovery threads.	Free some physical memory in the system and try to start the database server again.
175	The database server failed to initialize the root dbspace.	Check the root dbspace related parameters in server configuration file (onconfig) to make sure that the path for the root dbspace is valid.
176	Shared disk secondary server initialization failed.	Check the entries in sqlhosts file (UNIX) or SQLHOSTS registry key (Windows) to make sure that you are using the value of the DBSERVERNAME configuration for the primary server correctly. Check if the value for the SDS_PAGING configuration parameter in the server configuration file (onconfig) is correct. Free some system resources and try to start the database server again.
177	The database server failed to start the main_loop thread.	Free some physical memory on the system and try to start the database server again.
178	The database server failed to initialize the memory required for page conversion.	Free some physical memory on the system and try to start the database server again.
179	The database server was unable to start CPU VPs.	Free some physical memory on the system and try to start the database server again.
180	The database server was unable to start the ADM VP.	Free some physical memory on the system and try to start the database server again.
181	The database server failed to initialize kernel AIO.	Free some physical memory on the system and try to start the database server again.
182	The database server was unable to start IO VPs.	Free some physical memory on the system and try to start the database server again.
183	The database server failed to initialize the memory required for asynchronous I/O operations.	Free some physical memory on the system and try to start the database server again.
184	The database server failed to initialize memory required for parallel database queries. (PDQ)	Free some physical memory on the system and try to start the database server again.
185	The database server failed to initialize various SQL caches.	Free some physical memory on the system and try to start the database server again.
186	The database server failed to initialize the Global Language Support (GLS) component.	Free some physical memory on the system and try to start the database server again.
187	The database server failed to initialize the Associated Service Facility (ASF) components.	Check the entries in sqlhosts file.
188	The database server was unable to start the CRYPTO VP.	Free some physical memory on the system and try to start the database server again.
189	The database server was unable to initialize the alarm program.	Free some physical memory on the system and try to start the database server again.
190	The database server failed to initialize the auditing component.	Free some physical memory on the system and try to start the database server again.
192	The database server failed to restore the Window station and desktop.	(Windows only) Try to shut down the database server after freeing some system resources.
193	The database server failed to create daemon processes.	(UNIX and Mac OS only) Free some system resources and try to startup the database server once again.
194	The database server failed to redirect the file descriptors properly.	(UNIX and Mac OS only) Check the availability of the /dev/null device and try to start the database server again.

Return Code	Message Text	User Action
195	The database server failed to initialize the current directory for use.	Check the validity of the current working directory from where the database server is being initialized.
196	The database server failed to initialize the /dev/null device.	(AIX® only) Check the validity of the /dev/null device.
197	The database server failed to find the password information for the user trying to initialize the database server.	Verify that the user password is valid.
198	The database server failed to set the resource limits.	(UNIX and Mac OS only) Verify, and if required, increase the resource limits for processes on the host computer.
200	The database server did not have enough memory to allocate structures during initialization.	Free some physical memory on the system and try to start the database server again.
206	The database server could not allocate the first resident segment.	Check the values of the BUFFERPOOL and LOCKS configuration parameters in the server configuration file (onconfig) to make sure that they can be accommodated with the available memory on the host computer.
207	The database server failed to initialize shared memory and disk space.	Free some physical memory in the system, check the validity of all the chunks in the database server, and try to start the database server again.
208	The database server failed to allocate structures from shared memory.	Free some system resources and try to start the database server again.
209	The database server encountered a fatal error during the creation of shared memory.	Free some physical memory in the system and try to start the database server again.
210	The database server requested memory for the resident segment that exceeded the maximum allowed.	Reduce the size of the resident segment by lowering the values of the BUFFERPOOL and LOCKS configuration parameters.
220	The database server failed to read the audit configuration file.	Check that the audit configuration file (adtcfg) exists and is valid.
221	The database server could not detect the default directory for DUMPDIR. Usually it is the $INFORMIXDIR/tmp directory.	Create the $INFORMIXDIR/tmp directory if it is not present.
222	The database server detected an error in the value of the DBSERVERALIASES configuration parameter in the server's configuration file.	Verify that the values for the DBSERVERALIASES configuration parameter are valid and they have corresponding entries in the sqlhosts file (UNIX) or SQLHOSTS registry key (Windows).
223	The database server detected an error with the value of the DBSERVERNAME configuration parameter in the server's configuration file.	Verify that the value of the DBSERVERNAME configuration parameter is valid and it has a corresponding entry in the sqlhosts file (UNIX) or SQLHOSTS registry key (Windows).
224	The database server detected an error with the value of the HA_ALIAS configuration parameter in the server's configuration file.	Correct the value of the HA_ALIAS configuration parameter in the server configuration file (onconfig).
225	The database server detected too many entries for the NETTYPE configuration parameter or the DBSERVERALIASES configuration parameter in the server's configuration file.	Reduce the number of instances of the NETTYPE or DBSERVERALIASES configuration parameters in server configuration file (onconfig) and try to start the database server again.
226	The database server could not find an entry for the DBSERVERNAME configuration parameter in the sqlhosts file or the contents of the sqlhosts file are not valid.	Check the entries in the sqlhosts file.
227	Incorrect serial number.	Reinstall the database server.
228	The user does not have the necessary DBSA privileges to invoke the executable.	The user must have DBSA privileges or be a part of the Informix®-Admin group (Windows).
229	The database server could not initialize the security sub-system.	(Windows only) The user does not the necessary user rights on the host or is not part of the Informix-Admin group.
230	The database server, if started as a process on Windows platform , timed out while trying to build the required system databases during initialization. (Windows only)	Check the event log on the host to determine why the service could not be opened or could not be started. The database server might have timed out while trying to build the system databases. Free some system resources and try to start the database server again.
231	Informix service startup failed when the “oninit -w” command was run as a process on the command line.	(Windows only) Check the event log on the host to determine why the service start has failed.
233	The database server failed to initialize the Pluggable Authentication Module (PAM).	Check the configuration for the PAM library on the system.
235	The database server detected errors for certain configuration parameter values in the server's configuration file.	Inspect the server configuration file (onconfig) for any errors.
236	The database server detected an error while trying to restrict the allowable values for the Informix edition in use.	Check if the SDS_ENABLE configuration parameter is set to 1 in the server configuration file (onconfig). Check if the server name specified with the **oninit -SDS** command matches the value of the HA_ALIAS or DBSERVERNAME configuration parameter. Check if the shared disk used is part of an existing shared disk cluster.
237	The database server could not find the server configuration file.	Ensure that the server configuration file exists and is valid.
238	The database server detected an incorrect value for the INFORMIXSERVER environment variable or the value did not match the value of the DBSERVERNAME configuration parameter in the server's configuration file.	(Windows only) Check the value of the INFORMIXSERVER environment variable and the corresponding entry in the registry.

Return Code	Message Text	User Action
239	The database server detected an incorrect or non-existent value for the INFORMIXDIR environment variable.	(Windows only) Check the value of the INFORMIXDIR environment variable.
240	Incorrect command-line options were issued to the database server.	Correct the command-line options issued to the database server at startup.
248	The database server failed to create the Informix loader domain file.	(AIX only) Check if the /var/adm/ifx_loader_domain file is present.
249	The database server failed to dynamically load the PAM library.	The PAM library is not available for the database server. Install the PAM libraries.
250	The database server failed to dynamically load the ELF library.	The ELF library is not available to the database server. Install the **libelf** packages.
255	There was an internal error during server initialization. Look at any error messages written to stderr or to the online message log.	Take the appropriate action based on the error messages written to stderr or the online message log.

The onkstash Utility

Use the **onkstash** utility to create a password stash file for an existing PKCS#12 keystore.

A password stash file allows database clients or the database server itself access to their respective keystore without the inconvenience for the user to supply the password every time.

The **onkstash** utility accepts the file name of a PKCS#12 keystore (ending with extension ".p12") and the password for this keystore. It writes the password in an encrypted format to the password stash file. The name of this stash file is same as the keystore filename, but with the extension ".stl".

If the password for a keystore gets changed, the new password must be stashed again using the **onkstash** utility. If a password stash file exist with the old keystore password, then it is overwritten with the new password in an encrypted format.

Syntax

```
onkstash <keystore file> <password>
```

where **<keystore file>** is the name of the PKCS#12 keystore file, and **<password>** is the current password for the keystore.

Usage

The **onkstash** utility determines the file name for the password stash file from the name of the keystore file. It checks if the given password is correct and then writes it in an encrypted format to the stash file.

If the password stash file gets created by **onkstash**, the file access permissions are set to 600. If the password stash file already exists, the permissions are not changed. It is recommended to check the permissions for the keystore file as well as for the password stash file, and correct them if deemed necessary.

In addition to stashing the keystore password, the **onkstash** utility can also provide the version of the encryption library used. Run the command "onkstash -version" to determine, whether GSKit or OpenSSL is used as encryption library and the version of that library.

The onkstore Utility

Use the **onkstore** utility to create and manage password stash files for use with storage space encryption and the integrated backup encryption features.

The onkstore utility will create a password stash file in the $INFORMIXDIR/etc directory by default, but this file may be created and used from any location accessible by the database server as long as that directory has secure permissions.

With its informix/informix ownership and 600 permissions, the password stash file can be read only by users root or informix in UNIX/Linux and the creator of the keystore in Windows. In addition, the file is itself encrypted using a password. The admin must specify this *keystore password* when creating the keystore. By default that password will be stored (as an obfuscated value) in a stash file along side the keystore file. Do not remove the stash file or allow it to be separated from the keystore file. If you do not want the password to be stashed, use the option "-nostash" when creating the keystore. In that case the password may be supplied interactively to oninit and utilities such as *oncheck*, *onlog*, *ontape*, or *onbar*.

The onkstore utility can create different types of keystores. A keystore can contain either:

1. A *Master Encryption Key* (MEK) that is used as a “seed” by the server to encrypt storage spaces when using the Storage Space Encryption feature.
2. A set of credentials to access a Remote Key Server that stores the Master Encryption Key for the Storage Space Encryption (DISK_ENCRYPTION) or a set of credentials to access a Remote Key Server that stores the Remote Master Encryption Key used by the Integrated Backup Encryption feature (BAR_ENCRYPTION).

The onkstore utility has the following usage:

Table 1. onkstore usage

-file <fn>	name of keystore to create/list/convert.
-type	type of keystore to create: local, AWS-EAR, AWS-BAR, KMIP, AZURE-EAR, AZURE-BAR

-create	create a new keystore. By default stash the password in a stash file. Use option "-nostash" if this is not desired.
-pw <fn>	file with cleartext keystore password. If not provided and the password is not stashed already, it is prompted for interactively.
-list	list the contents of the file.
-cipher	cipher the server will use: aes128, aes192, aes256
-credential <fn>	file that contains credentials in json format.
-verify	verify the keystore.
-convert	convert keystore from one type to another.
-changepw [<fn>]	change the password for the keystore. <fn> is the file containing the new cleartext keystore password.
-nostash	upon creation of a keystore do not stash the password.
-help	print this message.

Note: -pw is not needed if your password is stashed.
Use the onkstore utility to perform the following tasks:

- Create a Keystore with onkstore
- Creating an AWS type keystore
- Creating an Azure type keystore
- Creating a KMIP type keystore
- Verifying a Keystore File
- Changing the Password for a Keystore File
- Converting a Keystore File
- List the contents of a Keystore File

Create a Keystore with onkstore

A keystore file is required by any instance that has the storage space encryption feature enabled. This keystore file has a ".p12" extension. It may also have an associated password stash file whose extension is ".sth".

When referring to a keystore file with onkstore or in the value of the DISK_ENCRYPTION configuration parameter, always omit the ".p12" extension.

A keystore file that contains your instance's encryption key is called a local keystore file. The simplest way to create a local keystore file is as follows:

```
onkstore -create -file my_keystore -type local -cipher aes128
```

The result of that command is a file located in the $INFORMIXDIR/etc directory called my_keystore.p12, which contains a 128-bit (16 byte) encryption key. That p12 file is encrypted using a password, which must be provided interactively when prompted for. By default, the password is stored in a stash file. The path to the stash file is $INFORMIXDIR/etc/my_keystore.sth.

To provide the new password on the command line when creating a new keystore, use these commands instead:

```
echo "sample_password" > pw_file
onkstore -file my_keystore -type local -cipher aes128 -pw pw_file
rm pw_file
```

The password must be at least 8 characters long. In this case "sample_passwd" would also be stashed encrypted in $INFORMIXDIR/etc/my_keystore.sth.

As the encryption password is known, the admin has the option of removing the stash file and supplying the password to **oninit** manually each time the server is booted:

```
oninit -pw
Please enter current encryption password: sample_password
```

Instead of supplying the password interactively, it may be passed to oninit using a file:

```
touch /tmp/mypassword
chmod 660 /tmp/mypassword
echo "sample_password" > /tmp/mypassword
oninit -pw /tmp/mypassword
rm /tmp/mypassword
```

The keystore file will be located in $INFORMIXDIR/etc by default, but you can also move or create it elsewhere by specifying a full path (minus the .p12 extension):

```
onkstore -create -file /work/KEYSTORES/my_keystore -type local -cipher aes128
```

If your keystore file is not located in $INFORMIXDIR/etc you must use the full path in your DISK_ENCRYPTION setting:

```
DISK_ENCRYPTION keystore=/work/KEYSTORES/my_keystore
```

Like $INFORMIXDIR/etc, the directory containing your keystore file must have ownerships of informix/informix.

When creating a keystore file with onkstore you must specify which of the three supported ciphers you wish to use: aes128, aes192, and aes256. By default the server assumes you are using aes128, but if not, the admin must specify the cipher in the DISK_ENCRYPTION setting:

```
DISK_ENCRYPTION keystore=my_keystore,cipher=aes256
```

The DISK_ENCRYPTION setting consists of comma-separated attributes and may contain no quotes or spaces.

A keystore file that contains AWS (Amazon Web Services) credentials instead of an encryption key is called a remote keystore file. Run the following command to create a remote keystore file interactively:

```
onkstore -create -file my_aws_keystore -type AWS_EAR -cipher aes192
```

onkstore will then prompt you for AWS credentials and other information that will identify the key you want to either create or use. For example:

```
 $ onkstore -create -file my_aws_keystore -type AWS_EAR -cipher aes192
Creating AWS EAR Keystore
AWS Key Id
>AKCAIPP520LF4AJBOTXA
AWS Key Secret
>TCEmlasjdflkjbasNHFAI6BHOwj4XHe50ic7LCt9
AWS Region
>us-east-1
AWS CMK Id
>16fd15d9-db8b-4cb7-9d99-d3070df97b58
SSM Key Location
>/informix/keys/aes192/key1
```

This is not your actual encryption key. They are merely pieces of information that when put together allow the server to access a particular encryption key stored in AWS. If the terms “CMK Id” and “AWS Region” are not familiar to you, it is because you do not yet have an AWS account set up. Familiarity with an AWS account you are able to manage is a prerequisite for creating a remote keystore file using onkstore.

Rather than providing these details to onkstore interactively you have the option of feeding a json file to the utility instead:

```
onkstore -create -file my_ks -cipher aes192 -credential /tmp/my_creds.json
```

In this case the /tmp/my_creds.json file would contain something like this:

```
{
"Credentials" :
{
"Type" : "aws-ear",
"AWS Key Id" : "AKCAIPP520LF4AJBOTXA",
"AWS Key Secret" : "TCEmlasjdflkjbasNHFAI6BHOwj4XHe50ic7LCt9",
"AWS Region" : "us-east-1",
"AWS CMK Id" : "16fd15d9-db8b-4cb7-9d99-d3070df97b58",
"SSM Key Location" : "/informix/keys/aes192/key1"
}
}
```

If this command is run and the master encryption key does not exist in AWS at the specified location (/informix/keys/aes192/key1), onkstore will attempt to generate one and store it there. If the credentials point to an existing key, onkstore will create the keystore file and leave the key as-is.

The -pw argument works the same way with remote keystore file creation as it does with local keystore creation.

Do not use the AWS-BAR type when creating a keystore for use with the storage space encryption feature. This type of keystore is used with the Integrated Backup Encryption feature.

Creating an AWS type keystore

If your remote key server is Amazon Web Services Key Management Service (AWS-KMS), you can create two types of keystore : “AWS-EAR” to be used by the Storage Space Encryption feature, or “AWS-BAR” to be used by the Integrated Backup Encryption feature.

The only difference between these credentials is that the AWS-EAR requires, also, access to the AWS Secrets Manager (AWS-SSM) where the IDS Master Encryption Key is stored.

When asked to create an AWS keystore, the following information must be readily available to the operator:

- AWS Key Id, this is not an encryption key, this is the AWS access key (the equivalent of a username) to get access to the AWS infrastructure. You can generate a “AWS Key Id”/”AWS Key Secret” pair (**AWS Services -> IAM -> Users -> “User Name” -> Security Credentials -> Access Keys**).
- AWS Key Secret, this is not an encryption key, this is the AWS secret key (the equivalent of a password) to get access to the AWS infrastructure. You can generate a “AWS Key Id”/”AWS Key Secret” pair (**AWS Services -> IAM -> Users -> “User Name” -> Security Credentials -> Access Keys**).
- AWS Region, this is the AWS region, all keys and CMKs are region bound, you must provide the region where you have your keys (ie us-east-1).
- AWS CMK Id, this is the id (or name) of the AWS Customer Master Key (Remote Master Encryption Key). This key never leaves the AWS infrastructure and it is used by onkstore to generate the master encryption key used by IDS with the Storage Spaces Encryption feature or the Backup Encryption Keys used by the Integrated Backup Encryption feature.
- SSM Key Location, this is needed only for AWS-EAR types of keystores. This is the hierarchical path where the IDS Master Encryption Key will be stored after being generated by onkstore. The MEK is encrypted using the CMK before being stored here.

To use a JSON file as input for onkstore, create a file with the following structure:

```
            {
              "Credentials" :
                {
                "Type" : "..." ,
                "AWS Key Id" : "...",
                "AWS Key Secret" : "...",
                "AWS Region" : "...",
                "AWS CMK Id" : "...",
                "SSM Key Location" : "..."
                }
            }
          where the value for "Type" is either "aws-ear" or "aws-bar".
```

Creating an Azure type keystore

If your remote key server is Microsoft Azure Key Vault you can create two types of keystore : “AZURE-EAR” to be used by the Storage Space Encryption feature, or “AZURE-BAR” to be used by the Integrated Backup Encryption feature.

The only difference between these credentials is that the AZURE-EAR requires, also, access to the Azure Secrets inside the Key Vault, where the IDS Master Encryption Key is stored.

When asked to create an AZURE keystore, the following information must be readily available to the operator:

- Azure Vault Url, this is the URL to access your key vault. This value is generated by the Azure system when a new keyvault is created (**Home -> All resources -> “Key Vault Name” -> Overview -> DNS Name**).
- Azure Client Id, the usage of this feature requires access to the Active directory infrastructure in Azure,for that you need to create a Web Application under your username and provide the “Application Id” (**Active Directory -> Users -> All User -> “User Id” -> Applications -> “Application Name” -> Application Id**).
- Azure Client Secret, When the Web Application is created, you will be provided with both the Application Id and the Application Secret. The application secret cannot be recovered after the application was created.
- Azure Directory Id, Your KeyVault is created under an Active Directory, you need to provide the Directory Id (**Home -> All resources -> “Key Vault Name” -> Overview -> Directory ID**).
- Azure Key Name, this is the name or full id of the Azure Key (Remote Master Encryption Key). This Key never leaves the Azure infrastructure and it is used by onkstore to encrypt the locally generated Master Encryption Key used by the IDS Storage Space Encryption feature. It is also used by the On-Bar/ontape utilities to encrypt the Backup Encryption Keys used by the Integrated Backup Encryption Feature. In Azure, you can provide a simple name for this key (ie “MY_IDS_MEK”) in which case we will use the LATEST key available (Each time the key is rotated a newer Id is available), or, you can specify the Id of the key you want to use (ie “ MY_IDS_MEK/wsdd6405fb584cf9a3c63f6926d2e92e”) in which case we will keep using the same key even if it is rotated.
- Azure Encrypt Algorithm, when you create the RMEK in Azure Key Vault, it allows you to select among several types of keys and depending on the type of key, you can select different algorithms to encrypt data with it. Select here a valid algorithm name for the type of RMEK you created.
- Azure Secret Name, The name of the secret where we will store the IDS MEK. This is used only if you create a AZURE-EAR type keystore. If you provide a simple name (ie “ INFORMIX-256BIT”) a new MEK will be generated and stored, the ID of the newly stored key will recorded. If you provide a full ID for the secret (“ INFORMIX-256BIT/ 284ded569a8b40be8e4de2254ddeedd7”), then we will try to retrieve the secret, if not present we will return an error.

To use a JSON file as input for onkstore, create a file with the following structure:

```
{
  "Credentials" :
    {
    "Type" : "...",
    "Azure Vault Url" : "...",
    "Azure Client Id" : "...",
    "Azure Client Secret" : "...",
    "Azure Directory Id" : "...",
    "Azure Key Name" : "...",
    "Azure Encrypt Algorithm" : "...",
    "Azure Secret Name" : "..."
    }
}
```

```
where the value for "Type" is either "azure-ear" or "azure-bar".
```

Creating a KMIP type keystore

If your remote key server is located in a server/cluster supporting the KMIP standard you can create a single type of keystore (KMIP). At this moment, the same keystore type can be used by both the Storage Space Encryption and Integrated Backup Encryption features.

For Integrated Backup Encryption, this type of keystore works similarly with Azure and AWS: We provide the Key name of a RMEK that is used to encrypt the Backup Encryption Keys.

For Storage Space Encryption, the Key Name provided is the IDS MEK.

When asked to create a KMIP type keystore, following information must be readily available to the operator:

- KMIP Server, the IP address or hostname where the KMIP server is listening for request. If the port where the server listens is different from the default (5696), the port must be specified (ie “myserver.hcl.com:2356).
- KMIP Username, username to access the KMIP server. This is optional since in most cases, the access to the server is done by using SSL certificates.
- KMIP Password, password for the given username. This is also optional.
- KMIP Client Certificate File, a file containing the certificate for the client, The file must also contain the Private Key matching the certificate. The private key is expected to be a PKCS#8 key. The certificate is expected to have Authentication extensions.
- KMIP CA Certificate File, a file containing the root CA used to sign both the KMIP Client Certificate File and the KMIP Server Certificate File.
- KMIP Key Name, The name of the KMIP Key used as MEK by the Storage Spaces Encryption feature or as RMEK by the Integrated backup Encryption Feature. It is optional. If not present, onkstore will generate a new key and report its Id to the operator.

To use a JSON file as input for onkstore, create a file with the following structure:

```
{
  "Credentials" :
    {
    "Type" : "..." ,
    "KMIP Server" : "...",
    "KMIP Username" : "...",
    "KMIP Password" : "...",
    "KMIP Client Certificate File" : "...",
```

```
                "KMIP CA Certificate File" : "...",
                "KMIP Key Name" : "..."
                }
            }

          where the value for "Type" is "kmip".
```

Verifying a Keystore File

After creating a network keystore file and before deploying it, it is important to verify that its credentials work correctly. To do this, run the following command:

onkstore -file my_keystore -verify

onkstore will use the credentials contained in your keystore file to communicate with AWS and report success or failure:

```
$ onkstore -file my_keystore -verify
Keystore Verify Successful.
Key exists in AWS SSM /informix/keys/aes192/key1 for cipher aes192.
```

Changing the Password for a Keystore File

At any time using onkstore the admin may change the password of a keystore:

onkstore -file my_keystore -pw /tmp/old_password -changepw /tmp/new_password

If your current password is stashed (contained in the keystore's associated .sth file), then you do not need to pass it to onkstore via the -pw argument, but if you have removed the stash file you must provide the current password to onkstore before it can be changed to a new one.

You can also perform this same function using the "master_key reset" sysadmin command:

```
dbaccess sysadmin -<<END
execute function task("master_key reset","new_sample_pw");
END
```

This method has the advantage of not requiring the current password in order to change to a new one. The current password was provided to the server at boot time.

Converting a Keystore File

The convert feature is currently used only for EAR types of keystores. It supports to download the Master Encryption Key contained in the Remote Key Server (ie a KMIP server) to the local keystore. The old keystore containing the credentials to the RKS will be renamed and will be replaced with a new one of type "local".

Since the Integrated backup encryption feature does not store a Master Encryption Key at the RKS and does not support keystore of type "local", this option is not needed/supported for credentials of type AWS-BAR and AZURE-BAR.

```
$ onkstore -file my_keystore -convert
Which type of keystore would you like to create:
1 - Local Keystore
2 - AWS EAR Keystore
3 - AWS BAR Keystore
4 - KMIP EAR Keystore
5 - AZURE EAR Keystore
6 - AZURE BAR Keystore

Conversion complete for /vobs/tristarp/sqldist/etc/my_keystore.p12
```

Currently, only option 1 (converting to a local keystore file) is supported. The original keystore file is copied to a backup file (my_keystore.p12.bak#) before being overwritten during the conversion.

Note: By downloading your MEK to a local machine, you are increasing the chances of exposing that key, which is the reason to use a RKS in the first place.

List the contents of a Keystore File

This command will not display your encryption key or your AWS credentials. It displays the kinds of objects stored in the file. For example:

```
$ onkstore -file /work3/keystores/test_keystore -list
List the contents of keystore /work3/keystores/test_keystore.p12
KeystoreType
AWS Key Id
```

```
AWS Key Secret
AWS Region
AWS CMK Id
SSM Key Location
```

An admin may list the basic contents of a file as a sort of sanity check.

The onlog utility

The **onlog** utility displays the contents of a logical-log file, either on disk or on backup.

onlog: Display Logical-Log Contents

The **onlog** output is useful in debugging situations when you want to track a specific transaction or see what changes have been made to a specific tblspace. (For information about interpreting the logical-log file contents, see Interpreting Logical-Log Records.)

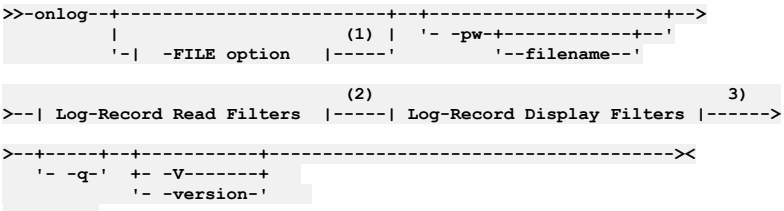
Any user can run all of the **onlog** options except the **-l** option. Only user **informix** on UNIX or a member of the **Informix-Admin** group on Windows can run the **-l** option.

If the database server is in offline mode when you execute **onlog**, only the files on disk are read. If the database server is in quiescent or online mode, **onlog** also reads the logical-log records stored in the logical-log buffers in shared memory (after all records on disk have been read).

When the database server reads a logical-log file with status U from disk while in online mode, the database server denies all access to the logical-log files, effectively stopping database activity for all sessions. (For more information, see onstat -l command: Print physical and logical log information.) For this reason, it is recommended that you wait until the files have been backed up and then read the contents of the logical-log files from backup.

The **onlog** utility does not have a functionally equivalent SQL administration API *command* string.

onlog Syntax



Note: The -pw option is required only when the Storage space encryption feature is enabled, stash file is in use, and the server is off-line. Supply an optional path to a file containing the keystore password, otherwise onlog will prompt for a password before displaying the requested log(s).

Element	Purpose	Key Considerations
-q	Suppresses the initial header and the one-line header that appears every 18 records by default	None.
-V	Displays the software version number and the serial number	See Obtaining utility version information.
-version	Displays the build version, host, OS, number and date, as well as the GLS version	See Obtaining utility version information.

You direct **onlog** to read the following portions of the logical log as it searches for records to display:

- Records stored on disk
- Records stored on backup media
- Records from the specified logical-log file

By default, **onlog** displays the logical-log record header, which describes the transaction number and the record type. The record type identifies the type of operation performed.

In addition to the header, you can use the read filters to direct **onlog** to display the following information:

- Logical-log record header and data (including copies of simple large objects stored in a dbspace or tblspace)
- Copies of blobpages from blobspaces
  They are copied from the logical-log backup only. They are not available from disk.

You can display every logical-log record header, or you can specify output based on the following criteria:

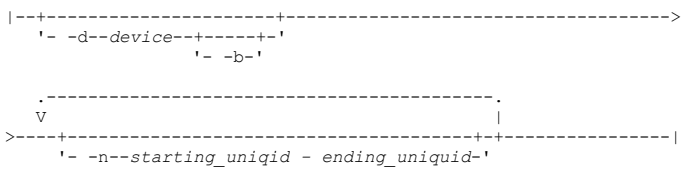
- Records associated with a specific table
- Records initiated by a specific user
- Records associated with a specific transaction

If **onlog** detects an error in the log file, such as an unrecognizable log type, it displays the entire log page in hexadecimal format and terminates.

Log-Record Read Filters

The **onlog** utility uses the pathnames that are stored in the root dbspace reserved pages to locate the logical-log files. If you use ON-Bar to back up the logical logs, **onlog** asks the storage manager to retrieve the appropriate logical-log records from the backup media.

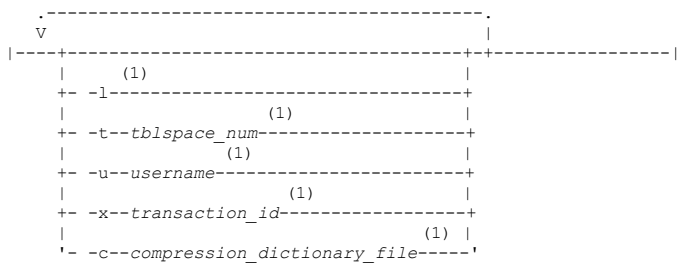
Syntax



Element	Purpose	Key Considerations
-b	Displays logical-log records associated with blobspace blobpages	The database server stores these records on the logical-log backup media as part of blobspace logging.
-d *device*	Names the pathname of the storage device where the desired logical-log backup is mounted	If you use **ontape**, the device that you name must be the same as the pathname of the device assigned to the configuration parameter LTAPEDEV. If the **-d** option is not used, **onlog** reads the logical-log files stored on disk, starting with the logical-log file with the lowest *logid*. If you use ON-Bar to back up logical logs, use the **onbar -P** command to view the contents of a logical-log file. See the *IBM® Informix Backup and Restore Guide*. For pathname syntax, see your operating-system documentation.
-n *starting_uniqid-ending_uniqid*	Directs **onlog** to read all the logical-log records contained in the log file that you specified from *starting uniqid* to the *ending uniqid*.	The *starting_uniqid* and the *ending_uniqid* are the unique ID numbers of the logical log. To determine the *uniqid* of a particular logical-log file, use the **onstat -l** command. If you do not use the **-n** option, **onlog** reads all the logical-log files that are available (either on disk or on tape). For information about the **onstat** utility, see Monitor the database server status.

Log-Record Display Filters

Syntax



Notes:

1. Only one occurrence of this item allowed

Element	Purpose	Key Considerations
-l	Displays the long listing of the logical-log record.	The long listing of a log record includes a complex hexadecimal and ASCII dump of the entire log record. The listing is not intended for casual use.
-t*tblspace_num*	Displays records associated with the tblspace that you specify.	Unsigned integer. Number, greater than 0, must be in the **partnum** column of the **systables** system catalog table. Specify this value as either an integer or hexadecimal value. (If you do not use a 0x prefix, the value is interpreted as an integer.) To determine the tblspace number of a particular tblspace, query the **systables** system catalog table as described in Tblspace Numbers.
-u *username*	Displays records for a specific user.	User name must be an existing login name. User name must conform to operating-system-specific rules for login name.
-x *transaction_id*	Displays only records associated with the transaction that you specify.	Value must be an unsigned integer between 0 and TRANSACTIONS - 1, inclusive. You should need to use the **-x** option only in the unlikely case that an error is generated during a rollforward. When this situation occurs, the database server sends a message to the message log that includes the transaction ID of the offending transaction. You can use this transaction ID with the **-x** option of **onlog** to investigate the cause of the error.

Element	Purpose	Key Considerations
-c *compression_ dictionary_file*	Uses the compression dictionary to expand compressed data and display uncompressed data.	If the **onlog** command contains the **-l** option and the **-c** option and there are compressed images in the log records, the **onlog** utility uses the compression dictionary to expand all expandable images in the log records. A compressed image is expandable only if there is a valid compression dictionary for that log record in the compression dictionary file. If **-c** is not specified or the compression dictionary file does not contain a valid compression dictionary for the compressed image, the **onlog** utility will display the row image in its compressed format.

If you do not have a compression dictionary file, you can use an UNLOAD statement to unload the compression dictionary, which is contained in the **syscompdicts_full** table in the **sysmaster** database, to a compression dictionary file, as follows:

```
UNLOAD TO 'compression_dictionary_file'
   SELECT * FROM sysmaster:syscompdicts_full;
```

If you do not specify any options, **onlog** displays a short listing of all the records in the log. You can combine options with any other options to produce more selective filters. For example, if you use both the **-u** and **-x** options, **onlog** displays only the activities that the specified user initiated during the specified transaction. If you use both the **-u** and **-t** options, **onlog** displays only the activities initiated by the specified user and associated with the specified tblspace.

alter logmode argument: Change the database logging mode (SQL administration API)

The onmode utility

Use the **onmode** utility to change the database server operating mode and perform various other operations on shared memory, sessions, transactions, parameters, and segments.

These topics show how to use the **onmode** options. If you do not use any options, the database server returns a usage statement.

On UNIX, you must be user **root** or user **informix** to run the **onmode** utility.

On Windows, you must be a member of the **Informix-Admin** group or the Administrators group to run the **onmode** utility.

For information on the **onmode -b** command, which is only used if you upgraded to a new version of Informix® and need to revert your databases to the previous version of the server, see Syntax of the onmode -b command in the *IBM® Informix Migration Guide*.

All **onmode** command options have equivalent SQL administration API *command* strings, except **onmode -b**, **onmode -BC**, and **onmode -R**.

- onmode command syntax
  Use **onmode** utility commands to perform various database server operations.
- onmode -a: Add a shared-memory segment
- onmode -BC: Allow large chunk mode
- onmode -c: Force a checkpoint
- onmode -C: Control the B-tree scanner
  Use the **onmode -C** command to control the B-tree scanner and specify information about B-tree scanner threads.
- onmode -cache surrogates: Cache the allowed.surrogates file
- onmode -d: Set data-replication types
- onmode -d: Set High Availability server characteristics
- onmode -d command: Replicate an index with data-replication
- onmode -D, -M, -Q, -S: Change decision-support parameters
- onmode -e: Change usage of the SQL statement cache
- onmode -F: Free unused memory segments
  Use the **onmode -F** command to free shared-memory segments that are unavailable or no longer needed for a process
- onmode -h: Update sqlhosts caches
- onmode -I: Control diagnostics collection
  Use the **onmode -I** option to start and stop diagnostics collection.
- onmode -k, -m, -s, -u, -j: Change database server mode
- onmode -l: Switch the logical-log file
- onmode -n, -r: Change shared-memory residency
- onmode -O: Override ONDBSPACEDOWN WAIT mode
- onmode -p: Add or drop virtual processors
  Use the **onmode -p** command to dynamically add or drop virtual processors for the database server instance. The **onmode -p** command does not update the onconfig file.
- onmode -P: Start, stop, or restart a listen thread dynamically
  Use the **onmode -P** command to start, stop, or restart an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.
- onmode -R: Regenerate .infos.dbservername File
- onmode -W: Change settings for the SQL statement cache
- onmode -we: Export a file that contains current configuration parameters
  Use the **onmode -we** command to create and export a configuration file that is a snapshot of your current configuration parameters.
- onmode -wf, -wm: Dynamically change certain configuration parameters
  Use the **onmode -wf** or **onmode -wm** command to dynamically change specific configuration parameters.
- onmode -wi: Import a configuration parameter file
  Use the **onmode -wi** command to import a file that contains new values for multiple configuration parameters. If the parameters are tunable, which means they can be updated individually with an **onmode -wm** command, the database server applies the new values.
- onmode -Y: Dynamically change SET EXPLAIN
- onmode -z: Kill a database server session
- onmode -Z: Kill a distributed transaction

onmode command syntax

Use **onmode** utility commands to perform various database server operations.

The following syntax diagram shows all of the options that you can use with the **onmode** command. The syntax diagram does not show all of the elements that you use with each command option. For the complete syntax of each command, see the topic on that command.

Syntax

```
>>-onmode--+------------------------+-------------------------->
           |                   (1) |
           '-|  -FILE option   |-----'

>--+- -a----------------+--+-----------+--+-----+-------------><
   |     (2)            |  +- -V-------+  '- -y-'
   +- -b----------------+  '- -version-'
   +- -BC---------------+
   +- -C----------------+
   +- -c----------------+
   +- -cache surrogates-+
   +- -e----------------+
   +- -d----------------+
   +-+- -D-+------------+
   | +- -M-+            |
   | +- -Q-+            |
   | '- -S-'            |
   +- -F----------------+
   +- -h-+---------+----+
   |     '- force -'    |
   +- -I----------------+
   +-+- -j-+------------+
   | +- -k-+            |
   | +- -m-+            |
   | +- -s-+            |
   | '- -u-'            |
   +- -l----------------+
   +-+- -n-+------------+
   | '- -r-'            |
   +- -O----------------+
   +- -P----------------+
   +- -p----------------+
   +- -R----------------+
   +- -W----------------+
   +-+- -wf-+-----------+
   | '- -wm-'           |
   +-+- -we-+-----------+
   | '- -wi-'           |
   +- -Y----------------+
   +- -Z----------------+
   '- -z----------------'
```

Element	Purpose	Key Considerations
-y	Causes the database server to automatically respond yes to all prompts	None.
-V	Displays the software version number and the serial number	See Obtaining utility version information.
-version	Displays the build version, host, OS, number and date, as well as the GLS version	See Obtaining utility version information.

onmode -a: Add a shared-memory segment

Syntax

```
>>-onmode-- -a--seg_size---------------------------------------><
```

Element	Purpose	Key considerations
-a *seg_size*	Allows you to add a new virtual shared-memory segment. Size is specified in kilobytes	Restriction: The value of ***seg_size*** must be a positive integer. It must not exceed the operating system limit on the size of shared-memory segments.

Ordinarily, you do not need to add segments to the virtual portion of shared memory because the database server automatically adds segments as they are needed. However, as segments are added, the database server might reach the operating-system limit for the maximum number of segments before it acquires the memory that it needs. This situation typically occurs when the SHMADD configuration parameter is set so small that the database server exhausts the number of available segments before it acquires the memory that it needs for some operation.

You can use this command to add a segment that is larger than the size specified by the SHMADD configuration parameter. By using this command to add a segment, you can adhere to the operating system limit for segments while meeting the need that the database server has for additional memory.

This command has an equivalent SQL administration API function.

Related reference:
add memory argument: Increase shared memory (SQL administration API)
onmode and a arguments: Add a shared-memory segment (SQL administration API)

onmode -BC: Allow large chunk mode

Syntax:

```
>>-onmode--+- -BC 1-+-------------------------------------------><
           '- -BC 2-'
```

Element	Purpose	Key Considerations
-BC 1	Enables support of large chunks, large offsets that are greater than 2 GB, and allows up to 32,768 chunks per instance.	This option allows large chunks to be created. Reversion without dropping the dbspace is possible if no chunks are larger than 2 GB. Dbspaces and blobspaces without chunks greater than 2 GB remain in the old format. After a chunk larger than 2 GB is added to a dbspace or blobspace then all chunks added or altered in that dbspace or blobspace are in the new format. See your *IBM® Informix Administrator's Guide*.
-BC 2	Allows large-chunk-only mode for all dbspaces.	Reversion is not possible. Enables the 9.4 large chunk feature for all dbspaces and blobspaces, Any chunk or offset added or modified has the new format. Existing chunks that you do not alter remain in the old format. See your *IBM Informix Administrator's Guide*

The **onmode -BC** (backward-compatible) commands are useful if you have converted from Informix® 9.40 (small chunk mode) to Informix 10.0 or later. When Informix 10.0 or later is first initialized (with the **oninit -iyv** command), by default it comes online with large chunk mode already fully enabled. Reversion is not possible. In the case of a newly initialized instance of Informix 10.0 or later, the **onmode -BC** commands will return an error.

Note: After executing the **onmode -BC** command, perform a complete system level-0 backup.

onmode -c: Force a checkpoint

Syntax:

```
>>-onmode-- -c--+--------------------+-------------------------><
               |        .- 15 ----. |
               +-block--+---------+-+
               |        '-timeout-' |
               '-unblock------------'
```

Element	Purpose	Key considerations
-c	Forces a checkpoint that flushes the buffers to disk.	You can use the **-c** option to force a sync checkpoint if the most recent checkpoint record in the logical log was preventing the logical-log file from being freed (status U-B-L).
block	Blocks the database server from any transactions.	While the database server is blocked, users can access it in read-only mode. Use this option to perform an external backup on IBM® Informix®. For more information, see the *IBM Informix Backup and Restore Guide*.
timeout	Specifies the number of seconds to wait for checkpoints to clear before returning to the command prompt.	The *timeout* option applies only if the DELAY_APPLY configuration parameter is configured (see DELAY_APPLY Configuration Parameter. If the DELAY_APPLY configuration parameter is enabled, the checkpoint requested by the primary server might not arrive at the secondary server for an extended period of time. It is also possible that no other checkpoints are staged in the staging directory. The default timeout value is 15 seconds and the maximum timeout allowed is 10 minutes (600 seconds). See *IBM Informix Backup and Restore Guide*.
unblock	Unblocks the database server.	When the database server is unblocked, data transactions and normal database server operations can resume. Use this option after you complete an external backup on IBM Informix. For more information, see the *IBM Informix Backup and Restore Guide*.

This command has an equivalent SQL administration API function.

Related reference:
checkpoint argument: Force a checkpoint (SQL administration API)
onmode and c arguments: Force a checkpoint (SQL administration API)

onmode -C: Control the B-tree scanner

Use the **onmode -C** command to control the B-tree scanner and specify information about B-tree scanner threads.

Syntax:

```
>>-onmode-- -C--+-(yielding syntax)--+------------------------><
                +-start--------------+
                +-count--------------+
                +-stop--count--------+
                +-kill    -count-----+
                +-threshold--size----+
                +-duration--num------+
                +-rangesize--size----+
                +-alice--mode--------+
                '-compression--value-'
```

Element	Purpose	Key considerations
-C	Controls the B-tree scanner for cleaning indexes of deleted items	There is no limit to the number of threads that can run at one time. However, there is a limit of 128 threads that can be started at one time. If, for example, you wanted 150 threads to run, you could execute two commands: **onmode -C 100** and **onmode -C 50.**
start *count*	Starts additional B-tree scanner threads.	If *count* is not specified, a *count* of 1 is assumed. There is no limit on the number of scanner threads that can be specified.
stop *count* **kill** *count*	Stops B-tree scanner threads.	If *count* is not specified, a *count* of 1 is assumed. Stopping all index scanners prevents all index cleaning. Either of these commands stop the B-tree scanner.
threshold size*count*	Sets the minimum number of deleted items an index must encounter before an index is placed on the hot list.	Once all indexes above the threshold have been cleaned and there is no other work for the B-tree scanner to do, the indexes below the threshold are added to the hot list.
duration *num*	The number of seconds that the hot list is valid.	After this number of seconds expires, the hot list will be rebuilt by the next available B-tree scanner thread, even if unprocessed items are on the list. Scanners currently processing requests are not interrupted.
rangesize *size*	Determines the size of an index before index range cleaning is enabled.	A size of `-1` can be used to disable range scanning.
alice *num*	Sets the system's **alice** mode.	Valid *num* values range from `0` (`OFF`) to `12`.
compression *value*	For a database server instance, modifies the level at which two partially used index pages are merged. The pages are merged if the data on those pages totals a set level.	Valid values for the level are `low`, `med` (medium), `high`, and `default`. The system default value is `med`.

The B-tree scanner has statistical information which tracks index efficiency and how much extra work the index currently places on the server. Based on the amount of extra work the index has accomplished because of committed deleted index items, the B-tree scanner develops an ordered list of indexes that have caused the server to do extra work. This list is called the hot list. The index causing the highest amount of extra work is cleaned first and the rest of the indexes are cleaned in descending order. The DBA can allocate cleaning threads dynamically, thus allowing for configurable workloads.

This command has an equivalent SQL administration API function.

Related reference:
onmode and C arguments: Control the B-tree scanner (SQL administration API)
set index compression argument: Change index page compression (SQL administration API)
BTSCANNER Configuration Parameter

onmode -cache surrogates: Cache the allowed.surrogates file

Syntax:

```
>>-onmode-- -cache surrogates-----------------------------------><
```

Element	Purpose	Key considerations
-cache surrogates	Reads the /etc/informix/allowed.surrogates file and stores the user IDs and group IDs values in shared memory cache. The user names and group names specified in allowed.surrogates file have to be valid operating system users and groups. The names are converted to corresponding UIDs and GIDs.	You can use **onmode -cache surrogates** during a session to load the allowed.surrogates file. The allowed.surrogates file is used specify users and groups who can act as surrogates for mapped users. The allowed.surrogates file will be automatically checked before a new connection is made to the database server or when users are created or altered. If the cache-refresh fails, the existing surrogate cache is cleared, effectively disabling mapped users. Existing connections on the server will be unaffected by changes in shared-memory cache. Changes in shared memory cache affect new sessions.

Related information:

Mapped user surrogates in the allowed.surrogates file (UNIX, Linux)
Specifying surrogates for mapped users (UNIX, Linux)
Surrogate user properties (UNIX, Linux)

onmode -d: Set data-replication types

Syntax:

```
>>-onmode-- -d--+-standard----------------+--------------------><
               '-+-primary---+--ha_alias-'
                 '-secondary-'
```

Element	Purpose	Key Considerations
-d	Used to set a server's data-replication type.	You can use the **-d standard** option when the database server is in quiescent, online, or read-only mode.
ha_alias	Identifies the high-availability alias of the primary or secondary database server.	The high-availability alias is the server's HA_ALIAS configuration parameter value. The *ha_alias* argument of the other database server in the data-replication pair and the database server's type (standard, primary, or secondary) is preserved after reinitialization of shared memory.

Using the -d standard option

The **-d standard** option drops the connection between database servers in a data replication pair (if one exists) and sets the database server type of the current database server to standard. This option does not change the mode or type of the other database server in the pair.

Use the **onmode -d standard** command only to disconnect a primary server from an HDR secondary server. Running the command converts the HDR secondary server to a standalone server. You should not run the **onmode -d standard** command to disconnect a primary server from an RS secondary server. To disconnect a primary server from an RS secondary server run the following commands:

On the RS secondary server:

```
onmode -d standard
```

On the primary server:

```
onmode -d delete RSS rss_ha_alias
```

Using the -d primary option

The **-d primary** option sets the database server type to primary and attempts to connect with the database server that *dbservername* specifies. If the connection is successful, data replication is turned on. The primary database server goes into online mode, and the secondary database server goes into read-only mode. If the connection is not successful, the database server is in online mode, but data replication is not turned on.

Using the -d secondary option

The **-d secondary** option sets the database server type to secondary and attempts to connect with the database server that *ha_alias* specifies. If the connection is successful, data replication is turned on. If the primary database server goes online, and the secondary database server goes into read-only mode. If the connection is not successful, the database server is in read-only mode, but data replication is not turned on.

This command has an equivalent SQL administration API function.

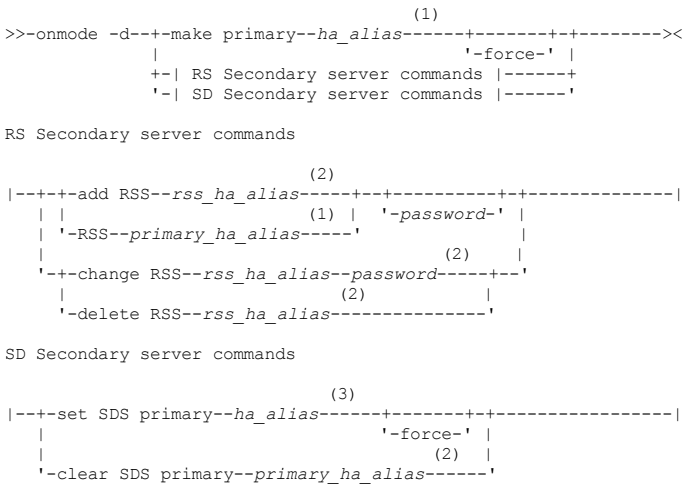
Related information:
Connection information set in the HA_ALIAS configuration parameter

onmode -d: Set High Availability server characteristics

Syntax:



Notes:

1. Run on secondary server only.
2. Run on primary server only.
3. Run on primary server or secondary server.

Element	Purpose	Key Considerations
-d	Used to create, modify, or delete secondary servers in high-availability configurations	
add RSS	Adds an RS secondary server	This command should be run on the primary database server.
rss_ha_alias	Identifies the RS secondary database server's high-availability alias.	The value can be an HA_ALIAS value or an ER group name.
password	Specifies the secondary server password	The password is used only during the first connection attempt. After the primary and secondary server have connected, the password cannot be changed.
RSS	Sets an RS secondary server type	This command should be run on the secondary database server.
pri_ha_alias	Identifies the name of the primary server	
change RSS	Change an RS secondary server	This command should be run on the primary database server.
delete RSS	Removes an RS secondary server definition	This command should be run on the primary database server.
set SDS primary	Defines the server as a shared disk primary server	
ha_alias	The high-availability alias of the database server	When used with **set SDS** or **make primary**, this is the name of the server whose role is changing.
force	Used to force a change	If the **force** option is specified, the operation is performed without requiring that the secondary server be connected to the current primary server. If the **force** option is not specified, the operation must be coordinated with the current primary server. The **force** option should be used only when the DBA is certain that the current primary server is not active; otherwise, the shared disk subsystem can become corrupted.
clear SDS primary	Disables the shared disk environment. The server name specified no longer acts as an SD primary server	
make primary	Creates a primary server	The **make primary** command can be issued on any type of secondary server, including HDR secondary, RS secondary, and SD secondary servers. If **make primary** is run on: • HDR Secondary: The current primary server is shut down and the secondary is made the primary. • RS secondary: The server is changed to a standard server. • SD secondary: The server is made the new primary server.

You can also set data replication characteristics can with SQL administration API *command* equivalents. For more information see SQL Administration API Overview and the *IBM® Informix® Administrator's Guide*.

For other **onmode -d** information, see onmode -d: Set data-replication types and onmode -d command: Replicate an index with data-replication.

onmode -d: Set data-replication types

DBSERVERALIASES configuration parameter
DBSERVERNAME configuration parameter
HA_ALIAS configuration parameter
onmode -d command: Replicate an index with data-replication

onmode -d command: Replicate an index with data-replication

Syntax:

```
>>-onmode-- -d--+-idxauto--+-on--+------------------------+----><
               |            '-off-'                       |
               '-index--database:-+--------+-table#index-'
                                  '-owner.-'
```

Element	Purpose	Key considerations
-d	Specifies how indexes are replicated to a High-Availability Data-Replication (HDR) secondary server when an index on the secondary server becomes corrupt	You can use the **onmode -d idxauto** and **onmode -d index** commands while the server is in online mode.
idxauto	Enables automatic index replication when an index on a secondary server becomes corrupt	Use the **onmode -d idxauto** command to overwrite the value of the DRIDXAUTO configuration parameter within a session.
index	Replicates an index from a primary to a secondary server	If you detect a corrupt index on a secondary server, use the **onmode -d index** command to start replication of the index from the primary to the secondary server.
database	Specifies the database containing the index to replicate	Syntax must conform to the Identifier segment; see the *IBM® Informix® Administrator's Guide*.
index	Specifies the name of the index to replicate	Index must exist on table and in database specified. Syntax must conform to the Identifier segment; see the *IBM Informix Administrator's Guide*.
owner	Specifies the owner of a table	You must specify the current owner of the table. Syntax must conform to the Table Name segment; see the *IBM Informix Administrator's Guide*.
table	Specifies the name of the table on which the index is based	Syntax must conform to the Table Name segment; see the *IBM Informix Administrator's Guide*.

The **onmode -d idxauto** and the **onmode -d index** commands provide methods to replicate an index to a secondary server containing a corrupted index. The base table will be locked during the transfer of an index. The alternative to using these options is to drop and rebuild the corrupt index on the primary server.

In the case of a fragmented index with one corrupt fragment, the **onmode -d idxauto** command only transfers the single affected fragment, whereas the **onmode -d index** command transfers the whole index.

Related reference:
DRIDXAUTO configuration parameter
ha set idxauto argument: Replicate indexes to secondary servers (SQL administration API)

HA_ALIAS configuration parameter

onmode -D, -M, -Q, -S: Change decision-support parameters

Syntax:

```
>>-onmode--+- -D--max_priority-+-------------------------------><
           +- -M--kilobytes----+
           +- -Q--queries------+
           '- -S--scans--------'
```

Element	Purpose	Key considerations
-D *max_priority*	Changes the value of MAX_PDQPRIORITY	This value must be an unsigned integer between 0 and 100. Specify *max_priority* as a factor to temper user requests for PDQ resources. For information on parameters used for controlling PDQ, see MAX_PDQPRIORITY configuration parameter and the *IBM® Informix Performance Guide*.

Element	Purpose	Key considerations
-M *kilobytes*	Changes the value of DS_TOTAL_MEMORY	This value has a platform-dependent upper limit. If you enter a very large value and that value is too large for your platform, you will receive a message that gives you the range of values for your platform. Specify *kilobytes* for the maximum amount of memory available for parallel queries. For more information, see DS_TOTAL_MEMORY configuration parameter and the *IBM Informix Performance Guide*.
-Q *queries*	Changes the value of DS_MAX_QUERIES	This value must be an unsigned integer between 1 and 8,388,608. Specify *queries* for the maximum number of concurrently executing parallel queries. For information on parameters used for controlling PDQ, see DS_MAX_QUERIES configuration parameter and the *IBM Informix Performance Guide*.
-S *scans*	Changes the value of DS_MAX_SCANS	This value must be an unsigned integer between 10 and 1,048,576. Specify *scans* for the maximum number of concurrently executing parallel scans. For information on parameters used for controlling PDQ, see DS_MAX_SCANS configuration parameter and the *IBM Informix Performance Guide*.

These options allow you to change configuration parameters while the database server is online. The new values affect only the current instance of the database server; the values are not recorded in the ONCONFIG file. If you shut down and restart the database server, the values of the parameters revert to the values in the ONCONFIG file. For more information about these configuration parameters, see Database configuration parameters.

To check the current values for the MAX_PDQPRIORITY, DS_TOTAL_MEMORY, DS_MAX_SCANS, DS_MAX_QUERIES, and the DS_NONPDQ_QUERY_MEM configuration parameters, use **onstat -g mgm**. See onstat -g mgm command: Print MGM resource information.

This command has an equivalent SQL administration API function.

Related reference:

onmode and Q arguments: Set maximum number for decision-support queries (SQL administration API)
onmode and S arguments: Set maximum number of decision-support scans (SQL administration API)

onmode -e: Change usage of the SQL statement cache

Syntax:

```
>>-onmode-- -e--mode-------------------------------------------><
```

Element	Purpose	Key considerations
onmode -e `ENABLE`	Enables the SQL statement cache. For more information, see the material on improving query performance in the *IBM® Informix® Performance Guide*.	User sessions use the cache only when they perform either of the following actions: • Set the environment variable STMT_CACHE to `1` • Execute the SQL statement SET STATEMENT CACHE ON
onmode -e `FLUSH`	Flushes the statements that are not in use from the SQL statement cache	The **onstat -g ssc ref_cnt** field shows 0.
onmode -e `OFF`	Turns off the SQL statement cache	No statements are cached.
onmode -e `ON`	Turns on the SQL statement cache	All statements are cached unless the user turns it off with one of the following actions: • Set the environment variable STMT_CACHE to `0` • Execute the SQL statement SET STATEMENT CACHE OFF

The **onmode -e** changes are in effect for the current database server session only. When you restart the database server, it uses the default STMT_CACHE parameter value in the ONCONFIG file.

This command has an equivalent SQL administration API function.

Related reference:
STMT_CACHE configuration parameter
onmode and e arguments: Change usage of the SQL statement cache (SQL administration API)

onmode -F: Free unused memory segments

Use the **onmode -F** command to free shared-memory segments that are unavailable or no longer needed for a process

Syntax:

```
>>-onmode-- -F-------------------------------------------------><
```

Element	Purpose	Key considerations
-F	Frees unused memory segments	None.

When you execute **onmode -F**, the memory manager examines each memory pool for unused memory. When the memory manager locates blocks of unused memory, it immediately frees the memory. After the memory manager checks each memory pool, it begins checking memory segments and frees any that the database server no longer needs.

It is recommended that you run **onmode -F** from an operating-system scheduling facility regularly and after the database server performs any function that creates additional memory segments, including large index builds, sorts, or backups.

Running **onmode -F** causes a significant degradation of performance for any users that are active when you execute the utility. Although the execution time is brief (1 to 2 seconds), degradation for a single-user database server can reach 100 percent. Systems with multiple CPU virtual processors experience proportionately less degradation.

To confirm that **onmode** freed unused memory, check your message log. If the memory manager frees one or more segments, it displays a message that indicates how many segments and bytes of memory were freed.

This command has an equivalent SQL administration API function.

Related reference:
onmode and F arguments: Free unused memory segments (SQL administration API)

onmode -h: Update sqlhosts caches

Syntax

```
>>-onmode-- -h--+-------+--><
               +-force-+
```

Element	Purpose	Key considerations
-h	Allows you to update sqlhosts caches.	The database server maintains a hierarchy of sqlhosts caches. There is a cache of sqlhosts entries for each session. In addition, there exists a global cache of the sqlhosts entries which can be enabled and disabled by the use of the sqlhosts argument of the NS_CACHE configuration parameter. The global sqlhosts cache entries will be reloaded when this cache is enabled and the last modification time of the sqlhosts file is newer than the cache read time of the entry.
-force	This optional argument allows you to trigger the sqlhosts caches unconditionally.	The sqlhosts caches will be reloaded unconditionally.

This command has an equivalent SQL administration API function. For more information, see onmode and h arguments: Update sqlhosts caches (SQL administration API)

onmode -I: Control diagnostics collection

Use the **onmode -I** option to start and stop diagnostics collection.

When you encounter an error, you can specify the **onmode -I** *iserrno* option to start collecting diagnostics information. You can also specify the session ID to collect information for only specific session.

To stop the diagnostics collection, use the onmode **-I** option without any other parameters.

```
>>-onmode-- -I--+----------------------+-----------------------><
                |          .-,-------. |
                |          V         | |
                '-iserrno----+-----+-+-'
                             '-sid-'
```

Element	Purpose	Key Considerations
iserrno	Message number of the error that you want to collect diagnostic information for.	None.
sid	Session ID of the session that you want to collect diagnostic information for.	None.

The diagnostics collection procedures are described in the *IBM® Informix® Administrator's Guide*.

onmode -k, -m, -s, -u, -j: Change database server mode

Syntax:

```
>>-onmode--+- -k-+-----------------------------------------><
           +- -m-+
           +- -s-+
           +- -u-+
           '- -j-'
```

Element	Purpose	Key Considerations
-k	Takes the database server to offline mode and removes shared memory	To reinitialize shared memory, shut down and restart the database server. Taking the Database Server to Offline Mode with the -k Option.
-m	Takes the database server from quiescent or administration mode to online mode	See Bringing the Database Server Online with the -m Option.
-s	Shuts down the database server gracefully	Users who are using the database server are allowed to finish before the database server comes to quiescent mode, but no new connections are allowed. When all processing is finished, **-s** takes the database server to quiescent mode. The **-s** option leaves shared memory intact. See Shutting Down the Database Server Gracefully with the -s Option.
-u	Shuts down the database server immediately	This option brings the database server to quiescent mode without waiting for users to finish their sessions. Their current transactions are rolled back, and their sessions are terminated. See Shutting Down the Database Server Immediately with the -u Option.
-j	Puts the database server into administration mode	This option brings the database server to administration mode, allowing the **informix** user all functions including the issuance of SQL and DDL commands. The **-j -U** option enables the DBSA to designate specific users (in addition to the **informix** user) to access the database server. See your *IBM® Informix® Administrator's Guide*.

The following sections describe the options that take the database server from one mode to another.

- Taking the Database Server to Offline Mode with the -k Option
  The **onmode -k** option takes the database server to offline mode and removes database server shared memory.
- Bringing the Database Server Online with the -m Option
- Shutting Down the Database Server Gracefully with the -s Option
- Shutting Down the Database Server Immediately with the -u Option
- Changing the Database Server to Administration Mode with the -j Option

Related reference:
onmode and j arguments: Switch the database server to administration mode (SQL administration API)
onmode and m arguments: Switch to multi-user mode (SQL administration API)

Taking the Database Server to Offline Mode with the -k Option

The **onmode -k** option takes the database server to offline mode and removes database server shared memory.

A prompt asks for confirmation. Another prompt asks for confirmation to kill user threads before the database server comes offline. If you want to eliminate these prompts, execute the **-y** option with the **-s** option.

This option does not kill all client sessions. Use the **-u** option to avoid hanging client sessions or virtual server processes.
Important: When you use the **onmode -k** command to shut down the database server, utilities that are waiting for a user response might not terminate. For example, **ontape** might be waiting for another tape, **onstat -i** might be waiting for a user response, or **onspaces** might be waiting for **y** or **n** to continue. If this problem occurs, use **onmode -uk** or **-uky** instead to roll back work before removing shared memory. For more information, see the descriptions of other options on this page.
Related reference:
The onclean utility
The onshutdown script

Bringing the Database Server Online with the -m Option

The **-m** option brings the database server online from quiescent mode.

Shutting Down the Database Server Gracefully with the -s Option

The **-s** option causes a graceful shutdown. Users who are using the database server are allowed to finish before the database server comes to quiescent mode, but no new connections are allowed. When all processing is finished, **-s** takes the database server to quiescent mode. The **-s** option leaves shared memory intact.

A prompt asks for confirmation. If you want to eliminate this prompt, execute the **-y** option with the **-s** option.

Shutting Down the Database Server Immediately with the -u Option

The **-u** option causes immediate shutdown. This option brings the database server to quiescent mode without waiting for users to finish their sessions. Their current transactions are rolled back, and their sessions are terminated.

A prompt asks for confirmation. Another prompt asks for confirmation to kill user threads before the database server comes to quiescent mode. If you want to eliminate these prompts, execute the **-y** option with the **-s** option.

Changing the Database Server to Administration Mode with the -j Option

The **-j** option puts the database server into the administration mode and allows only the DBSA group and the user **informix** to connect to the server. The **-j** option allows a DBSA to have the server in a fully functional mode to perform maintenance.

The **-j -U** option enables the DBSA to grant individual users access to the database server in administration mode. Once connected, these individual users can execute any SQL or DDL command. When the server is changed to administration mode, all sessions for users other than user **informix**, the DBSA group users, and those identified in the **onmode -j -U** command lose their database server connection.

The following example enables three individual users to connect to the database server and have database server access until the database server mode changes to offline, quiescent or online mode:

```
onmode -j -U karin,sarah,andrew
```

Access for individual users can also be removed by executing **onmode -j -U** and removing their name from the new list of names in the command. For example, in the following commands, the first command grants only Karin access, the second command grants Karin and Sarah access, and the third command grants only Sarah access (and removes access from Karin).

```
onmode -j -U karin
onmode -j -U karin,sarah
onmode -j -U sarah
```

To allow user **informix** and the DBSA group user to retain their database server access in administration mode and remove all single users from accessing the database server, use the following command:

```
onmode -j -U ' '
```

For information on designating single users in administration mode using a configuration parameter, see ADMIN_MODE_USERS configuration parameter

Related reference:
ADMIN_MODE_USERS configuration parameter

onmode -l: Switch the logical-log file

Syntax:

```
>>-onmode-- -l-----------------------------------------------><
```

Element	Purpose	Key considerations
-l	Switches the current logical-log file to the next logical-log file	You must use **onmode** to switch to the next logical-log file. For information on switching to the next logical-log file, see the chapter on managing logical-log files in the *IBM® Informix® Administrator's Guide*.

This command has an equivalent SQL administration API function.

Related reference:
onmode and l arguments: Switch to the next logical log (SQL administration API)

onmode -n, -r: Change shared-memory residency

Syntax:

```
>>-onmode--+- -n-+-----------------------------------------><
           '- -r-'
```

Element	Purpose	Key considerations
-n	Ends forced residency of the resident portion of shared memory	This command does not affect the value of RESIDENT, the forced-residency parameter in the ONCONFIG file.
-r	Starts forced residency of the resident portion of shared memory	This command does not affect the value of RESIDENT, the forced-memory parameter in the ONCONFIG file.

Important: Set the RESIDENT parameter to 1 before you use the **onmode -r** or **-n** options.
For information on using the forced-residency parameter to turn residency on or off for the next time that you restart the database server, see the chapter on managing shared memory in the *IBM® Informix® Administrator's Guide*.

This command has an equivalent SQL administration API function.

Related reference:
RESIDENT configuration parameter
onmode and n arguments: Unlock resident memory (SQL administration API)
onmode and r arguments: Force residency of shared memory (SQL administration API)

onmode -O: Override ONDBSPACEDOWN WAIT mode

Syntax:

```
>>-onmode-- -O-------------------------------------------------><
```

Element	Purpose	Key considerations
-O	Overrides the WAIT mode of the ONDBSPACEDOWN configuration parameter	None.

Use the **onmode -O** option only in the following circumstances:

- ONDBSPACEDOWN is set to WAIT.
- A disabling I/O error occurs that causes the database server to block all updating threads.
- You cannot or do not want to correct the problem that caused the disabling I/O error.
- You want the database server to mark the disabled dbspace as down and continue processing.

When you execute this option, the database server marks the dbspace responsible for the disabling I/O error as down, completes a checkpoint, and releases blocked threads. Then **onmode** prompts you with the following message:

```
This will render any dbspaces which have incurred disabling I/O errors unusable
and require them to be restored from an archive.
Do you wish to continue?(y/n)
```

If **onmode** does not find any disabling I/O errors on noncritical dbspaces when you run the -O option, it notifies you with the following message:

```
There have been no disabling I/O errors on any noncritical dbspaces.
```

This command has an equivalent SQL administration API function.

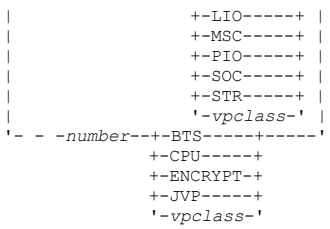
Related reference:
ONDBSPACEDOWN configuration parameter
onmode and O arguments: Mark a disabled dbspace as down (SQL administration API)

onmode -p: Add or drop virtual processors

Use the **onmode -p** command to dynamically add or drop virtual processors for the database server instance. The **onmode -p** command does not update the onconfig file.

Syntax:

```
>>-onmode-- -p--+-+----+--number--+-ADT-----+-+----------------><
               | '- +-'           +-AIO-----+ |
               |                  +-BTS-----+ |
               |                  +-CPU-----+ |
               |                  +-DWAVP---+ |
               |                  +-ENCRYPT-+ |
               |                  +-JVP-----+ |
```



Element	Purpose	Key Considerations
-p *number*	Adds or drops virtual processors. The *number* argument indicates the number of virtual processors to add or drop If this value is a negative integer, processors are dropped. If this value is a positive integer, processors are added.	You can use the **-p** option only when the database server is in online mode, and you can add to only one class of virtual processors at a time. For more details, see Rules for adding and dropping virtual processors. If you are dropping virtual processors, the maximum cannot exceed the actual number of processors of the specified type. If you are adding virtual processors, the maximum number depends on the operating system. For more information, see the chapter on using virtual processors in the *IBM® Informix Administrator's Guide*.
ADT	Runs auditing processes	The database server starts one virtual processor in the audit class when you turn on audit mode by setting the ADTMODE parameter in the ONCONFIG file.
AIO	Performs nonlogging disk I/O to cooked disk spaces	Also performs nonlogging I/O to raw disk spaces if kernel asynchronous I/O (KAIO) is not used.
BTS	Run basic text search index operations and queries.	BTS virtual processors are non-yielding. Specify more BTS virtual processors if you want multiple basic text search queries to be run simultaneously. Use the VPCLASS parameter in the onconfig file to create at least one permanent BTS virtual processor. For more information on basic text search queries, see the *IBM Informix Database Extensions User's Guide*.
CPU	Runs all session threads and some system threads	It is recommended that the number of CPU VPs not be greater than the number of physical processors. If KAIO is used, performs I/O to raw disk spaces, including I/O to physical and logical logs. Runs thread for KAIO where available or a single poll thread. The database server uses the number of CPU VPs to allocate resources for parallel database queries (PDQ). If you drop CPU VPs, your queries will run significantly slower. The **Reinit** field of the **onstat -g mgm** output displays information on the number of queries that are waiting for running queries to complete after an **onmode -p** command. Also see the *IBM Informix Performance Guide*.
DWAVP	Runs the administrative functions and procedures for Informix® Warehouse Accelerator on a database server that is connected to Informix Warehouse Accelerator	A single DWAVP can process most Informix Warehouse Accelerator operations without delay. However, in systems with significant activity, you can define a maximum of two DWAVP virtual processors to avoid the delay of other administrative commands while data marts are loading.
ENCRYPT	Executes column-level encryption and decryption routines	Specify more ENCRYPT virtual processors if you have multiple encrypted columns.
JVP	Executes Java™ user-defined routines in the Java Virtual Machine (JVM)	Specify more JVPs if you are running many Java UDRs.
LIO	Writes to the logical-log files if they are in cooked disk space	Use two LIO virtual processors only if the logical logs are in mirrored dbspaces. The database server allows a maximum of two LIO virtual processors.
MSC	Manages requests for system calls that require a large stack	Used for miscellaneous internal tasks.
PIO	Writes to the physical log if it is in cooked disk space	Use two PIO virtual processors only if the physical log is in a mirrored dbspace. The database server allows a maximum of two PIO virtual processors.
SOC	Uses sockets to perform network communications	You can use the SOC virtual processor only if the database server is configured for network connections through sockets.
STR	Performs stream pipe connections	
vpclass	Names a user-defined virtual processor class	Use the VPCLASS parameter in the onconfig to define the user-defined virtual-processor class. Specify more user-defined virtual processors if you are running many UDRs. On Windows, you can have only one user-defined virtual processor class at a time. Omit the *number* parameter in the **onmode -p** *vpclass* command. For more information on extension classes, see VPCLASS configuration parameter.

- Rules for adding and dropping virtual processors
  You can add or drop virtual processors.
- Monitoring poll threads with the onstat utility

Related reference:
onmode and p arguments: Add or remove virtual processors (SQL administration API)
VPCLASS configuration parameter

Rules for adding and dropping virtual processors

You can add or drop virtual processors.

The following rules apply:

- You cannot drop the final virtual processor. At least one virtual processor must remain.
- You cannot add or drop ADM or OPT.
- **Windows Only:** You can add a supported virtual processor of any class, but you cannot drop virtual processors.

These are the virtual processors that you can add or drop:

Virtual processor name	Add	Drop
ADT	Yes	No
AIO	Yes	No
BTS	Yes	Yes
CPU	Yes	Yes
ENCRYPT	Yes	Yes
JVP	Yes	Yes
LIO	Yes[1]	No
MSC	Yes	No
PIO	Yes[1]	No
SOC	Yes	No
STR	Yes	No
vpclass	Yes	Yes

Table note:

1. You can add one more virtual processor.

Monitoring poll threads with the onstat utility

While the database server is online, you cannot drop a CPU virtual processor that is running a poll thread. To identify poll threads that run on CPU virtual processors, use the following command:

```
onstat -g ath | grep 'cpu.*poll'
```

The following **onstat -g ath** output shows two CPU virtual processors with poll threads. In this situation, you cannot drop to fewer than two CPU virtual processors.

```
tid  tcb      rstcb  prty  status    vp-class  name

8     a362b90  0     2     running   1cpu      tlitcppoll
9     a36e8e0  0     2     cond wait arrived   3cpu
```

The `status` field contains information, such as `running`, `cond wait`, `IO Idle`, `IO Idle`, `sleeping secs: number_of_seconds`, or `sleeping forever`. To improve performance, you can remove or reduce the number of threads that are identified as `sleeping forever`.

For more information on the types of virtual processors, see the chapter on virtual processors and threads in the *IBM® Informix® Administrator's Guide*.

This command has an equivalent SQL administration API function.

onmode -P: Start, stop, or restart a listen thread dynamically

Use the **onmode -P** command to start, stop, or restart an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.

Syntax:

```
>>-onmode-- -P--+-start---+--server_name-----------------------><
               +-stop----+
               '-restart-'
```

Element	Purpose	Key Considerations
start	Start a new listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.	The definition of the listen thread must exist in the **sqlhosts** file for the server. If the definition of the listen thread does not exist in the **sqlhosts** file, you must add it before you can start the listen thread dynamically.

Element	Purpose	Key Considerations
stop	Stop an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.	The definition of the listen thread must exist in the **sqlhosts** file for the server.
restart	Stop and start an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.	The definition of the listen thread must exist in the **sqlhosts** file for the server.
server_name	The name of the database server on which you want to start, stop, or restart a listen thread.	

These commands do not update the **sqlhosts** file.

These commands are equivalent to the SQL administration API functions that have start listen, stop listen, or restart listen arguments.

Example

The following command stops and then starts a listen thread for a server named **ids_serv1**:

```
onmode -P restart ids_serv1
```

Related reference:
start listen argument: Start a listen thread dynamically (SQL administration API)
stop listen argument: Stop a listen thread dynamically (SQL administration API)
restart listen argument: Stop and start a listen thread dynamically (SQL administration API)

onmode -R: Regenerate .infos.dbservername File

The database server creates the .infos.*dbservername* file when you initialize shared memory and removes the file when you take the database server offline. This file is in the $INFORMIXDIR/etc or %INFORMIXDIR%\etc directory. The name of this file is derived from the DBSERVERNAME parameter in the ONCONFIG configuration file.

The database server uses information from the .infos.*dbservername* file when it accesses utilities. If the file is accidentally deleted, you must either re-create the file or shut down and restart the database server.

Syntax:

```
>>-onmode-- -R-------------------------------------------------><
```

Element	Purpose	Key Considerations
-R	Re-creates the .infos.*dbservername* file	Before you use the **-R** option, set the INFORMIXSERVER environment variable to match the DBSERVERNAME parameter from the ONCONFIG file. Do not use the **-R** option if the INFORMIXSERVER environment variable is set to one of the DBSERVERALIASES names.

onmode -W: Change settings for the SQL statement cache

Syntax:

```
>>-onmode-- -W--+-STMT_CACHE_HITS--hits-----+------------------><
               '-STMT_CACHE_NOLIMIT--value-'
```

Element	Purpose	Key Considerations
STMT_CACHE_HITS *hits*	Specifies the number of hits (references) to a statement before it is fully inserted in the SQL statement cache Set ***hits*** to 1 or more to exclude ad hoc queries from entering the cache.	You can only increase or reset the value of STMT_CACHE_HITS. The new value displays in the **#hits** field of the **onstat -g ssc** output. If ***hits*** = 0, the database server inserts all qualified statements and its memory structures in the cache. If ***hits*** > 0 and the number of times the SQL statement has been executed is less than STMT_CACHE_HITS, the database server inserts *key-only* entries in the cache. It inserts qualified statements in the cache after the specified number of hits have been made to the statement. **ONCONFIG** Parameter: STMT_CACHE_HITS
STMT_CACHE_NOLIMIT *value*	Controls whether statements are inserted in the SQL statement cache.	If *value* = 0, the database server inserts no statements in the cache. If *value* = 1, the database server always inserts statements in the cache. If none of the queries are shared, turn off STMT_CACHE_NOLIMIT to prevent the database server from allocating a large amount of memory for the cache.**ONCONFIG** Parameter: STMT_CACHE_NOLIMIT

- SQL statement cache examples

Related reference:
STMT_CACHE_HITS configuration parameter
STMT_CACHE_NOLIMIT configuration parameter
onmode and W arguments: Reset statement cache attributes (SQL administration API)

SQL statement cache examples

The following are examples of **onmode -W** commands for changing SQL statement cache (SSC) settings. The changes are in effect for the current database server session only and do not change the ONCONFIG values. When you restart the database server, it uses the default SSC settings, if not specified in the ONCONFIG file, or the ONCONFIG settings. To make the changes permanent, set the appropriate configuration parameter.

```
onmode -W STMT_CACHE_HITS 2  # number of hits before statement is
     # inserted into SSC
onmode -W STMT_CACHE_NOLIMIT 1  # always insert statements into
     # the cache
```

This command has an equivalent SQL administration API function.

onmode -we: Export a file that contains current configuration parameters

Use the **onmode -we** command to create and export a configuration file that is a snapshot of your current configuration parameters.

Syntax:

```
>>-onmode-- -we--path_name-------------------------------------><
```

Element	Description	Key Considerations
path_name	The full or relative path name of the configuration file.	Do not add an extension.

Usage

The **onmode -we** command automatically creates an ASCII file, assigning it the name that you specified in the command. The format of the file is the same as the format of the onconfig.std file.

If you changed any values dynamically during the current session, the exported file contains the changed values instead of the values that are permanently saved in the onconfig file.

After you export the configuration file, you can import it and use it as your configuration file.

If run the **onmode -we** command and specify a file that was previously exported, the command exports the new version of the file, overwriting the previous exported file.

The **onmode -we** command is equivalent to the SQL administration API function that has the onmode and export arguments.

Examples

The following command exports all configuration parameters and their current values to the onconfig3 file in the `/tmp` directory:

```
onmode -we /tmp/onconfig3
```

Related tasks:
Modifying the onconfig file
Related reference:
onmode -wi: Import a configuration parameter file
export config argument: Export configuration parameter values (SQL administration API)

onmode -wf, -wm: Dynamically change certain configuration parameters

Use the **onmode -wf** or **onmode -wm** command to dynamically change specific configuration parameters.

Syntax:

```
>>-onmode--+- -wf--config_param=value-+------------------------><
```

```
'- -wm--config_param=value-'
```

Element	Purpose	Key considerations
-wf	Updates the value of the specified configuration parameter in the onconfig file.	The DBA user must have write permission for the directory that contains the onconfig file.
-wm	Dynamically sets the value of the specified configuration parameter in memory.	The specified *value* is not preserved when the server is restarted.
config_param=*value*	Specifies the configuration parameter and its new value.	See Database configuration parameters.

To see a list of configuration parameters that you can tune dynamically with an **onmode -wm** or **-wf command**, run the **onstat -g cfg tunable** command.

The **onmode -wf** and **onmode -wm** commands have equivalent SQL administration API functions.

- onmode -wm: Change LRU tuning status
  You can use the **onmode -wm** option to change the LRU tuning status without updating the onconfig file.

Related tasks:
Modifying the onconfig file
Related reference:
onstat -g cfg command: Print the current values of configuration parameters
onmode and wf arguments: Permanently update a configuration parameter (SQL administration API)
onmode and wm arguments: Temporarily update a configuration parameter (SQL administration API)
set onconfig memory argument: Temporarily change a configuration parameter (SQL administration API)
set onconfig permanent argument: Permanently change a configuration parameter (SQL administration API)

onmode -wm: Change LRU tuning status

You can use the **onmode -wm** option to change the LRU tuning status without updating the onconfig file.

Syntax:

```
>>-onmode-- -wm--AUTO_LRU_TUNING----+-0-+----------------------><
                                    '-1-'
```

Element	Purpose	Key considerations
-wm	Dynamically sets the value of the specified configuration parameter for the current session.	None.
0	Turns off automatic LRU tuning for the current session.	None.
1	Turns on automatic LRU tuning for the current session.	None.

This command has an equivalent SQL administration API function.

Related reference:
onmode, wm, and AUTO_LRU_TUNING arguments: Change LRU tuning status (SQL administration API)

onmode -wi: Import a configuration parameter file

Use the **onmode -wi** command to import a file that contains new values for multiple configuration parameters. If the parameters are tunable, which means they can be updated individually with an **onmode -wm** command, the database server applies the new values.

Syntax:

```
>>-onmode-- -wi--path_name--------------------------------------><
```

Element	Purpose	Key Considerations
path_name	The full or relative path name of the previously exported configuration file.	

Usage

Importing a configuration file with **onmode -wi** is often faster and more convenient than running individual **onmode -wm** commands on multiple tunable configuration parameters.

The import operation ignores the configuration parameters in the file that are not tunable. The operation also ignores new parameter values that match the values that are currently used by the instance.

After you import the file, you can modify the values of the imported configuration parameters.

An import operation changes only the values of configuration parameters that are in memory. The operation does not affect the values in the $INFORMIXDIR/etc/$ONCONFIG file.

The **onmode -wi** command is equivalent to the SQL administration API functions that have onmode and wi arguments or the import argument.

Example

The following command imports the configuration parameters that are in a file named onconfig3 in the /tmp directory:

```
onmode -wi /tmp/onconfig3
```

Related tasks:
Modifying the onconfig file
Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters
onmode -we: Export a file that contains current configuration parameters
import config argument: Import configuration parameter values (SQL administration API)

onmode -Y: Dynamically change SET EXPLAIN

Syntax:

```
>>-onmode-- -Y--session_id--+-0--------------------+----------><
                           '-+-2-+--+-----------+-'
                             '-1-'  '-file_name-'
```

Element	Purpose	Key considerations
file_name	The explain output file name.	If the file's absolute path is not included, the example output file is created in the default example output file location. If the file exists, explain output is appended to it. If a file exists from the SET EXPLAIN statement, that file is not used until dynamic explain is turned off.
session_id	Identifies the specific session.	None.
-Y	Dynamically change the value of the SET EXPLAIN statement.	None.

You can use the SET EXPLAIN statement to display the query plan of the optimizer, an estimate of the number of rows returned, and the relative cost of the query. When you use the **onmode -Y** command to turn on SET EXPLAIN, the output is displayed in the explain output file.

The **onmode -Y** command dynamically changes the value of the SET EXPLAIN statement for an individual session. The following invocations are valid with this command:

Invocation	Explanation
`onmode -Y session_id 2`	Turns SET EXPLAIN on for *session_id*
`onmode -Y session_id 1`	Turns SET EXPLAIN on for *session_id* and displays the query statistics section in the explain output file
`onmode -Y session_id 1 /tmp/myexplain.out`	Turns SET EXPLAIN on for *session_id* and writes explain output to /tmp/myexplain.out.
`onmode -Y session_id 0`	Turns SET EXPLAIN off for *session_id*

This command has an equivalent SQL administration API function.

Related reference:
EXPLAIN_STAT configuration parameter
onmode and Y arguments: Change query plan measurements for a session (SQL administration API)
Related information:
SET EXPLAIN statement
Using the FILE TO option
Default name and location of the explain output file on UNIX
Default name and location of the output file on Windows
Report that shows the query plan chosen by the optimizer
The explain output file
Query statistics section provides performance debugging information

onmode -z: Kill a database server session

Syntax:

```
>>-onmode-- -z--sid-------------------------------------------><
```

Element	Purpose	Key considerations
-z *sid*	Kills the session that you specify in *sid*	This value must be an unsigned integer greater than 0 and must be the session identification number of a currently running session.

To use the **-z** option, first obtain the session identification (*sessid*) with **onstat -u**, then execute **onmode -z**, substituting the session identification number for *sid*.

When you use **onmode -z**, the database server attempts to kill the specified session. If the database server is successful, it frees any resources that the session holds. If the database server cannot free the resources, it does not kill the session.

If the session does not exit the section or release the latch, the database server administrator can take the database server offline, as described in Taking the Database Server to Offline Mode with the -k Option, to close all sessions.

This command has an equivalent SQL administration API function.

Related reference:
onmode and z arguments: Terminate a user session (SQL administration API)

onmode -Z: Kill a distributed transaction

Syntax:

```
>>-onmode-- -Z--address-----------------------------------------><
```

Element	Purpose	Key considerations
-Z *address*	Kills a distributed transaction associated with the shared-memory address *address*	This argument must be the address of an ongoing distributed transaction that has exceeded the amount of time that TXTIMEOUT specifies. The address must conform to the operating-system-specific rules for addressing shared-memory. (The address is available from **onstat -x** output.) This option is not valid until the amount of time that the ONCONFIG parameter TXTIMEOUT specifies has been exceeded. The **-Z** option should rarely be used and only by an administrator of a database server involved in distributed transactions. For information on initiating independent actions in a two-phase commit protocol, see the chapter on multiphase commit protocols in the *IBM® Informix® Administrator's Guide*.

Distributed transactions provide the ability to query data on different database servers.

Attention: If applications are performing distributed transactions, killing one of the distributed transactions can leave your client/server database system in an inconsistent state. Try to avoid this situation.
This command has an equivalent SQL administration API function.

Related reference:
onmode and Z arguments: Terminate a distributed transaction (SQL administration API)

The onparams Utility

Use the **onparams** utility to add or drop a logical-log file, change physical-log parameters, and add a new buffer pool.

In This Chapter

This chapter shows you how to use the following **onparams** options:

- onparams -a -d dbspace: Add a logical-log file
- onparams -d -l lognum: Drop a logical-log file
- onparams -p: Change physical-log parameters
- onparams -b: Add a buffer pool

Any **onparams** command fails if a storage-space backup is in progress. If you do not use any options, **onparams** returns a usage statement.

You cannot use the **onparams** utility on High-Availability Data Replication (HDR) secondary servers, remote standalone (RS) secondary servers, or shared disk (SD) secondary servers.

You can also use SQL administration API commands that are equivalent to **onparams** commands to add or drop a logical-log file, change physical-log parameters, and add a new buffer pool.

On UNIX, you must be logged in as user **root** or user **informix** to execute **onparams**. Only user **informix** is allowed to execute the SQL administration API *command* strings.

On Windows, you must be a member of the **Informix-Admin** group to execute **onparams**.

- onparams syntax
  Use the **onparams** utility to modify the configuration of logical logs or physical logs.
- onparams -a -d dbspace: Add a logical-log file
- onparams -d -l lognum: Drop a logical-log file
- onparams -p: Change physical-log parameters
- onparams -b: Add a buffer pool
  Use the **onparams -b** command to create a buffer pool that corresponds to the page size of the dbspace.
- Examples of onparams Commands

Related reference:
LOGFILES configuration parameter
RTO_SERVER_RESTART configuration parameter

onparams syntax

Use the **onparams** utility to modify the configuration of logical logs or physical logs.

```
>>-onparams--+-------------------------+--+-----------------+-->
             |                    (1) |  +- -a -d--dbspace-+
             '-|  -FILE option   |-----'  +- -d -l--lognum--+
                                         +- -p-------------+
                                         +- -b-------------+
                                         +- -V-------------+
                                         '- -version-------'
```

Notes:

1. See The -FILE option.

Element	Purpose	Key Considerations
-V	Displays the software version number and the serial number	See Obtaining utility version information.
-version	Displays the build version, host, OS, number and date, as well as the GLS version	See Obtaining utility version information.

onparams -a -d *dbspace*: Add a logical-log file

Syntax:

```
>>-onparams-- -a-- -d--dbspace--+-----------+--+-----+---------><
                               '- -s--size-'  '- -i-'
```

Element	Purpose	Key considerations
-a -d *dbspace*	Adds a logical-log file to the end of the log-file list to the specified *dbspace*	You can add a log file to a dbspace only if the database server has adequate contiguous space. The newly added log files have a status of **A** and are immediately available for use. You can add a log file during a backup. You can have a maximum of 32,767 logical-log files. Use **onstat -l** to view the status of your logical-log files. It is recommended that you take a level-0 backup of the root dbspace and the dbspace that contains the log file as soon as possible. You cannot add a log file to a blobspace or sbspace. Syntax must conform to the Identifier segment; see *IBM® Informix® Guide to SQL: Syntax*.
-i	Inserts the logical-log file after the current log file	Use this option when the Log File Required alarm prompts you to add a logical-log file.
-s *size*	Specifies a size in kilobytes for the new logical-log file	This value must be an unsigned integer greater than or equal to 200 kilobytes If you do not specify a size with the **-s** option, the size of the log file is taken from the value of the LOGSIZE parameter in the ONCONFIG file when database server disk space was initialized. For information on changing LOGSIZE, see the chapter on managing logical-log files in the *IBM Informix Administrator's Guide*.

This command has an equivalent SQL administration API function.

Related reference:
DYNAMIC_LOGS configuration parameter
add log argument: Add a new logical log (SQL administration API)

onparams -d -l *lognum*: Drop a logical-log file

Syntax:

```
>>-onparams-- -d-- -l--lognum--+-----+------------------------><
                               '- -y-'
```

Element	Purpose	Key considerations
-d -l *lognum*	Allows you to drop a logical-log file specified by the log file number	**Restrictions**: The *lognum* value must be an unsigned integer greater than or equal to 0. You can obtain the ***lognum*** from the **number** field of **onstat -l**. The sequence of ***lognum*** might be out of order.
-y	Causes the database server to automatically respond yes to all prompts	None.

Usage

You can only drop one log files at a time.

The database server requires a minimum of three logical-log files at all times. You cannot drop a log if your logical log is composed of only three log files.

Important: Before you can drop any of the first three logical-log files, you must add new logical-log files and run a backup of the logical-log files. The backup must be run using either the **ontape -a** command or the **ontape -c** command. After you add the new logical-log files and run a backup, you can then use **onparams -d -l***lognum* to delete the first three logical-log files.
The status of the log file determines if the log file can be dropped, and the actions taken by the database server when the log file is dropped:

- If you drop a log file that has never been written to, status is newly Added (**A**), the database server deletes the log file and frees the space immediately.
- If you drop a used log file that has a status of User (**U**) or Free (**F**), the database server marks the log file as Deleted (**D**). After you take a level-0 backup of the dbspaces that contain the log files and the root dbspace, the database server deletes the log file and frees the space.
- You cannot drop a log file that is currently in use (**C**) or contains the last checkpoint record (**L**).

This command has an equivalent SQL administration API function.

When you move logical-log files to another dbspace, use the **onparams** commands to add and drop logical-log files. See moving a logical-log file, in the section on managing logical-log files in the *IBM® Informix® Administrator's Guide*.

Related reference:
drop log argument: Drop a logical log (SQL administration API)

onparams -p: Change physical-log parameters

Syntax:

```
>>-onparams-- -p-- -s--size--+---------------+--+-----+---------><
                            '- -d--dbspace-'  '- -y-'
```

Element	Purpose	Key Considerations
-p	Changes the physical log	Whenever you use the **onparams -p** command, you must include the **-s** parameter. Additionally, you can specify the **-d** and **-y** parameters. The database server must be in either administration, online, or quiescent mode to specify the **-p** parameter. The database server does not need to be restarted for the changes take effect.
-s *size*	Changes the size (in kilobytes) of the physical log	This value must be an unsigned integer greater than or equal to 200 kilobytes. Attention: If you move the log to a dbspace without adequate contiguous space or increase the log size beyond the available contiguous space, the operation will fail and the physical log will not change.
-d *dbspace*	Changes the location of the physical log to the specified *dbspace*	The space allocated for the physical log must be contiguous. Syntax must conform to the Identifier segment; see the *IBM® Informix® Guide to SQL: Syntax*.
-y	Causes the database server to automatically respond yes to all prompts	None.

- Backing Up After You Change the Physical-Log Size or Location
- Changing the Size of the Physical Log and Using Non-Default Page Sizes

Related reference:
PHYSFILE configuration parameter
alter plog argument: Change the physical log (SQL administration API)
LOGSIZE configuration parameter

Backing Up After You Change the Physical-Log Size or Location

The database server must be in either the online or quiescent mode when you change the physical log. The database server does not need to be restarted for the changes to take effect.

Create a level-0 backup of the root dbspace immediately after you change the physical-log size or location. This backup is critical for proper recovery of the database server.

Changing the Size of the Physical Log and Using Non-Default Page Sizes

If you use non-default page sizes, you might need to increase the size of your physical log. If you perform many updates to non-default pages you might need a 150 to 200 percent increase of the physical log size. Some experimentation might be needed to tune the physical log. You can adjust the size of the physical log as necessary according to how frequently the filling of the physical log triggers checkpoints.

onparams -b: Add a buffer pool

Use the **onparams -b** command to create a buffer pool that corresponds to the page size of the dbspace.

Syntax

```
>>-onparams-- -b-- -g--size-----------------------------------><
```

Element	Purpose	Key considerations
-b	Creates a buffer pool	You can add a buffer pool while the database server is running.
-g *size*	Specifies the size in KB of the buffer pages to create	The size of the buffer pages must be 2 - 16 KB and a multiple of the default page size.

All other characteristics of the buffer pool that you create are set to the values of the fields in the default line of the BUFFERPOOL configuration parameter.

Each dbspace that you create with a non-default page size must have a corresponding buffer pool with the corresponding page size. If you create a dbspace with a page size that has no buffer pool, the system automatically creates a buffer pool based the fields in the default line of the BUFFERPOOL parameter.

When you add a buffer pool, a new entry for the BUFFERPOOL configuration parameter is added in the onconfig file.

This command has an equivalent SQL administration API function.

Related reference:
add bufferpool argument: Add a buffer pool (SQL administration API)
BUFFERPOOL configuration parameter

Examples of onparams Commands

The following are examples of **onparams** commands:

```
onparams -a -d rootdbs -s 1000  # adds a 1000-KB log file to rootdbs

onparams -a -d rootdbs -i       # inserts the log file after the current log

onparams -d -l 7                # drops log 7

onparams -p -d dbspace1 -s 3000 # resizes and moves physical-log to dbspace1

onparams -b -g 6 -n 3000 -r 2 -x 2.0 -m 1.0 # adds 3000 buffers of size
6K bytes each with 2 LRUS with maximum dirty of 2% and minimum dirty of 1%
```

The onpassword utility

Use the **onpassword** utility to encrypt and decrypt a password file. Connection Manager and Enterprise Replication utilities require a password file to connect to database servers over an untrusted network.

Syntax

```
>>-onpassword-- -k --encryption_key----------------------------->

>--+- -e --text_file--------+---------------------------------><
   '- -d --output_file_name-'
```

Element	Purpose	Key Considerations
-k	Specifies the password key.	
-e	Encrypts an ASCII text file	The password information is encrypted to $INFORMIXDIR/etc/passwd_file
-d	Decrypts the specified encrypted password file.	The passwd_file is decrypted to *$INFORMIXDIR/etc/output_file_name*.
output_file_name	The name of the file that is output by the decryption process.	An encrypted password file that is created on one type of platform is not supported on a different type of platform. You must run the **onpassword** utility on each type of platform, and use the same text file and encryption key.
encryption_key	The encryption key used to encrypt and decrypt password information.	The encryption key can be any sequence of numbers or letters up to 24 bytes in length. To use an encryption key that includes spaces, enclose the encryption key in quotation marks. For example: `"my secret encryption key"`
text_file	The ASCII text file that contains user password information.	The **onpassword** utility uses the following default location: • UNIX: $INFORMIXDIR/tmp • Windows: %INFORMIXDIR%\etc

Usage

Only users logged in as user **informix** have permission to run the **onpassword** utility.

Example 1: Encrypting a password file

To encrypt tmp/my_passwords.txt with **my_secret_encryption_key**, run the following command:

```
onpassword -k my_secret_encryption_key -e my_passwords.txt
```

The password information is encrypted into $INFORMIXDIR/etc/passwd_file.

Example 2: Decrypting an encrypted password file

To decrypt $INFORMIXDIR/etc/passwd_file with **my_secret_encryption_key**, run the following command:

```
onpassword -k my_secret_encryption_key -d my_passwords.txt
```

The password information is decrypted to $INFORMIXDIR/etc/my_passwords.txt.
Related information:
Creating a password file for connecting to database servers on untrusted networks
Modifying encrypted password information

The ifxclone utility

You use the **ifxclone** utility to create a server clone from a snapshot of an existing database server.

Syntax

```
>>-ifxclone--+-| Mandatory parameters |--+-------------------------+-+-><
             |                           '-| Optional parameters |-' |
             '- help ------------------------------------------------'

Mandatory parameters

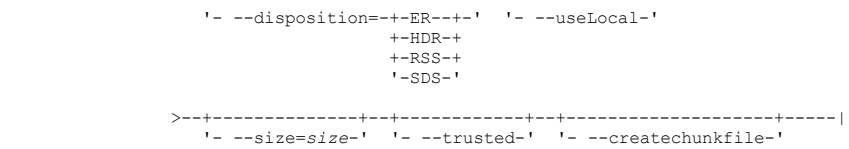
|-- --source=source_name --sourceIP=source_IP --sourcePort=source_port-->

>-- --target=target_name --targetIP=target_IP --targetPort=target_port--|

Optional parameters

   .---------------------------------.
   V                                 |
|----+-------------------------------+-+--+-------------+-------->
     '- --configparmparameter=value-'    '- --autoconf-'

>--+-------------------------+--+-------------+----------------->
```



Element	Purpose	Key Considerations
disposition	Specifies the final disposition of the new server instance.	If the **--disposition** (**-d**) parameter is not specified, a standard server is created.
ER	Specifies that the new server instance is created as a replication server.	
HDR	Specifies that the new server instance is created as an HDR secondary server.	
parameter=value	Specifies an optional configuration parameter and value to set on the target server.	Certain configuration parameters on the source server must match those on the target server. See Prerequisites for cloning an RS secondary server.
RSS	Specifies that the new server instance is created as an remote stand-alone secondary server.	
SDS	Specifies that the new server instance is created as a shared-disk secondary server.	The **ifxclone** utility sets the target server's SDS_PAGING, and SDS_TEMPDBS configuration parameters, but full configuration is outside the scope of the **ifxclone** utility. If **--disposition=SDS** is specified in the command, but **--useLocal** is not, you must set the SD secondary server's ROOTPATH configuration parameter to the same value as the ROOTPATH configuration parameter on the primary server.
size	Specifies the size of the target server. Valid values are `tiny`, `small`, `medium`, and `large`.	If the size parameter is not specified, the size parameters from the source instance are used.
source_name	Specifies the name of the source instance.	The source server must be a primary server and cannot be a secondary server.
source_IP	Specifies the source server instance TCP/IP address.	
source_port	Specifies the TCP/IP port address of the source server instance, or the name of a service associated with the port.	
target_name	Specifies the name of the target server instance.	
target_IP	Specifies the target server instance TCP/IP address.	
target_port	Specifies the TCP/IP port address of the target server instance, or the name of a service associated with the port.	

The following table describes the options of the **ifxclone** utility.

Long Form	Short Form	Meaning
--autoconf	**-a**	Autoconfigures connectivity information between a newly cloned server and the other servers of a high-availability cluster or Enterprise Replication domain. If this option is used to create a replication server, the **--autoconf** option can autoconfigure replication. The **--autoconf** option has the following requirements: • The CDR_AUTO_DISCOVER configuration parameter must be set to `1` on the target server, the source server, and all other cluster or replication servers. • REMOTE_SERVER_CFG must be set on all cluster or replication servers. • The target server's host information must be in the source server's trusted-host file. • If used with the **--disposition=ER** option, and the primary server is part of an Enterprise Replication, all other replication servers in the domain must be active.
--configParm	**-c**	Specifies the name and value of a configuration parameter to set on the target server.
--createchunkfile	**-k**	Automatically creates the same cooked chunk files on the target server as exist on the source server. This option does not create raw chunks. However, if you have raw chunks on the source server and you do not create matching raw chunks on the target server before using this option, the **ifxclone** utility creates cooked chunks on the target server that match the raw chunks on the source server.
--disposition	**-d**	Specifies the disposition of the new server instance.
--help	**-h**	Displays usage information.
--size	**-s**	Specifies the size of the target instance.
--source	**-S**	Specifies the name of the source server instance.
--sourceIP	**-I**	Specifies the TCP/IP address of the source server instance.
--sourcePort	**-P**	Specifies the TCP/IP port address of the source server instance, or the name of a service associated with the port.

Long Form	Short Form	Meaning
--target	**-t**	Specifies the name of the target server instance.
--targetIP	**-i**	Specifies the TCP/IP address of the target server instance.
--targetPort	**-p**	Specifies the TCP/IP port address of the target server instance, or the name of a service associated with the port.
--trusted	**-T**	Specifies that the server is trusted and that it is not necessary to obtain a userid and password to access the server.
--useLocal	**-L**	Specifies that the configuration information contained in the source server onconfig file should be merged with the target server onconfig file. Certain configuration parameters on the source server must match those on the target server. See Prerequisites for all servers.

Usage

Use the **ifxclone** utility to clone a server with minimum setup or configuration, or to quickly add a new node to an existing ER replication domain. When the **ifxclone** utility is run, the majority of the setup information is obtained from the server node that is being cloned. Successfully cloning a server might still require some post-configuration steps to achieve a better running system.

The source server is the server that contains the data you wish to clone. The target server is the server that is to be loaded with data from the source server. You must run the **ifxclone** utility from the target server.

To run the **ifxclone** utility on a UNIX computer, you must run the command on the target server as user **root**, user **informix**, or as a member of the **informix** group. You must also be a DBSA on the source server.

To run the **ifxclone** utility on a Windows computer, you must run the command on the target server as a member of the local administrators group. You must also be a DBSA on the source server and you must belong to the **Informix-Admin** group on the source server.

The **ifxclone** utility uses the onconfig and sqlhosts configuration files from the source server to configure the target server. The **ifxclone** utility also configures some additional configuration settings, but only those required to configure the clone server. The **--autoconf** option provides the additional ability to configure sqlhosts file records, and then propagate sqlhosts and trusted-host file information to the servers of a high-availability cluster or Enterprise Replication domain. The **--createchunkfile** options creates the same cooked chunks and cooked mirror chunks on the target system that are on the source server. The **ifxclone** utility is not meant to configure all of the possible configuration options, but rather to provide enough configuration to clone the source server.

The number of CPU VPs and buffers on the target server can be configured using the size parameter. Table 1 lists the number of CPU VPs and buffer pools created on the target server for each size option. Additional refinement of the generated configuration should be performed after the target system is created. If the size configuration is omitted, the parameter configured on the source server is used.

Table 1. List of size parameter values

Size	Number of CPU VPs	Number of buffers
tiny	1	50,000
small	2	100,000
medium	4	250,000
large	8	500,000

You can use the **-c** option to specify a configuration parameter and its value on the target server. You can also use an existing configuration file. If the target server contains a configuration file that is different than the source server configuration file, the **ifxclone** utility does not overwrite the file but modifies those parameters that must match the source server during the cloning process.

The **--useLocal** parameter is required if the target server is located on the same host machine as the source server.

If the **--useLocal** parameter is specified, the **ifxclone** utility merges the source server onconfig file with the target server onconfig file. The configuration parameters listed in Prerequisites for all servers are overwritten by the **ifxclone** utility and the rest of the parameters are not affected.

If the **--useLocal** parameter is not specified as an input parameter, the **ifxclone** utility uses the source server's onconfig file as the target's onconfig file and uses the server name from the input parameters of the **ifxclone** utility.

If the **--useLocal** parameter is not specified, the **ifxclone** utility updates the sqlhosts file on the host server with the target server entry and copies both entries to the target's sqlhosts file.

The order of precedence of options for the **ifxclone** parameters is as follows:

- The **--configParm** parameter takes precedence over the configuration file on the source server.
- The **--size** parameter takes precedence over merged configuration parameters or the settings in the local configuration file.
- The **--configParm** parameter takes precedence over the **--size** parameter.
- Parameters that must be the same on each server take precedence over all other options.

Prerequisites for all servers

Perform the following prerequisites before cloning a server:

- Hardware and software requirements for the servers are generally the same as those for HDR secondary servers (refer to the machine notes for specific supported platforms).
- Both the source and target servers must be part of a trusted network environment. See Network security files for information about configuring a trusted environment.
- If the disposition of the target server is specified as ER or RSS then you must provide users with connection permission to the **sysadmin** database on the source server. By default, connection permission to the sysadmin database is limited to user **informix**.
- Only one server clone process can occur at a time. Do not start cloning a second server until the first clone process has completed running.

- The source server must have the ENABLE_SNAPSHOT_COPY configuration parameter set to 1 in the onconfig file.
- The target server must not have any old ROOTPATH pages. If the target server has old ROOTPATH pages, create a zero-length ROOTPATH file or set the FULL_DISK_INIT configuration parameter to 1 in the target server's onconfig file.
- The target server must not have any existing storage space encryption keystore or stash files. If you receive an error message that the command failed because of existing keystore and stash files, follow the instructions in the message and rerun the **ifxclone** command.

Archive operations, such as **ontape** and **ON-Bar** commands, are not allowed while cloning a server. Perform your data archive activities before starting to clone a server.

The following environment variables must be set on the target server before cloning a server:

- INFORMIXDIR
- INFORMIXSERVER
- INFORMIXSQLHOSTS
- ONCONFIG

The following configuration parameter values must be identical on both the source and target servers:

- DISK_ENCRYPTION (if the target server is an SD secondary server)
- DRAUTO
- DRINTERVAL
- DRTIMEOUT
- LOGBUFF
- LOGFILES
- LOGSIZE
- LTAPEBLK
- LTAPESIZE
- ROOTNAME
- ROOTSIZE
- PHYSBUFF
- PHYSFILE
- STACKSIZE
- TAPEBLK
- TAPESIZE

If the MIRROR configuration parameter is enabled on the target server, the following configuration parameters also must match between the source and target servers:

- MIRRORPATH
- MIRROROFFSET

The following table shows the valid combinations of the MIRROR configuration parameter on the source and target servers.

Table 2. Valid settings of the MIRROR configuration parameter on source and target servers

MIRROR configuration parameter set on the source server	MIRROR configuration parameter set on the target server	Permitted or not permitted
No	No	Permitted
Yes	Yes	Permitted
Yes	No	Permitted
No	Yes	Not permitted. If this setting is configured, the server issues a warning and disables the MIRROR parameter in the target server onconfig file.

Prerequisites for cloning an RS secondary server

1. Set the following environment variables on the target server:
   - INFORMIXDIR
   - INFORMIXSERVER
   - ONCONFIG
   - INFORMIXSQLHOSTS
2. On the target server, create all of the chunks and mirror chunks that exist on the source server. If the target server is using mirroring, the mirror chunk paths must match those of the source server and the chunks must exist. You can use the **--createchunkfile** option (**-k**) to automatically create cooked chunks on the target server. Follow these steps to create the chunks and (if necessary) mirror chunks for the target server:
   a. On the source server, run the **onstat -d** command to display a list of chunks and mirror chunks:

      ```
      onstat -d
      ```

   b. On the target server, log in as user informix and use the **touch**, **chown**, and **chmod** commands to create the set of chunks and mirror chunks reported by the **onstat -d** command. For example, to create a chunk named /usr/informix/chunks/rootdbs.chunk, follow these steps:

      ```
      $ su informix
      Password:
      $ touch /usr/informix/chunks/rootdbs.chunk
      $ chown informix:informix /usr/informix/chunks/rootdbs.chunk
      $ chmod 660 /usr/informix/chunks/rootdbs.chunk
      ```

   c. Repeat all of the commands in the previous step for each chunk reported by the **onstat -d** command.
3. Run the **ifxclone** utility with the appropriate parameters on the target system.
4. Optionally, create onconfig and sqlhosts files on the target server.

Example 1, Cloning an RS secondary server using the source server configuration

This example shows how to clone a server by using the onconfig and sqlhosts configuration files from the source server.

In this example, omitting the **-L** option causes the **ifxclone** utility to retrieve the necessary configuration information from the source server. The configuration files are used as a template to create the target server configuration. Having the **ifxclone** utility create the configuration files for you saves time and reduces the chance of introducing errors into the configuration files.

The **-k** option creates the necessary cooked chunks on the target server.

For this example, assume that the source server (Amsterdam) has an sqlhosts file configured as follows:

```
#Server   Protocol HostName         Service Group
Amsterdam onsoctcp 192.168.0.1 123     -
```

You also need the name, IP address, and port number of the target server. The following values are used for this example:

- Source server name: Amsterdam
- Source IP address: 192.168.0.1
- Source port: 123
- Target server name: Berlin
- Target IP address: 192.168.0.2
- Target port: 456

1. On the target server, create all of the chunks that exist on the source server. You can use the **--createchunkfile** option (**-k**) to automatically create cooked chunks on the target server. Log-in as user **informix** and use the commands **touch**, **chown**, and **chmod** to create the chunks.
2. On the target server, run the **ifxclone** utility:

   ```
   ifxclone -T -S Amsterdam -I 192.168.0.1 -P 123 -t Berlin
            -i 192.168.0.2 -p 456 -d RSS -k
   ```

   The **ifxclone** utility modifies the sqlhosts file on the source server and creates a copy of the file on the new target server. The sqlhosts file on the target server is the same as the source server:

   ```
   #Server   Protocol HostName         Service Group
   Amsterdam onsoctcp 192.168.0.1 123     -
   Berlin    onsoctcp 192.168.0.2 456
   ```

Example 2, Cloning an RS secondary server by merging the source server configuration

Use the **--useLocal** option to create a clone of a server on a remote host computer: The **--useLocal** option is used to merge the source onconfig file configuration information with the target onconfig file. This option also copies the source sqlhosts file to the target server. The following values are used for this example:

- Source server name: Amsterdam
- Source IP address: 192.168.0.1
- Source port: 123
- Target server name: Berlin
- Target IP address: 192.168.0.2
- Target port: 456

1. Create the onconfig and sqlhosts files and set the environment variables on the target computer.
2. On the target server, create all of the chunks that exist on the source server. You can use the **--createchunkfile** option (**-k**) to automatically create cooked chunks on the target server.Log-in as user **informix** and use the commands **touch**, **chown**, and **chmod** to create the chunks.
3. On the target server, run the **ifxclone** utility:

   ```
   ifxclone -T -L -S Amsterdam -I 192.168.0.1 -P 123 -t Berlin
            -i 192.168.0.2 -p 456 -d RSS -k
   ```

Example 3, Adding an RS secondary server to a cluster

This example shows how to add an RS secondary server to the existing Informix® high-availability cluster. The following values are used for this example:

- Source server name: Amsterdam
- Source IP address: 192.168.0.1
- Source port: 123
- Target server name: Berlin
- Target IP address: 192.168.0.2
- Target port: 456

1. Create the onconfig and sqlhosts files and set the environment variables on the target computer.
2. On the target server, create all of the chunks that exist on the source server. You can use the **--createchunkfile** option (**-k**) to automatically create cooked chunks on the target server.Log-in as user **informix** and use the commands **touch**, **chown**, and **chmod** to create the chunks.
3. On the target server, run the **ifxclone** utility:

   ```
   ifxclone -T -L -S Amsterdam -I 192.168.0.1 -P 123 -t Berlin
            -i 192.168.0.2 -p 456 -s medium -d RSS -k
   ```

Prerequisites for cloning an ER server

Complete the following prerequisites before attempting to clone an ER server.

1. The source server (that is, the server that is being cloned) must have ER configured and active.
2. For configuration parameters that specify directory names, the directory names must exist on the target server. For example, if the CDR_LOG_STAGING_DIR configuration parameter is set to a directory name on the source server then the directory must also exist on the target server.
3. If ATS or RIS is enabled on the source server then the appropriate ATS or RIS directories must exist on the target server. See Enabling ATS and RIS File Generation and Creating ATS and RIS directories. If the directories do not exist then ATS/RIS spooling will fail.
4. If the source server has the CDR_SERIAL configuration parameter set then you must set the value for CDR_SERIAL to a different value on the server to be cloned. The value of CDR_SERIAL must be different on all replication servers. You can specify a unique value for the CDR_SERIAL configuration parameter by using the **--**

configParm (**-c**) parameter in the **ifxclone** command line.
5. The clock on the new ER clone must be appropriately synchronized. See Time synchronization.
6. The source server (that is, the server being cloned) must not have any stopped or suspended replicates, nor can it have any shadow replicates defined.

Avoid performing ER administrative tasks that change the set of replicates on which the target server participates while the **ifxclone** utility is running.

Example: Creating a clone of an ER server

Suppose you have five ER servers named S1, S2, S3, S4, and S5 currently configured as root servers in an ER domain. You would like to add a new server, S6, on a new computer named machine6, and you want it to have the same data as server S3.

1. Install and configure Informix database software on machine6. You can use the deployment utility to deploy a pre-configured database server instance.
2. Copy the sqlhosts file from server S3 to server S6 and modify it to add entries for the new server. For example, assuming the ER group name for the new server is g_S6 and the ID is 60, the sqlhosts file lines would look like the following.

```
g_S6    group     -           -         i=60
S6      onsoctcp  machine6    service6  g=g_S6
```

3. Add the two lines from the previous step in the sqlhosts files on all of the other five servers (S1 through S5).
4. Copy the onconfig file from server S3 to server S6 and change the DBSERVERNAME configuration parameter to S6. Do not modify any storage or chunk parameters except for path information.
5. On server S6 (machine6) provision chunk paths and other storage to the same sizes as server S3. Ensure that S6 has adequate memory and disk space resources. You can use the **--createchunkfile** option (**-k**) to automatically create cooked chunks on the target server.
6. Run the following command as user informix:

```
ifxclone -L -S S3 -I machine3 -P service3 -t S6 -i machine6 -p service6 -d ER -k
```

When prompted, enter the user name **informix** and then enter the password for user **informix**.

7. Monitor the server logs of servers S6 and S3. When the cloning process is complete you can check the status of servers by running the following command on servers S3 and S6:

```
cdr list server
```

You should see the new ER server g_S6 connected to all of the other five servers. In addition, ER node g_S6 will now participate in all replicates in which ER node g_S3 participates.

The onspaces utility

Use the **onspaces** utility to manage the storage spaces in your database.

- onspaces syntax
  Run **onspaces** utility commands to manage your storage spaces.
- onspaces -a: Add a chunk to a dbspace or blobspace
- onspaces -a: Add a chunk to an sbspace
- onspaces -c -b: Create a blobspace
- onspaces -c -d: Create a dbspace
  Use the **onspaces -c -d** command to create a dbspace or a temporary dbspace.
- onspaces -c -P: Create a plogspace
  Use the **onspaces -c -P** command to create a plogspace in which to store the physical log.
- onspaces -c -S: Create an sbspace
  Use the **onspaces -c -S** option to create a sbspace or a temporary sbspace.
- onspaces -c -x: Create an extspace
  Use the **onspaces -c -x** option to create an extspace.
- onspaces -ch: Change sbspace default specifications
  Use the **onspaces -ch** option to change the default specifications of a sbspace.
- onspaces -cl: Clean up stray smart large objects in sbspaces
  Use the **onspaces -cl** option to clean up stray smart large objects in sbspaces.
- onspaces -d: Drop a chunk in a dbspace, blobspace, or sbspace
  Use the **onspaces -d** option to drop a chunk in a dbspace, blobspace, or sbspace.
- onspaces -d: Drop a space
  Use the **onspaces -d** option to drop a dbspace, blobspace, plogspace, sbspace, or extspace.
- onspaces -f: Specify DATASKIP parameter
  Use the **onspaces -f** option to specify the value of the DATASKIP configuration parameter on a dbspace level or across all dbspaces.
- onspaces -m: Start mirroring
  Use the **onspaces -m** option to start mirroring for a dbspace, blobspace, or sbspace.
- onspaces -r: Stop mirroring
  Use the **onspaces -r** option to end mirroring for a dbspace, blobspace, or sbspace.
- onspaces -ren: Rename a dbspace, blobspace, sbspace, or extspace
  Use the **onspaces -ren** option to rename a dbspace, blobspace, sbspace, or extspace.
- onspaces -s: Change status of a mirrored chunk
  Use the **onspaces -s** option to change the status of a mirrored chunk in a dbspace, a non-primary chunk within a noncritical dbspace, a blobspace, or an sbspace.
- Avoid overwriting a chunk

                                        +- -r-------+
                                        +- -ren-----+
                                        +- -s-------+
                                        +- -V-------+
                                        '- -version-'
```

Notes:

1. See The -FILE option.

Element	Purpose	Key Considerations
-V	Shows the software version number and the serial number	See Obtaining utility version information
-version	Shows the build version, host, OS, build number, date, and the GLS version	See Obtaining utility version information

onspaces -a: Add a chunk to a dbspace or blobspace

Syntax:

```
>>-onspaces -a--+-dbspace---+--+- -p--pathname--------------+--->
                '-blobspace-'  |                            (1) |
                               '- -p--\--\--.--\--drive-----'

>-- -o--offset-- -s--size------------------------------------------>

>--+- -m--pathname offset--------------+----------------------><
   |                              (1) |
   '- -m--\--\--.--\--drive offset-----'
```

Notes:

1. Windows only

Use **onspaces -a** to add a chunk to a dbspace or blobspace.

Element	Purpose	Key considerations
-a	Indicates that a chunk is to be added	You can have up to 32766 chunks in an instance. You can put all those chunks in one storage space, or spread them among multiple storage spaces.
drive	Specifies the Windows drive to allocate as unbuffered disk space The format can be either **\\.\<*drive*>**, where ***drive*** is the drive letter assigned to a disk partition, or **\\.*PhysicalDrive*<*number*>**, where ***PhysicalDrive*** is a constant value and ***number*** is the physical drive number.	For more information, see Allocating raw disk space on Windows. Example: \\.\F: For path name syntax, see your operating-system documentation.
-m *pathname offset*	Specifies an optional path name and offset to the chunk that mirrors the new chunk Also see the entries for *pathname* and *offset* in this table.	For more information, see Adding a chunk to a dbspace or blobspace.
-o *offset*	After the **-a** option, *offset* indicates, in kilobytes, the offset into the disk partition or into the device to reach the initial chunk of the new blobspace or dbspace	Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 4 terabytes. For more information, see Allocating raw disk space on UNIX.

Element	Purpose	Key considerations
-p *pathname*	Indicates the disk partition or unbuffered device of the initial chunk of the blobspace or dbspace that you are adding The chunk must be an existing unbuffered device or buffered file.	The chunk path name can be up to 256 bytes. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. UNIX example (unbuffered device): /dev/rdsk/c0t3d0s4 UNIX example (buffered device): /ix/ids9.2/db1chunk Windows example: c:\Ifmxdata\ol_icecream\mychunk1.dat For path name syntax, see your operating-system documentation.
-s *size*	Indicates, in kilobytes, the size of the new blobspace or dbspace chunk	Unsigned integer. The size must be equal to or greater than 1000 kilobytes and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 4 terabytes.
blobspace	Names the blobspace to which you are adding a chunk	See Adding a chunk to a dbspace or blobspace. Syntax must conform to the Identifier.
dbspace	Names the dbspace to which you are adding a chunk	See Adding a chunk to a dbspace or blobspace. Syntax must conform to the Identifier.

This command has an equivalent SQL administration API function.

Related reference:
Avoid overwriting a chunk
add chunk argument: Add a new chunk (SQL administration API)
create chunk argument: Create a chunk (SQL administration API)

onspaces -a: Add a chunk to an sbspace

```
Syntax:

>>-onspaces -a--sbspace-- -p--pathname-- -o--offset------------>

>-- -s--size--+----------------------+--+--------------+-------->
              '- -m--pathname offset-'  '- -Ms--mdsize-'

>--+----------------+--+-----+---------------------------------><
   '- -Mo--mdoffset-'  '- -U-'
```

Use **onspaces -a** to add a chunk to an sbspace.

Element	Purpose	Key considerations
-a	Indicates that a chunk is to be added	You can have up to 32766 chunks in an instance. You can put all those chunks in one storage space, or spread them among multiple storage spaces.
-m *pathname offset*	Specifies an optional path name and offset to the chunk that mirrors the new chunk Also see the entries for ***pathname*** and ***offset*** in this table.	For background information, see adding a chunk to an sbspace, in the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*.
-Mo *mdoffset*	Indicates, in kilobytes, the offset into the disk partition or into the device where metadata should be stored	Value can be an integer between 0 and the chunk size. You cannot specify an offset that causes the end of the metadata space to be past the end of the chunk. For background information, see sizing sbspace metadata, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-Ms *mdsize*	Specifies the size, in kilobytes, of the metadata area allocated in the initial chunk. The remainder is user-data space	Value can be an integer between 0 and the chunk size. For background information, see sizing sbspace metadata, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-o *offset*	After the **-a** option, *offset* indicates, in kilobytes, the offset into the disk partition or into the unbuffered device to reach the initial chunk of the new blobspace or dbspace.	Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 2 or 4 terabytes, depending on the platform. For more information, see allocating raw disk space on UNIX, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-p *pathname*	Indicates the disk partition or unbuffered device of the initial chunk of the sbspace that you are creating The chunk must be an existing unbuffered device or buffered file.	The chunk path name can be up to 256 bytes. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. For path name syntax, see your operating-system documentation.
-U	Specifies that the entire chunk should be used to store user data	The **-M** and **-U** options are mutually exclusive. For background information, see adding a chunk to an sbspace, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-s *size*	Indicates, in kilobytes, the size of the new sbspace chunk	Unsigned integer. The size must be equal to or greater than 1000 kilobytes and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 4 terabytes

Element	Purpose	Key considerations
sbspace	Names the sbspace to which you are adding a chunk	See adding a chunk to an sbspace in the chapter on managing disk space in the *IBM Informix Administrator's Guide*. Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*.

This command has an equivalent SQL administration API function.

Related reference:
Avoid overwriting a chunk
add chunk argument: Add a new chunk (SQL administration API)
create chunk argument: Create a chunk (SQL administration API)

onspaces -c -b: Create a blobspace

```
Syntax:

>>-onspaces -c---- -b--blobspace-- -g--pageunit----------------->

>--+- -p--pathname--------------+-- -o--offset-- -s--size------->
   |                      (1) |
   '- -p--\--\--.--\--drive-----'

>--+-------------------------------------+--+-----+-------------><
   +- -m--pathname offset--------------+  '- -u-'
   |                                   (1) |
   '- -m--\--\--.--\--drive offset-----'
```

Notes:

1. Windows Only

Use **onspaces -c -b** to create a blobspace.

Element	Purpose	Key considerations
-b *blobspace*	Names the blobspace to be created	The blobspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the $ character. For more information, see creating a blobspace, in the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*. The syntax must conform to the Identifier segment. For more information, see the *IBM Informix Guide to SQL: Syntax*.
-c	Creates a dbspace, blobspace, sbspace, or extspace You can create up to 2047 storage spaces of any type.	After you create a storage space, you must back up both this storage space and the root dbspace. If you create a storage space with the same name as a deleted storage space, perform another level-0 backup to ensure that future restores do not confuse the new storage space with the old one. For more information, see creating a dbspace, blobspace, or extspace, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
drive	Specifies the Windows drive to allocate as unbuffered disk space The format can be either \\.\<*drive*>, where *drive* is the drive letter assigned to a disk partition, or \\.*PhysicalDrive*<*number*>, where *PhysicalDrive* is a constant value and *number* is the physical drive number.	For information on allocating unbuffered disk space, see allocating unbuffered disk space on Windows in the chapter on managing disk space in the *IBM Informix Administrator's Guide*. Examples: `\\.\F:` `\\.\PhysicalDrive2` For path name syntax, see your operating-system documentation.
-g *pageunit*	Specifies the blobspace blobpage size in terms of *page_unit*, the number of the base page size of the instance (either 2K or 4K)	Unsigned integer. Value must be greater than 0. The maximum number of pages that a blobspace can contain is 2147483647. Therefore, the size of the blobspace is limited to the blobpage size x 2147483647. This includes blobpages in all chunks that make up the blobspace. For more information, see blobpage size considerations, in the chapter on I/O Activity in the *IBM Informix Performance Guide*.
-m *pathname offset*	Specifies an optional path name and offset to the chunk that mirrors the initial chunk of the new blobspace or dbspace Also see the entries for **-p** *pathname* and **-o** *offset* in this table.	For more information, see creating a dbspace or a blobspace in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-o *offset*	Indicates, in kilobytes, the offset into the disk partition or into the device to reach the initial chunk of the new blobspace, dbspace, or sbspace	Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 2 or 4 terabytes, depending on the platform. For more information, see allocating raw disk space, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.

Element	Purpose	Key considerations
-p *pathname*	Indicates the disk partition or device of the initial chunk of the blobspace or dbspace that you are creating	The chunk must be an existing unbuffered device or buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. UNIX example (unbuffered device): /dev/rdsk/c0t3d0s4 UNIX example (buffered device): /ix/ids9.2/db1chunk Windows example:c:\Ifmxdata\ol_icecream\mychunk1.dat For path name syntax, see your operating-system documentation.
-s *size*	Indicates, in kilobytes, the size of the initial chunk of the new blobspace or dbspace	Unsigned integer. The size must be equal to or greater than 1000 kilobytes and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 2 or 4 terabytes, depending on the platform.
-u	Specifies to create an unencrypted space	Use this option to create an unencrypted storage space when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This command has an equivalent SQL administration API function.

Related reference:
Avoid overwriting a chunk
create blobspace argument: Create a blobspace (SQL administration API)
DISK_ENCRYPTION configuration parameter

onspaces -c -d: Create a dbspace

Use the **onspaces -c -d** command to create a dbspace or a temporary dbspace.

Syntax

```
>>-onspaces -c---- -d--dbspace----+- -p--pathname----------+---->
                                  '- -p--\--\--.--\--drive-'

>-- -o--offset-- -s--size----------------------------------------->

>--+-------------------------------------+---------------------->
   +- -ef--extentsize-- -en--extentsize-+
   '- -t--------------------------------'

>--+-------------------------------------+--+---------------+----->
   +- -m--pathname offset--------------+  '- -k--pagesize-'
   |                                   (1) |
   '- -m--\--\--.--\--drive offset-----'

>--+-----+-------------------------------------------------------><
   '- -u-'
```

Notes:

1. Windows Only

Element	Purpose	Key considerations
-c	Creates a dbspace You can create up to 2047 storage spaces of any type.	After you create a storage space, you must back up both this storage space and the root dbspace. If you create a storage space with the same name as a deleted storage space, perform another level-0 backup to ensure that future restores do not confuse the new storage space with the old one. For more information, see Manage dbspaces.
drive	Specifies the Windows drive to allocate as unbuffered disk space The format can be either \\.*drive*, where *drive* is the drive letter that is assigned to a disk partition, or \\.*PhysicalDrivenumber*, where *PhysicalDrive* is a constant value and *number* is the physical drive number.	For information on allocating unbuffered disk space, see Allocating raw disk space on Windows. Examples: `\\.\F:` `\\.\PhysicalDrive2` For path name syntax, see your operating-system documentation.
-d *dbspace*	Names the dbspace to be created	The dbspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the $ character. For more information, see Manage dbspaces. The syntax must conform to the Identifier segment. For more information, see Identifier.

Element	Purpose	Key considerations
-ef *extentsize*	Indicates, in KB, the size of the first extent for the tblspace **tblspace**	The minimum, and default, size of the first extent for the tblspace **tblspace** of a non-root dbspace is equivalent to 50 dbspace pages, which are specified in KB. For example: 100 KB for a 2 KB page size dbspace, 200 KB for a 4 KB page size dbspace, 400 KB for an 8 KB page size dbspace. The maximum size of a tblspace **tblspace** extent is 1048575 pages minus the space that is needed for any system objects. On a 2 KB page size system, the maximum size is approximately 2 GB. For more information, see Specifying the first and next extent sizes for the tblspace tblspace.
-en *extentsize*	Indicates, in KB, the size of the next extents in the tblspace **tblspace**	The minimum size of the next extents for the tblspace **tblspace** of a non-root dbspace is equivalent to 4 dbspace pages, which are specified in KB. For example: 8 KB for a 2 KB page size dbspace, 16 KB for a 4 KB page size dbspace, 32 KB for an 8 KB page size dbspace. The default size for a next extent is 50 dbspace pages. The maximum size of a tblspace **tblspace** extent is 1048572 pages. On a 2 KB page size system, the maximum size is approximately 2 GB. If there is not enough space for a next extent in the primary chunk, the extent is allocated from another chunk. If the specified space is not available, the closest available space is allocated. For more information, see Specifying the first and next extent sizes for the tblspace tblspace.
-k *pagesize*	Indicates in KB, the non-default page size for the new dbspace. For systems with sufficient storage, performance advantages of a larger page size can include the following: • Reduced depth of B-tree indexes, even for smaller index keys • You can group on the same page long rows that currently span multiple pages of the default page size • Checkpoint time is typically reduced with larger pages • You can define a different page size for temporary tables so that they have a separate buffer pool.	The page size must be between 2 KB and 16 KB and must be a multiple of the default page size. For example, if the default page size is 2 KB, then *pagesize* can be 2, 4, 6, 8, 10, 12, 14, or 16. If the default page size is 4 KB (Windows), then *pagesize* can be 4, 8, 12, or 16. For more information, see Creating a dbspace with a non-default page size.
-m *pathname offset*	Specifies an optional path name and offset to the chunk that mirrors the initial chunk of the new dbspace Also see the entries for **-p** *pathname* and **-o** *offset* in this table.	For more information, see Manage dbspaces.
-o *offset*	Indicates, in KB, the offset into the disk partition or into the device to reach the initial chunk of the new dbspace	Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The offset must be a multiple of the page size. The maximum offset is 2 or 4 TB, depending on the platform. For more information, see Allocating raw disk space on Windows.
-p *pathname*	Indicates the disk partition or device of the initial chunk of the dbspace that you are creating	The chunk must be an existing unbuffered device or buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. UNIX example (unbuffered device): /dev/rdsk/c0t3d0s4 UNIX example (buffered device): /ix/ids9.2/db1chunk Windows example:c:\Ifmxdata\ol_icecream\mychunk1.dat For path name syntax, see your operating-system documentation.
-s *size*	Indicates, in KB, the size of the initial chunk of the new dbspace	Unsigned integer. The size must be equal to or greater than 1000 KB and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 2 or 4 TB, depending on the platform.
-t	Creates a temporary dbspace for storage of temporary tables	You cannot mirror a temporary dbspace. You cannot specify the first and next extent sizes for the tblspace **tblspace** of a temporary dbspace. For more information, see Temporary dbspaces.
-u	Specifies to create an unencrypted space	Use this option to create an unencrypted storage space when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

The maximum size of a dbspace is equal to the maximum number of chunks multiplied by the maximum size of a chunk. (The maximum number of chunks is 32766 per instance. The maximum size of a chunk is equal to 2147483647 pages multiplied by the page size.)

This command has an equivalent SQL administration API function.

You cannot change the page size of a dbspace after you create it.

You cannot store logical or physical logs in a dbspace that is not the default platform page size.

If a dbspace is created when a buffer pool with that page size does not exist, Informix® creates a buffer pool using the values of the fields of the **default** line of the BUFFERPOOL parameter.

Temporary dbspaces

When you create a temporary dbspace with **onspaces**, the database server uses the newly created temporary dbspace, after you add the name of the new temporary dbspace to your list of temporary dbspaces in the DBSPACETEMP configuration parameter, the DBSPACETEMP environment variable, or both and restart the server.

You cannot specify the first and next extent of a temporary dbspace. The extent size for temporary dbspaces is 100 KB for a 2 KB page system or 200 KB for a 4 KB page system.

You can specify the first and next space of the tblspace **tblspace** in the root dbspace if you do not want the database server to automatically manage the size. To specify the first and next extent sizes of a root tblspace **tblspace**, use the TBLTBLFIRST and TBLTBLNEXT configuration parameters before you create the root dbspace the first time that you start the database server.

Specifying the first and next extent sizes for the tblspace tblspace

onspaces -c -P: Create a plogspace

Use the **onspaces -c -P** command to create a plogspace in which to store the physical log.

Syntax

```
>>-onspaces -c---- -P--plogspace--------------------------------->

>--+- -p--pathname----------+-- -o--offset-- -s--size----------->
   '- -p--\--\--.--\--drive-'

>--+-------------------------------------+--+-----+-------------><
   +- -m--pathname --offset------------+  '- -u-'
   |                                   (1) |
   '- -m--\--\--.--\--drive offset-----'
```

Notes:

1. Windows Only

Element	Purpose	Key considerations
-c	Creates a plogspace.	An instance can have only one plogspace. If a plogspace exists, creating a new one moves the physical log to the new space and drops the old plogspace.
-m *pathname offset*	Specifies an optional path name and offset to the chunk that mirrors the chunk of the new plogspace. See **-p** *pathname* and **-o** *offset* in this table.	If you mirror the plogspace, the plogspace chunk cannot be extendable.
-m \\.*drive*	Specifies the Windows drive for the chunk that mirrors the chunk of the new plogspace. The *drive* is the drive letter that is assigned to a disk partition or a constant value and the physical drive number.	Examples: **\\.\F:** **\\.\PhysicalDrive2** For drive name syntax, see your operating-system documentation.
-o *offset*	Indicates, in KB, the offset into the disk partition or into the device to reach the chunk of the new plogspace.	Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The offset must be a multiple of the page size. The maximum offset is 2 or 4 TB, depending on the platform.
-P *plogspace*	Names the plogspace to be created.	The plogspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the $ character. The syntax must conform to the Identifier segment. For more information, see Identifier.

Element	Purpose	Key considerations
-p *pathname*	Indicates the disk partition or device of the chunk of the plogspace that you are creating.	The chunk must be an existing unbuffered device or buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. UNIX example (unbuffered device): /dev/rdsk/c0t3d0s4 UNIX example (buffered device): /ix/ifmx/db1chunk Windows example: c:\Ifmxdata\ol_icecream\mychunk1.dat
-p \\.*drive*	Specifies the Windows drive to allocate as unbuffered disk space for the plogspace. The *drive* is the drive letter that is assigned to a disk partition or a constant value and the physical drive number.	Examples: `\\.\F:` `\\.\PhysicalDrive2` For drive name syntax, see your operating-system documentation.
-s *size*	Indicates, in KB, the size of the chunk of the new plogspace.	Unsigned integer. The size must be equal to or greater than 1000 KB and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 2 or 4 TB, depending on the platform.
-u	Specifies to create an unencrypted space	Use this option to create an unencrypted storage space when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

The physical log must be stored on a single chunk. By default the chunk for the plogspace is extendable and the database server expands the plogspace as needed to improve performance.

Examples

The following example creates a plogspace that is called **plogdbs** that has a size of 40000 KB and an offset of 0:

```
onspaces -c -P plogdbs -p /dev/chk1 -o 0 -s 40000
```

The following example creates a mirrored plogspace that is called **pdbs1** that has a size of 60000 KB and an offset of 500 KB:

```
onspaces -c -P pdbs1 -p /dev/pchk1 -o 500 -s 60000 -m /dev/mchk1 0
```

Related reference:
create plogspace: Create a plogspace (SQL administration API)

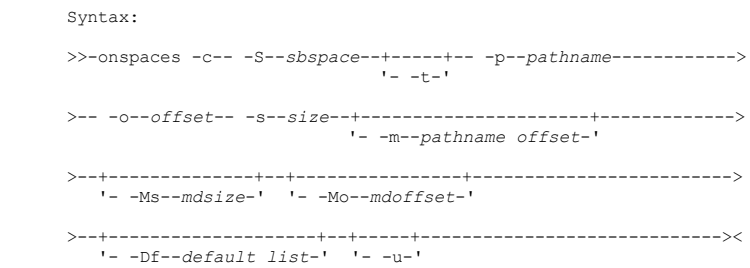
Related information:
Plogspace
Manage the plogspace

onspaces -c -S: Create an sbspace

Use the **onspaces -c -S** option to create a sbspace or a temporary sbspace.

Syntax:



Element	Purpose	Key Considerations
-S*sbspace*	Names the sbspace to be created	The sbspace name must be unique and must not exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the $ character. Syntax must conform to the Identifier segment; see the *IBM® Informix® Guide to SQL: Syntax*.
-c	Creates an sbspace You can create up to 32767 storage spaces of any type.	None.

Element	Purpose	Key Considerations
-Df *default list*	Lists default specifications for smart large objects stored in the sbspace	Restrictions: Tags are separated by commas. If a tag is not present, system defaults take precedence. The list must be enclosed in double quotation marks (“) on the command line. References: For a list of tags and their parameters, see Table 1.
-m *pathname offset*	Specifies an optional pathname and offset to the chunk that mirrors the initial chunk of the new sbspace Also see the entries for **-p** *pathname* and **-o** *offset* in this table.	For more information, see sbspaces in the chapter on data storage, and creating an sbspace, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-Mo *mdoffset*	Indicates, in kilobytes, the offset into the disk partition or into the device where metadata will be stored.	Restrictions: Value can be an integer between 0 and the chunk size. You cannot specify an offset that causes the end of the metadata space to be past the end of the chunk. References: For more information, see sizing sbspace metadata, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-Ms *mdsize*	Specifies the size, in kilobytes, of the metadata area allocated in the initial chunk The remainder is user-data space.	Restrictions: Value can be an integer between 0 and the chunk size.
-o *offset*	Indicates, in kilobytes, the offset into the disk partition or into the device to reach the initial chunk of the sbspace	Restrictions: Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 4 terabytes for systems with a two-kilobyte page size and 8 terabytes for systems with a four-kilobyte page size. References: For more information, see allocating raw disk space on UNIX, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-p *pathname*	Indicates the disk partition or unbuffered device of the initial chunk of the sbspace	The chunk must be an existing unbuffered device or buffered file. When you specify a pathname, you can use either a full pathname or a relative pathname. However, if you use a relative pathname, it must be relative to the directory that was the current directory when you initialized the database server. References: For pathname syntax, see your operating-system documentation.
-s *size*	Indicates, in kilobytes, the size of the initial chunk of the new sbspace	Restrictions: Unsigned integer. The size must be equal to or greater than 1000 kilobytes and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 2 or 4 terabytes, depending on the platform.
-t	Creates a temporary sbspace for storage of temporary smart large objects. You can specify the size and offset of the metadata area	Restrictions: You cannot mirror a temporary sbspace. You can specify any **-Df** option, except the LOGGING=ON option, which has no effect. **References**: For more information, see Creating a Temporary Sbspace with the -t Option.
-u	Specifies to create an unencrypted space	Use this option to create an unencrypted storage space when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

- Creating a Temporary Sbspace with the -t Option
- Creating an Sbspace with the -Df option
- Changing the -Df Settings
- Using the onspaces -g option

SBSPACETEMP configuration parameter
SYSSBSPACENAME configuration parameter
Avoid overwriting a chunk
create sbspace argument: Create an sbspace (SQL administration API)
create tempsbspace argument: Create a temporary sbspace (SQL administration API)
create sbspace with log argument: Create an sbspace with transaction logging (SQL administration API)
DISK_ENCRYPTION configuration parameter

Creating a Temporary Sbspace with the -t Option

This example creates a temporary sbspace of 1000 kilobytes:

```
onspaces -c -S tempsbsp -t -p ./tempsbsp -o 0 -s 1000
```

You can optionally specify the name of the temporary sbspace in the SBSPACETEMP configuration parameter. Restart the database server so that it can use the temporary sbspace.

Creating an Sbspace with the -Df option

When you create an sbspace with the optional **-Df** option, you can specify several default specifications that affect the behavior of the smart large objects stored in the sbspace. The default specifications must be expressed as a list separated by commas. The list need not contain all of the tags. The list of tags must be enclosed in double quotation marks (“). The table in Table 1 describes the tags and their default values.

The four levels of inheritance for sbspace characteristics are system, sbspace, column, and smart large objects. For more information, see smart large objects in the chapter on where data is stored in the *IBM® Informix Administrator's Guide*.

Table 1. -Df Default Specifications

Tag	Values	Default	Description
ACCESSTIME	ON or OFF	OFF	When set to ON, the database server tracks the time of access to all smart large objects stored in the sbspace. For information about altering storage characteristics of smart large objects, see the *IBM Informix DataBlade API Programmer's Guide*.
AVG_LO_SIZE	Windows: 4 to 2**31 UNIX: 2 to 2**31	8	Specifies the average size, in kilobytes, of the smart large object stored in the sbspace The database server uses this value to calculate the size of the metadata area. Do not specify AVG_LO_SIZE and **-Ms** together. You can specify AVG_LO_SIZE and the metadata offset (**-Mo**) together. If the size of the smart large object exceeds 2**31, specify 2**31. If the size of the smart large object is less than 2 on UNIX or less than 4 in Windows, specify 2 or 4. Error 131 is returned if you run out of space in the metadata and reserved areas in the sbspace. To allocate additional chunks to the sbspace that consist of metadata area only, use the **-Ms** option instead. For more information, see creating smart large objects, in the chapter on managing data on disk in the *IBM Informix Administrator's Guide*.
BUFFERING	ON or OFF	ON	Specifies the buffering mode of smart large objects stored in the sbspace If set to ON, the database server uses the buffer pool in the resident portion of shared memory for smart-large-object I/O operations. If set to OFF, the database server uses light I/O buffers in the virtual portion of shared memory (lightweight I/O operations). BUFFERING = OFF is incompatible with LOCK_MODE = RANGE and creates a conflict For more information, see lightweight I/O, in the chapter on configuration effects on memory in the *IBM Informix Performance Guide*.
LOCK_MODE	RANGE or BLOB	BLOB	Specifies the locking mode of smart large objects stored in the sbspace If set to RANGE, only a range of bytes in the smart large object is locked. If set to BLOB, the entire smart large object is locked. LOCK_MODE = RANGE is incompatible with BUFFERING = OFF and creates a conflict. For more information, see smart large objects, in the chapter on locking in the *IBM Informix Performance Guide*.
LOGGING	ON or OFF	OFF	Specifies the logging status of smart large objects stored in the sbspace If set to ON, the database server logs changes to the user data area of the sbspace. When you turn on logging for an sbspace, take a level-0 backup of the sbspace. When you turn off logging, the following message displays: You are turning off smart large object logging. For more information, see smart large objects, in the chapters on data storage and logging in the *IBM Informix Administrator's Guide*. For information about **onspaces -ch** messages, see Messages in the database server log.
EXTENT_SIZE	4 to 2**31	None	Specifies the size, in kilobytes, of the first allocation of disk space for smart large objects stored in the sbspace when you create the table Let the system select the EXTENT_SIZE value. To reduce the number of extents in a smart large object, use **mi_lo_specset_estbytes** (DataBlade API) or **ifx_lo_specset_estbytes** (Informix® ESQL/C) to hint to the system the total size of the smart large object. The system attempts to allocate a single extent for the smart large object. For more information, see smart large objects, in the chapter on where data is stored in the *IBM Informix Administrator's Guide*. For information about altering storage characteristics of smart large objects, see the *IBM Informix DataBlade API Programmer's Guide* or the *IBM Informix ESQL/C Programmer's Manual*.
MIN_EXT_SIZE	2 to 2**31	Windows: 4UNIX: 2	Specifies the minimum amount of space, in kilobytes, to allocate for each smart large object The following message displays: Changing the sbspace minimum extent size: old value *value1* new value *value2*. For information about tuning this value, see smart large objects, in the chapter on configuration effects on I/O utilization in the *IBM Informix Performance Guide*. For information about **onspaces -ch** messages, see Messages in the database server log.

Tag	Values	Default	Description
NEXT_SIZE	4 to 2**31	None	Specifies the extent size, in kilobytes, of the next allocation of disk space for smart large objects when the initial extent in the sbspace becomes full. Let the system select the NEXT_SIZE value. To reduce the number of extents in a smart large object, use **mi_lo_specset_estbytes** or **ifx_lo_specset_estbytes** to hint to the system the total size of the smart large object. The system attempts to allocate a single extent for the smart large object. For more information, see smart large objects, in the chapter on where data is stored in the *IBM Informix Administrator's Guide*. For information about obtaining the size of smart large objects, see the *IBM Informix DataBlade API Programmer's Guide* or the *IBM Informix ESQL/C Programmer's Manual*.

This example creates a 20-megabyte mirrored sbspace, **eg_sbsp,** with the following specifications:

- An offset of 500 kilobytes for the primary and mirror chunks
- An offset of 200 kilobytes for the metadata area
- An average expected smart-large-object size of 32 kilobytes
- Log changes to the smart large objects in the user-data area of the sbspace

UNIX Only:

```
% onspaces -c -S eg_sbsp -p /dev/raw_dev1 -o 500 -s 20000
   -m /dev/raw_dev2 500 -Mo 200 -Df "AVG_LO_SIZE=32,LOGGING=ON"
```

Changing the -Df Settings

As the database server administrator, you can override or change the **-Df** default settings in one of the following ways:

- To change the default settings for an sbspace, use the **onspaces -ch** option. For more information, refer to onspaces -ch: Change sbspace default specifications.
- To override the following **-Df** default settings for a specific table, use the SQL statements CREATE TABLE or ALTER TABLE:
  - LOGGING
  - ACCESSTIME
  - EXTENT_SIZE
  - NEXT_SIZE

  For more information on the ALTER TABLE and CREATE TABLE statements, see the *IBM® Informix Guide to SQL: Syntax*.

The programmer can override these **-Df** default settings with DataBlade API and Informix® ESQL/C functions. For information about altering storage characteristics of smart large objects, see the *IBM Informix DataBlade API Programmer's Guide* and the *IBM Informix ESQL/C Programmer's Manual*.

Using the onspaces -g option

The **onspaces -g** option is not used for sbspaces. The database server uses a different method to determine the number of pages to transfer in an I/O operation for sbspaces than for blobspaces. The database server can automatically determine the block size to transfer in an I/O operation for smart large objects. For more information, see sbspace extent sizes in the chapter on I/O activity in your *IBM® Informix® Performance Guide*.

This command has an equivalent SQL administration API function.

onspaces -c -x: Create an extspace

Use the **onspaces -c -x** option to create an extspace.

Syntax:

```
>>-onspaces -c-- -x--extspace-- -l--location-- -o--offset------->

>-- -s--size-------------------------------------------------><
```

Element	Purpose	Key Considerations
-c	Creates a dbspace, blobspace, sbspace, or extspace You can create up to 2047 storage spaces of any type.	After you create a storage space, you must back up both this storage space and the root dbspace. If you create a storage space with the same name as a deleted storage space, perform another level-0 backup to ensure that future restores do not confuse the new storage space with the old one. For more information, see creating a dbspace, blobspace, or extspace, in the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*.

Element	Purpose	Key Considerations
-l *location*	Specifies the location of the extspace The access method determines the format of this string.	**Restrictions**: String. Value must not be longer than 255 bytes. For more information, see creating an extspace, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-o *offset*	Indicates, in kilobytes, the offset into the disk partition or into the device to reach the initial chunk of the new blobspace, dbspace, or sbspace	**Restrictions**: Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 2 or 4 terabytes, depending on the platform. For more information, see allocating raw disk space, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-s*size*	Indicates, in kilobytes, the size of the initial chunk of the new blobspace or dbspace	**Restrictions**: Unsigned integer. The size must be equal to or greater than 1000 kilobytes and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 2 or 4 terabytes, depending on the platform.
-x *extspace*	Names the extspace to be created	**Restrictions**: Extspace names can be up to 128 bytes. They must be unique, begin with a letter or underscore, and contain only letters, digits, underscores, or **$** characters. For more information, see extspaces, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.

Related reference:
DISK_ENCRYPTION configuration parameter

onspaces -ch: Change sbspace default specifications

Use the **onspaces -ch** option to change the default specifications of a sbspace.

Syntax:

```
>>-onspaces -ch--sbspace-- -Df--default list------------------><
```

Element	Purpose	Key Considerations
-ch	Indicates that one or more sbspace default specifications are to be changed	None.
sbspace	Names the sbspace for which to change the default specifications	Syntax must conform to the Identifier segment; see the *IBM® Informix® Guide to SQL: Syntax*. For background information, see changing default specifications of an sbspace with **onspaces** in the *IBM Informix Performance Guide*.
-Df *default list*	Lists new default specifications for smart large objects stored in the sbspace	Tags are separated by commas. If a tag is not present, system defaults take precedence. The list must be enclosed in double quotation marks (“) on the command line. For a list of tags and their parameters, see Table 1.

You can change any of the **-Df** tags with the **onspaces -ch** option. The database server applies the change to each smart large object that was created prior to changing the default specification.

For example, to turn off logging for the sbspace that you created in Creating an Sbspace with the -Df option, use the following command:

```
onspaces -ch eg_sbsp -Df "LOGGING=OFF"
```

Note: After you turn on logging for an sbspace, take a level-0 backup of the sbspace to create a point from which to recover.
Related reference:
set sbspace accesstime argument: Control access time tracking (SQL administration API)
set sbspace avg_lo_size argument: Set the average size of smart large objects (SQL administration API)
set sbspace logging argument: Change the logging of an sbspace (SQL administration API)

onspaces -cl: Clean up stray smart large objects in sbspaces

Use the **onspaces -cl** option to clean up stray smart large objects in sbspaces.

Syntax:

```
>>-onspaces -cl--sbspace----------------------------------------><
```

Element	Purpose	Key Considerations
-cl	Cleans up stray smart large objects in an sbspace	To find any stray smart large objects, use the **oncheck -pS** command when no users are connected to the database server. The smart large objects with a reference count of 0 are stray objects.

Element	Purpose	Key Considerations
sbspace	Names the sbspace to be cleaned up	Syntax must conform to the Identifier segment; see the *IBM® Informix® Guide to SQL: Syntax*.

During normal operation, no unreferenced (stray) smart large objects should exist. When you delete a smart large object, the space is released. If the database server fails or runs out of system memory while you are deleting a smart large object, the smart large object might remain as a stray object.

The following is an example of the **onspaces -cl** command:

```
onspaces -cl myspace
```

The best way to find the reference count for a smart large object is to call the **mi_lo_stat** or **ifx_lo_stat** functions from a C program. Although the **mi_lo_increfcount** and **mi_lo_decrefcount** functions return the reference count, they increment or decrement the reference count. For more information on these functions, see the *IBM Informix DataBlade API Function Reference*.

This command has an equivalent SQL administration API function.

Related reference:
clean sbspace argument: Release unreferenced smart large objects (SQL administration API)

onspaces -d: Drop a chunk in a dbspace, blobspace, or sbspace

Use the **onspaces -d** option to drop a chunk in a dbspace, blobspace, or sbspace.

Syntax:

```
>>-onspaces -d--+-dbspace----------+-- -p--pathname------------>
                +-blobspace--------+
                '-+-----+--sbspace-'
                  '- -f-'

>-- -o--offset--+-----+---------------------------------------><
                '- -y-'
```

This command has an equivalent SQL administration API function.

Element	Purpose	Key considerations
-d	Drops a chunk	You can drop a chunk from a dbspace, temporary dbspace, or sbspace when the database server is online or quiescent. For more information, see the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*. You can drop a chunk from a blobspace only when the database server is in quiescent mode.
-f	Drops an sbspace chunk that contains user data but no metadata If the chunk contains metadata for the sbspace, you must drop the entire sbspace.	Use the **-f** option with sbspaces only. If you omit the **-f** option, you cannot drop an sbspace that contains data. For more information, see dropping a chunk from an sbspace with **onspaces**, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-o *offset*	Indicates, in kilobytes, the offset into the disk partition or into the unbuffered device to reach the initial chunk of the dbspace, blobspace, or sbspace that you are dropping	**Restrictions**: Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 4 terabytes. For more information, see allocating raw disk space on UNIX, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
-p *pathname*	Indicates the disk partition or unbuffered device of the initial chunk of the dbspace, blobspace, or sbspace that you are dropping	The chunk must be an existing unbuffered device or buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. For path name syntax, see your operating-system documentation.
-y	Causes the database server to automatically respond yes to all prompts	None.
blobspace	Names the blobspace from which the chunk is dropped	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see dropping a chunk from a blobspace, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
dbspace	Names the dbspace from which the chunk is dropped	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see dropping a chunk from a dbspace with **onspaces**, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
sbspace	Names the sbspace from which the chunk is dropped	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For background information, see dropping a chunk from a dbspace with **onspaces**, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.

Important: You must specify a path name to indicate to the database server that you are dropping a chunk.
Related reference:
drop chunk argument: Drop a chunk (SQL administration API)
drop plogspace: Drop the plogspace (SQL administration API)

onspaces -d: Drop a space

Use the **onspaces -d** option to drop a dbspace, blobspace, plogspace, sbspace, or extspace.

Syntax:

```
>>-onspaces -d--+-dbspace----------+--+-----+-----------------><
               +-blobspace--------+  '- -y-'
               +-plogspace--------+
               +-+-----+--sbspace-+
               | '- -f-'          |
               '-extspace---------'
```

Element	Purpose	Key considerations
-d	Indicates that a storage space is to be dropped	You can drop a dbspace, blobspace, plogspace, sbspace, or extspace while the database server is online or in quiescent mode. After you drop a storage space, you must back it up to ensure that the **sysutils** database and the reserved pages are up-to-date. Run **oncheck -pe** to verify that no table is storing data in the dbspace, blobspace, or sbspace.
-y	Causes the database server to automatically respond yes to all prompts	None.
-f	Drops an sbspace that contains user data and metadata	You must use the **-f** (force) option to drop an sbspace that contains data. Restriction: Use the **-f** option with sbspaces only. Warning: If you use the **-f** option, the tables in the database server might have dead pointers to the smart large objects that were deleted with this option.
blobspace	Names the blobspace to be dropped	Before you drop a blobspace, drop all tables that include a TEXT or BYTE column that references the blobspace.
dbspace	Names the dbspace to be dropped	Before you drop a dbspace, drop all databases and tables that you previously created in the dbspace.
extspace	Names the extspace to be dropped	You cannot drop an extspace if it is associated with an existing table or index.
plogspace	Names the plogspace to be dropped	The plogspace must be empty to be dropped.
sbspace	Names the sbspace to be dropped	Before you drop an sbspace, drop all tables that include a BLOB or CLOB column that references the sbspace.

Important: Do not specify a path name when you drop these storage spaces.
This command has an equivalent SQL administration API function.

Related reference:
drop blobspace argument: Drop a blobspace (SQL administration API)
drop dbspace argument: Drop a dbspace (SQL administration API)
drop sbspace argument: Drop an sbspace (SQL administration API)
drop tempdbspace argument: Drop a temporary dbspace (SQL administration API)

onspaces -f: Specify DATASKIP parameter

Use the **onspaces -f** option to specify the value of the DATASKIP configuration parameter on a dbspace level or across all dbspaces.

Syntax:

```
>>-onspaces -f--+-OFF-+--+--------------+--+-----+-------------><
               '-ON--'  '-dbspace-list-'  '- -y-'
```

This command has an equivalent SQL administration API function.

Element	Purpose	Key considerations
-f	Indicates to the database server that you want to change the DATASKIP default for specified dbspaces or all dbspaces	All changes in the DATASKIP status are recorded in the message log.
-y	Causes the database server to automatically respond yes to all prompts	None.
dbspace-list	Specifies the name of one or more dbspaces for which DATASKIP will be turned ON or OFF	Syntax must conform to the Identifier segment; see the *IBM® Informix® Guide to SQL: Syntax*. For more information, see DATASKIP Configuration Parameter and the *IBM Informix Performance Guide*.
OFF	Turns off DATASKIP	If you use OFF without *dbspace-list*, DATASKIP is turned off for all fragments. If you use OFF with *dbspace-list*, only the specified fragments are set with DATASKIP off.

Element	Purpose	Key considerations
ON	Turns on DATASKIP	If you use ON without *dbspace-list*, DATASKIP is turned on for all fragments. If you use ON with dbspace-list, only the specified fragments are set with DATASKIP on.

Related reference:
set dataskip argument: Start or stop skipping a dbspace (SQL administration API)
DATASKIP Configuration Parameter

onspaces -m: Start mirroring

Use the **onspaces -m** option to start mirroring for a dbspace, blobspace, or sbspace.

Syntax:

```
>>-onspaces -m--+-dbspace---+----------------------------------->
                +-blobspace-+
                '-sbspace---'

   .-,-------------------------------------------------.
   V                                                   |
>----+- -p--pathname-- -o--offset-- -m--pathname--offset-+-+---->
     '- -f--filename-------------------------------------'

>--+-----+-------------------------------------------------------><
   '- -y-'
```

This command has an equivalent SQL administration API function.

Element	Purpose	Key considerations
-f *filename*	Indicates that chunk-location information is in a file named *filename*	The file must be a buffered file that already exists. The path name must conform to the operating-system-specific rules for path names. For more information, see Using a File to Specify Chunk-Location Information with the -f Option.
-m	Adds mirroring for an existing dbspace, blobspace, or sbspace	User-data chunks in a mirrored sbspace need not be mirrored. The mirrored chunks should be on a different disk. You must mirror all the chunks at the same time.
-m *pathname offset*	The second time that *pathname* occurs in the syntax diagram, it indicates the disk partition or unbuffered device of the initial chunk of the dbspace, blobspace, or sbspace that performs the mirroring. The second time *offset* appears in the syntax diagram, it indicates the offset to reach the mirrored chunk of the newly mirrored dbspace, blobspace, or sbspace. Also see the entries for *pathname* and *offset* in this table.	None.
-o *offset*	The first time that *offset* occurs in the syntax diagram, it indicates, in kilobytes, the offset into the disk partition or into the unbuffered device to reach the initial chunk of the newly mirrored dbspace, blobspace, or sbspace.	**Restrictions**: Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 4 terabytes. For more information, see allocating raw disk space on UNIX, in the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*.
-p *pathname*	The first time *pathname* occurs in the syntax diagram, it indicates the disk partition or unbuffered device of the initial chunk of the dbspace, blobspace, or sbspace that you want to mirror.	The chunk must be an existing unbuffered device or buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. For path name syntax, see your operating-system documentation.
-y	Causes the database server to automatically respond yes to all prompts	None.
blobspace	Names the blobspace that you want to mirror	Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*. For more information, see the chapter on using mirroring in the *IBM Informix Administrator's Guide*.
dbspace	Names the dbspace that you want to mirror	Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*. For background information, see the chapter on using mirroring in the *IBM Informix Administrator's Guide*.
sbspace	Names the sbspace that you want to mirror	Syntax must conform to the Identifier segment; see *IBM Informix Guide to SQL: Syntax*. For background information, see the chapter on using mirroring in the *IBM Informix Administrator's Guide*.

- Using a File to Specify Chunk-Location Information with the -f Option

Related reference:
add mirror argument: Add a mirror chunk (SQL administration API)
start mirroring argument: Starts storage space mirroring (SQL administration API)

Using a File to Specify Chunk-Location Information with the -f Option

You can create a file that contains the chunk-location information. Then, when you execute **onspaces**, use the **-f** option to indicate to the database server that this information is in a file whose name you specify in ***filename***.

The contents of the file should conform to the following format, with options separated by spaces and each set of primary and mirror chunks on separate lines:

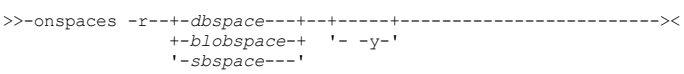
```
primary_chunk_path offset mirror_chunk_path offset
```

If the dbspace that you are mirroring contains multiple chunks, you must specify a mirror chunk for each of the primary chunks in the dbspace that you want to mirror. For an example that enables mirroring for a multichunk dbspace, see starting mirroring for unmirrored dbspaces with **onspaces** in the chapter on using mirroring in the *IBM® Informix® Administrator's Guide*.

onspaces -r: Stop mirroring

Use the **onspaces -r** option to end mirroring for a dbspace, blobspace, or sbspace.

Syntax:



This command has an equivalent SQL administration API function.

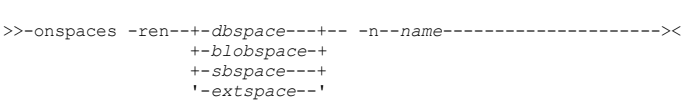
Element	Purpose	Key considerations
-r	Indicates to the database server that mirroring should be ended for an existing dbspace, blobspace, or sbspace	For background information, see the chapter on using mirroring in the *IBM® Informix® Administrator's Guide*.
-y	Causes the database server to respond yes to all prompts automatically	None.
blobspace	Names the blobspace for which you want to end mirroring.	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see the chapter on using mirroring in the *IBM Informix Administrator's Guide*.
dbspace	Names the dbspace for which you want to end mirroring.	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see the chapter on using mirroring in the *IBM Informix Administrator's Guide*.
sbspace	Names the sbspace for which you want to end mirroring	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For background information, see the chapter on using mirroring in the *IBM Informix Administrator's Guide*.

Related reference:
stop mirroring argument: Stops storage space mirroring (SQL administration API)

onspaces -ren: Rename a dbspace, blobspace, sbspace, or extspace

Use the **onspaces -ren** option to rename a dbspace, blobspace, sbspace, or extspace.

Syntax:



This command has an equivalent SQL administration API function.

Element	Purpose	Key considerations

Element	Purpose	Key considerations
-ren	Causes the database server to rename the specified blobspace, dbspace, extspace, or sbspace	**Restrictions**: You can rename a blobspace, dbspace, extspace, or sbspace when the database server is in quiescent mode. For more information, see the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*.
-n *name*	Specifies the new name for the blobspace, dbspace, extspace, or sbspace	**Restrictions**: The blobspace, dbspace, external space, or sbspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the **$** character. For more information, see the chapter on managing disk space in the *IBM Informix Administrator's Guide*. The syntax must conform to the Identifier segment. For more information, see the *IBM Informix Guide to SQL: Syntax*.
blobspace	Names the blobspace to be renamed	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see renaming spaces, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
dbspace	Names the dbspace to be renamed	**Restrictions:** You cannot rename a critical dbspace, such as the root dbspace or a dbspace that contains physical logs. **Additional Information:** If you rename dbspaces that are included in the DATASKIP list, update the DATASKIP configuration parameter with the new names using the **onspaces -f** command. Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see renaming spaces, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
extspace	Names the extspace to be renamed	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see renaming spaces, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.
sbspace	Names the sbspace to be renamed	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see renaming spaces, in the chapter on managing disk space in the *IBM Informix Administrator's Guide*.

- Renaming a dbspace, blobspace, sbspace, or extspace when Enterprise Replication is active
  You can rename a space (dbspace, blobspace, sbspace, or extspace) when Enterprise Replication is active.
- Performing an Archive after Renaming a Space

Related reference:
rename space argument: Rename a storage space (SQL administration API)

Renaming a dbspace, blobspace, sbspace, or extspace when Enterprise Replication is active

You can rename a space (dbspace, blobspace, sbspace, or extspace) when Enterprise Replication is active.

When you put the database server into quiescent mode to rename the space, Enterprise Replication will be disconnected. You can then rename the space. The servers will resynchronize after you put the database server into online mode.

If you want to rename the same space on another server, you must put that server into quiescent mode and rename the space separately. No enforced relationship is propagated between renamed spaces on different ER servers; the same tables can be in different spaces.

If the Enterprise Replication server also participates in High-Availability Data Replication (HDR), you can rename the dbspace on the primary server and it will be automatically propagate to the secondary server. (The secondary server cannot participate in Enterprise Replication.)

Performing an Archive after Renaming a Space

After renaming any space (except extspaces or temporary spaces), perform a level-0 archive of the renamed space and the root dbspace. This will ensure that you can restore the spaces to a state including or following the rename dbspace operation. It is also necessary prior to performing any other type of archive.

onspaces -s: Change status of a mirrored chunk

Use the **onspaces -s** option to change the status of a mirrored chunk in a dbspace, a non-primary chunk within a noncritical dbspace, a blobspace, or an sbspace.

Syntax:

```
>>-onspaces -s--+-dbspace---+-- -p--pathname-- -o--offset------->
```

```
                +-blobspace-+
                '-sbspace---'

>--+- -D-+--+-----+-----------------------------------------><
   '- -O-'  '- -y-'
```

This command has an equivalent SQL administration API function.

Element	Purpose	Key considerations
-D	Indicates that you want to take the chunk down	None.
-o *offset*	Indicates, in kilobytes, the offset into the disk partition or unbuffered device to reach the chunk	**Restrictions**: Unsigned integer. The starting offset must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size.The offset must be a multiple of the page size. The maximum offset is 4 terabytes. For more information, see allocating raw disk space on UNIX, in the chapter on managing disk space in the *IBM® Informix® Administrator's Guide*.
-O	Indicates that you want to restore the chunk and bring it online	None.
-p *pathname*	Indicates the disk partition or unbuffered device of the chunk	The chunk can be an unbuffered device or a buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. For path name syntax, see your operating-system documentation.
-s	Indicates that you want to change the status of a chunk	**Restrictions**: You can only change the status of a chunk in a mirrored pair or a non-primary chunk within a noncritical dbspace. For more information, see changing the mirror status in the *IBM Informix Administrator's Guide*.
-y	Causes the database server to respond yes to all prompts automatically	None.
blobspace	Names the blobspace whose status you want to change	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see changing the mirror status in the *IBM Informix Administrator's Guide*.
dbspace	Names the dbspace whose status you want to change	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For more information, see changing the mirror status in the *IBM Informix Administrator's Guide*.
sbspace	Names the sbspace whose status you want to change	Syntax must conform to the Identifier segment; see the *IBM Informix Guide to SQL: Syntax*. For background information, see changing the mirror status in the *IBM Informix Administrator's Guide*.

Avoid overwriting a chunk

The chunks associated with each Informix® instance are not known to other Informix instances. It is possible to inadvertently create a chunk on a file or device that is allocated as a chunk to another Informix instance, which results in data corruption.

If you attempt to initialize an instance, where the ROOTPATH configuration parameter specifies a file or device that is the root chunk of another instance, the command fails with the following message in the online.log:

```
DISK INITIALIZATION ABORTED: potential instance overwrite detected.
```

To disable this initialization check, set the FULL_DISK_INIT configuration parameter to 1 in your configuration file and try to initialize the instance again. However, this initialization check is restricted to the root chunk. Adding dbspaces or chunks succeeds even when the file or device is allocated to another instance.

create dbspace argument: Create a dbspace (SQL administration API)
create sbspace argument: Create an sbspace (SQL administration API)

The onstat utility

The **onstat** utility reads shared-memory structures and provides statistics about the database server at the time that the command runs.

You can combine multiple **onstat** option flags in a single command. The contents of shared memory might change as the **onstat** output displays. The **onstat** utility does not place any locks on shared memory, so running the utility does not affect performance.

You use SQL administration API commands that are equivalent to **onstat** commands.

- onstat Portal: onstat Utility Commands Sorted by Functional Category
  The information in this topic lists **onstat** commands that are sorted by functional category.
- Monitor the database server status
  To monitor the database server status, view the heading of the **onstat** command.
- onstat command syntax
  The complete syntax for the **onstat** command, including information about the interactive mode and how to have options to execute repeatedly.
- onstat command: Equivalent to the onstat -pu command
  If you invoke **onstat** without any options, the command is interpreted as **onstat -pu** (the **-p** option and the **-u** option).
- onstat - command: Print output header
  All **onstat** output includes a header. The **onstat -** command displays only the output header and the value that is returned from this command indicates the database server mode.
- onstat -- command: Print onstat options and functions
  Use the **onstat --** command to display a listing of all of the **onstat** options and their functions. You cannot combine this option with any other flag.
- Running onstat Commands on a Shared Memory Dump File
  You can run **onstat** commands against a shared memory dump file. The shared memory dump file can be produced explicitly by using the **onstat -o** command. If the DUMPSHMEM configuration parameter is set to 1 or set to 2, the dump file is created automatically at the time of an assertion failure.
- onstat -a command: Print overall status of the database server
  Use the **onstat -a** command to display information about the status of the database server. This command does not display information about all of the onstat options, only about those onstat options used for initial troubleshooting.
- onstat -b command: Print buffer information for buffers in use
  Use the **onstat -b** option to display information about the buffers that are currently in use, including the total number of resident pages in the buffer pool.
- onstat -B command: Prints information about used buffers
  Use the **onstat -B** option to display information about buffers that are not on the free-list.
- onstat -c command: Print ONCONFIG file contents
  Use the **onstat -c** command to display the contents of the ONCONFIG file.
- onstat -C command: Print B-tree scanner information
  Use the **-C** command to display information about the B-tree scanner subsystem and each B-tree scanner thread.
- onstat -d command: Print chunk information
  Use the **onstat -d** command to show information about chunks in each storage space.
- onstat -D command: Print page-read and page-write information
  Use the **onstat -D** command to display page-read and page-write information for the first 50 chunks in each space.
- onstat -f command: Print dbspace information affected by dataskip
  Use the **-f** command to list the dbspaces that the dataskip feature currently affects.
- onstat -F command: Print counts
  Use the **onstat -F** command to display a count for each type of write that flushes pages to disk.
- onstat -g monitoring options
  The options that you can use with **onstat -g** command are used for support and debugging only. You can include only one of these options in the **onstat -g** command.
- onstat -G command: Print TP/XA transaction information
  Use the **onstat -G** command to display information about global transactions generated through the TP/XA library.
- onstat -h command: Print buffer header hash chain information
  Use the **onstat -h** command to display information about the buffer header hash chains (sometimes called "hash buckets") that are used to access pages in each buffer pool.
- onstat -i command: Initiate interactive mode
  Use the **onstat -i** command to put the **onstat** utility in the interactive mode.
- onstat -j command: Provide onpload status information
  Use the **onstat -j** command to provide information about the status of an **onpload** job.
- onstat -k command: Print active lock information
  Use the **onstat -k** command to print information about active locks, including the address of the lock in the lock table.
- onstat -l command: Print physical and logical log information
  Use the **onstat -l** command to display information about the physical logs, logical logs, and temporary logical logs.
- onstat -L command: Print the number of free locks
  Use the **onstat -L** command to print the number of free locks on a lock-free list.
- onstat -m command: Print recent system message log information
  Use the **onstat -m** command to display the 20 most recent lines of the system message log.
- onstat -o command: Output shared memory contents to a file
  Use the **onstat -o** command to write the contents of shared memory to a specified file for later analysis. If you do not specify an output file, a file named **onstat.out** is created in the current directory.
- onstat -p command: Print profile counts
  Use the **onstat -p** command to display information about profile counts either since you started the database server or since you ran the **onstat -z** command.
- onstat -P command: Print partition information
  Use the **onstat -P** command to display the partition number and the pages in the buffer pool for all of the partitions.
- onstat -r command: Repeatedly print selected statistics
  Use the **onstat -r** command to repeatedly print the statistics for other options specified in the command at specified intervals.
- onstat -R command: Print LRU, FLRU, and MLRU queue information
  Use the **onstat -R** command to display detailed information about the LRU queues, FLRU queues, and MLRU queues. For each queue, the **onstat -R** command displays the number of buffers in the queue and the number and percentage of buffers that have been modified.
- onstat -s command: Print latch information
  Use the **onstat -s** command to display general latch information, including the resource that the latch controls.
- onstat -t and onstat -T commands: Print tblspace information
  Use the **onstat -t** command to display tblspace information for active tblspaces. Use the **onstat -T** command to display tblspace information for all tblspaces.
- onstat -u command: Print user activity profile
  Use the **onstat -u** command to display a profile of user activity.

- onstat -x command: Print database server transaction information
  Use the **onstat -x** command to display transaction information on the database server.
- onstat -X command: Print thread information
  Use the **onstat -X** command to obtain precise information about the threads that are waiting for buffers.
- onstat -z command: Clear statistics
  Use the **onstat -z** command to clear database server statistics, including statistics that relate to Enterprise Replication, and set the profile counts to 0.
- Return codes on exiting the onstat utility
  The **onstat** utility displays a set of return codes when you exit the utility.

onstat argument: Monitor the database server (SQL administration API)

onstat Portal: onstat Utility Commands Sorted by Functional Category

The information in this topic lists **onstat** commands that are sorted by functional category.

Each category represents a different IBM® Informix® feature for which **onstat** commands are useful for providing troubleshooting and performance enhancement information. Commands that appear in **bold** typeface are especially useful for providing troubleshooting information. Certain **onstat** commands are specific to one category, while others provide more general information and are listed in more than one category.

Category List

Determine the appropriate category from the following list, then follow the link to the **onstat** options for that category.

onstat Utility Archive Information Options

Use the following **onstat** options to display information about archives and restores.

Table 1. onstat Utility Archive Information Options

Commands	Reference
onstat -D	Prints chunk I/O activity. Prints dbspace read/write activity for monitoring restore progress. onstat -D command: Print page-read and page-write information
onstat -g arc	Prints the last committed and any ongoing backups for each dbspace. onstat -g arc command: Print archive status

onstat Utility Cache Information Options

Use the following **onstat** options to display information about caches and cached data, including buffer pools.

Table 2. onstat Utility Cache Information Options

Commands	Reference
onstat -b	Prints buffer pages in use. onstat -b command: Print buffer information for buffers in use
onstat -B	Prints information about used buffers. onstat -B command: Prints information about used buffers

Commands	Reference
onstat -F	Prints state of buffer queue cleaners and I/O. onstat -F command: Print counts
onstat -g cac	Prints summary and detailed information about all memory caches or about the specified cache. onstat -g cac command: Print information about caches
onstat -g dic	Prints data dictionary cache, containing system catalog data for tables. Prints one line of information for each table that is cached in the shared-memory dictionary. For more information, see your *IBM Informix Performance Guide*. onstat -g dic command: Print table information
onstat -g dsc	Prints table distribution statistics for the optimizer. onstat -g dsc command: Print distribution cache information.
onstat -g prc	Prints the stored procedure (SPL) routine cache. Prints information about SPL routine cache. onstat -g prc command: Print sessions using UDR or SPL routines
onstat -g ssc	Prints the number of times that the database server reads the SQL statement in the cache. Displays the same output as **onstat -g cac**. For more information, see improving query performance in the *IBM Informix Performance Guide*. onstat -g ssc command: Print SQL statement occurrences
onstat -g vpcache	Prints CPU virtual processor memory cache. onstat -g vpcache command: Print CPU virtual processor and tenant virtual processor private memory cache statistics
onstat -h	Prints buffer hash chain information. onstat -h command: Print buffer header hash chain information
onstat -p	Prints global (server) information regarding the effectiveness of buffer pool caching. onstat -p command: Print profile counts
onstat -X	Prints threads that are waiting for buffers. onstat -X command: Print thread information

onstat Utility Compression Options

Use the following **onstat** options to print compression information.

Table 3. onstat Utility Compression Options

Commands	Reference
onstat -g dsk	Prints progress of currently running compression operations. onstat -g dsk command: Print the progress of the currently running compression operation
onstat -g ppd	Prints partition compression dictionary information. onstat -g ppd command: Print partition compression dictionary information

onstat Utility Debugging Options

Use the following **onstat** options to display information that is useful for debugging problems with the server.

Table 4. onstat Utility Debugging Options

Commands	Reference
onstat -g dmp	Prints raw memory at a specified address for a number of given bytes. onstat -g dmp command: Print raw memory
onstat -g src	Searches for patterns in shared memory. Note that memory is byte-swapped on Intel platforms. onstat -g src command: Patterns in shared memory
onstat -o	Prints shared memory contents to a file. onstat -o command: Output shared memory contents to a file.

onstat Utility Enterprise Replication Options

Use the following **onstat** options to track Enterprise Replication statistics and to provide troubleshooting information. For additional information about Enterprise Replication see the **cdr view** and **cdr view profile** commands that are described in the .

Table 5. onstat Utility Enterprise Replication Options

Commands	Reference
onstat -g cat	Prints information from the Enterprise Replication global catalog. The global catalog contains a summary of information about the defined servers, replicates, and replicate sets on each of the servers within the enterprise. onstat -g cat: Print ER global catalog information
onstat -g cdr	Prints the output for all of the Enterprise Replication statistics commands. onstat -g cdr: Print ER statistics
onstat -g cdr config	Prints Enterprise Replication configuration parameters and environment variables. onstat -g cdr config: Print ER settings
onstat -g ddr	Prints status of Enterprise Replication components that read and process log records. onstat -g ddr: Print status of ER log reader
onstat -g dss	Prints activity of individual data sync (transaction processing) threads. onstat -g dss: Print statistics for data sync threads
onstat -g dtc	Prints delete table cleaner activity. Deleted or updated rows that are placed in the delete table are purged at intervals. onstat -g dtc: Print statistics about delete table cleaner
onstat -g grp	Prints Enterprise Replication grouper statistics. The grouper evaluates the log records, rebuilds the individual log records into the original transaction, packages the transaction, and queues the transaction for transmission. onstat -g grp: Print grouper statistics
onstat -g nif	Prints network interface statistics. Shows the state of the network interface, servers, and data transfer among servers. onstat -g nif: Print statistics about the network interface
onstat -g que	Prints statistics for the high-level queue interface (which is common to all of the queues of the Enterprise Replication Queue Manager). onstat -g que: Print statistics for all ER queues
onstat -g rcv	Prints receive manager statistics. onstat -g rcv: Print statistics about the receive manager
onstat -g rep	Prints events that are in the queue for the schedule manager. onstat -g rep: Prints the schedule manager queue
onstat -g rqm	Prints statistics and contents of the low-level queues (send queue, receive queue, ack send queue, sync send queue, and control send queue) managed by the Reliable Queue Manager (RQM). onstat -g rqm: Prints statistics for RQM queues
onstat -g sync	Prints synchronization status. onstat -g sync: Print statistics about synchronization

onstat Utility High-Availability Replication Options

Use the following **onstat** options to monitor high-availability cluster environments and the Connection Manager.

Table 6. onstat Utility High-Availability Replication Options

Commands	Reference
onstat -g cluster	Prints high-availability cluster information. onstat -g cluster command: Print high-availability cluster information
onstat -g cmsm	Prints Connection Manager information. onstat -g cmsm command: Print Connection Manager information
onstat -g dri	Prints data-replication information. See *Monitoring High-Availability Data-Replication status* in the *IBM Informix Administrator's Guide*. onstat -g dri command: Print high-availability data replication information.
onstat -g ipl	Prints index page logging status. onstat -g ipl command: Print index page logging status information
onstat -g laq	Prints information about log recovery apply queues. onstat -g laq command: Print log apply queues
onstat -g proxy	Prints proxy distributors for high-availability. onstat -g proxy command: Print proxy distributor information

Commands	Reference
onstat -g rss	Prints remote stand-alone server (RSS) information. onstat -g rss command: Print RS secondary server information
onstat -g sds	Prints shared disk secondary (SDS) server information. onstat -g sds command: Print SD secondary server information
onstat -g smx	Prints Server Multiplexer Group (SMX) connections in high-availability environments. Prints data transfer statistics and encryption status. onstat -g smx command: Print multiplexer group information

onstat Utility Informix Warehouse Accelerator Options

Use the following **onstat** options to display information that is exchanged between the database server and the Informix Warehouse Accelerator.

Table 7. onstat Utility Informix Warehouse Accelerator options

Commands	Reference
onstat -g aqt	Prints information about the data marts and the associated accelerated query tables (AQTs). onstat -g aqt command: Print data mart and accelerated query table information.

onstat Utility I/O Options

Use the following **onstat** options to track input and output (read and write) activity.

Table 8. onstat Utility I/O Options

Commands	Reference
onstat -D	Prints chunk I/O activity. onstat -D command: Print page-read and page-write information
onstat -g cpu	Prints runtime statistics for each thread. onstat -g cpu: Print runtime statistics
onstat -g ioa	Prints combined information from **onstat -g ioq** (queues), **onstat -g iov** (virtual processors), and **onstat -g iob** (big buffer). onstat -g ioa command: Print combined onstat -g information
onstat -g iob	Prints the big buffer usage summary. onstat -g iob command: Print big buffer use summary
onstat -g iof	Prints I/O statistics by file or chunk. This option is similar to the **onstat -D** option, but also displays information about non-chunk, temporary, and sort-work files. onstat -g iof command: Print asynchronous I/O statistics
onstat -g iog	Prints AIO global information. onstat -g iog command: Print AIO global information
onstat -g ioq	Prints queue read/write statistics and queue length. onstat -g ioq command: Print I/O queue information. Also see the *IBM Informix Performance Guide*.
onstat -g iov	Prints asynchronous I/O statistics by virtual processor. onstat -g iov command: Print AIO VP statistics
onstat -p	Prints global disk activity, including sequential scans. onstat -p command: Print profile counts

onstat Utility Locks and Latches Options

Use the following **onstat** options to display information about locks.

Table 9. onstat Utility Locks and Latches Options

Commands	Reference
onstat -k	Prints information about active locks. onstat -k command: Print active lock information
onstat -L	Prints the number of locks on a lock free list. onstat -L command: Print the number of free locks

Commands	Reference
onstat -p	Prints global statistics on lock requests, lock waits, and latch waits. onstat -p command: Print profile counts
onstat -s	Prints latch (mutex) information. onstat -s command: Print latch information

onstat Utility Logs Options

Use the following **onstat** options to monitor logical and physical logs.

Table 10. onstat Utility Logs Options

Commands	Reference
onstat -g ipl	Prints index page logging information in high-availability environments. onstat -g ipl command: Print index page logging status information
onstat -l	Prints status of physical and logical logs, and log buffering. onstat -l command: Print physical and logical log information

onstat Utility Memory Options

Use the following **onstat** options to monitor the various aspects of server memory allocation and use.

Table 11. onstat Utility Memory Options

Commands	Reference
onstat -g afr	Prints allocated memory fragments for a specified session or shared-memory pool. To obtain the pool name, see the **onstat -g mem** option. onstat -g afr command: Print allocated memory fragments
onstat -g ffr (*pool name session ID*)	Prints free fragments for a session or shared memory pool. onstat -g ffr command: Print free fragments
onstat -g lmm	Prints information about automatic low memory management settings and recent activity: onstat -g lmm command: Print low memory management information
onstat -g mem	Prints session or pool virtual shared memory statistics. onstat -g mem command: Print pool memory statistics
onstat -g mgm	Prints Memory Grant Manager (parallel and sort operations) resource information. onstat -g mgm command: Print MGM resource information. Also see the *IBM Informix Performance Guide*.
onstat -g nbm	Prints block map for non-resident segments. onstat -g nbm command: Print a block bit map
onstat -g rbm	Prints block map for resident segment. onstat -g rbm command: Print a block map of shared memory
onstat -g seg	Prints memory segment statistics. onstat -g seg command: Print shared memory segment statistics. Also see the *IBM Informix Administrator's Guide*.
onstat -g ses	Prints session information, including memory breakdown. For detailed information, use: **onstat -g ses** *session_id* onstat -g ses command: Print session-related information Also see the *IBM Informix Performance Guide*
onstat -g stm	Prints SQL statement memory use. onstat -g stm command: Print SQL statement memory usage
onstat -g stq	Prints stream queue buffers. onstat -g stq command: Print queue information
onstat -g ufr	Prints memory pool fragments for a session or shared memory pool in use. onstat -g ufr command: Print memory pool fragments
onstat -R	Prints buffer pool queues and their status. onstat -R command: Print LRU, FLRU, and MLRU queue information

onstat Utility Network Options

Use the following **onstat** options to monitor shared memory and network connection services.

Table 12. onstat Utility Network Options

Commands	Reference
onstat -g imc	Prints information about Informix MaxConnect instances that are connected to the database server. If Informix MaxConnect is not connected to the database server, this command displays `No MaxConnect servers are connected`.
onstat -g nsc	Prints shared-memory status by *client id*. If *client id* is omitted, all client status areas are displayed. This command prints the same status data as the **nss** command. onstat -g nsc command: Print current shared memory connection information
onstat -g nsd	Prints network shared-memory data for poll threads. onstat -g nsd command: Print poll threads shared-memory data
onstat -g nss	Prints network shared-memory status by *session id*. If *session id* is omitted, all session status areas are displayed. This command prints the same status data as the **onstat -g nsc** command. onstat -g nss command: Print shared memory network connections status
onstat -g nta	Prints combined network statistics from **onstat -g ntd**, **onstat -g ntm**, **onstat -g ntt**, and **onstat -g ntu**. If Informix MaxConnect is installed, this command prints statistics that you can use to tune Informix MaxConnect performance.
onstat -g ntd	Prints network statistics by service. onstat -g ntd command: Print network statistics
onstat -g ntm	Prints network mail statistics. onstat -g ntm command: Print network mail statistics
onstat -g ntt	Prints network user times. onstat -g ntt command: Print network user times
onstat -g ntu	Prints network user statistics. onstat -g ntu command: Print network user statistics

onstat Utility Performance Checks (First Tier)

Use the following **onstat** options to monitor performance and to check for performance impediments. Use the second-tier **onstat** options (and other **onstat** commands) to further narrow the problem.

Table 13. onstat Utility Performance Checks (First Tier)

Commands	Reference
onstat -c	Prints server configuration. onstat -c command: Print ONCONFIG file contents
onstat -D	Prints chunk I/O. onstat -D command: Print page-read and page-write information
onstat -g ath	Prints status and statistics for all threads. The **sqlexec** thread is a client session thread. The **rstcb** value corresponds to the user field of the **onstat -u** command. onstat -g ath command: Print information about all threads. For information about using **onstat -g ath** to print Enterprise Replication threads, see the .
onstat -g ckp	Prints checkpoint history and display configuration recommendations. onstat -g ckp command: Print checkpoint history and configuration recommendations
onstat -g cpu	Prints runtime statistics for each thread. onstat -g cpu: Print runtime statistics
onstat -g ioq	Prints pending I/O operations for the *queue name*. onstat -g ioq command: Print I/O queue information
onstat -p	Prints global server performance profile. onstat -p command: Print profile counts
onstat -u	Prints status and statistics for user threads. If a thread is waiting for a resource, this command identifies the type (flags field) and address (wait field) of the resource. onstat -u command: Print user activity profile

onstat Utility Performance Checks (Second Tier)

Use the following **onstat** options to identify performance impediments.

Table 14. onstat Utility Performance Checks (Second Tier)

Commands	Reference

Commands	Reference
onstat -b	Prints active buffers. onstat -b command: Print buffer information for buffers in use
onstat -g act	Prints active threads. onstat -g act command: Print active threads
onstat -g glo	Prints virtual processors and their operating system processes (**oninit** processes). Prints virtual processor CPU use. On Windows, the virtual processors are operating system threads, and the values in the **pid** field are thread IDs. onstat -g glo command: Print global multithreading information
onstat -g mgm	Prints Memory Grant Manager resource information. onstat -g mgm command: Print MGM resource information
onstat -g rah	Prints read-ahead request information onstat -g rah command: Print read-ahead request statistics
onstat -g rea	Prints threads in the ready queue that are waiting for CPU resources. onstat -g rea command: Print ready threads
onstat -g seg	Prints shared-memory-segment statistics. This option shows the number and size of shared-memory segments that are allocated to the database server. onstat -g seg command: Print shared memory segment statistics.
onstat -g wai	Prints waiting threads; all threads that are waiting for mutex or condition, or yielding. onstat -g wai command: Print wait queue thread list
onstat -k	Prints active locks. onstat -k command: Print active lock information

onstat Utility Table Options

Use the following **onstat** options to display information about table status and table statistics.

Table 15. onstat Utility Table Options

Commands	Reference
onstat -g buf	Prints buffer pool profile information. onstat -g buf command: Print buffer pool profile information
onstat -g lap	Prints information about the status of currently active light appends (writes bypassing the buffer pool). onstat -g lap command: Print light appends status information
onstat -g opn	Prints open partitions (tables). onstat -g opn command: Print open partitions
onstat -g ppf	Prints partition profile (activity data) for the specified partition number or prints profiles for all partitions. onstat -g ppf command: Print partition profiles
onstat -g scn	Prints information about the progress of a scan, based on rows scanned on compressed tables, tables with rows that are larger than a page, and tables with VARCHAR, LVARCHAR, and NVARCHAR data, and identifies whether a scan is a light or bufferpool scan. onstat -g scn command: Print scan information
onstat -P	Prints table and B-tree pages in the buffer pool, listed by partition (table). onstat -P command: Print partition information
onstat -t **onstat -T**	Prints basic tblspace (partition) information for active (t) or all (T) tblspaces. onstat -t and onstat -T commands: Print tblspace information

onstat Utility Thread Options

Use the following **onstat** options to display the status and activity of threads.

Table 16. onstat Utility Thread Options

Commands	Reference
onstat -g act	Prints active threads. This output is included in **onstat -g ath** output. onstat -g act command: Print active threads

Commands	Reference
onstat -g ath	Prints all threads. onstat -g ath command: Print information about all threads. For information about using **onstat -g ath** to print Enterprise Replication threads, see the .
onstat -g bth	Displays the dependencies between blocking and waiting threads. onstat -g bth and -g BTH: Print blocked and waiting threads
onstat -g BTH	Displays session and stack information for the blocking threads. onstat -g bth and -g BTH: Print blocked and waiting threads
onstat -g cpu	Prints runtime statistics for each thread. onstat -g cpu: Print runtime statistics
onstat -g rea	Prints ready threads (threads that are waiting for CPU resources). This output is included in the **onstat -g ath** output. onstat -g rea command: Print ready threads.
onstat -g sle	Prints information about threads that are sleeping for a specified time. Does not include threads that are sleeping forever. onstat -g sle command: Print all sleeping threads
onstat -g stk	Prints the stack of a specified thread or prints stacks for all threads. onstat -g stk command: Print thread stack
onstat -g sts	Prints maximum and current stack use per thread. onstat -g sts command: Print stack usage for each thread
onstat -g tpf	Prints thread activity statistics. onstat -g tpf command: Print thread profiles
onstat -g wai	Prints waiting (idle, sleeping, and waiting) threads. Included in **onstat -g ath** output. onstat -g wai command: Print wait queue thread list
onstat -g wst	Prints wait statistics for threads. onstat -g wst command: Print wait statistics for threads

onstat Utility User/Session Options

Use the following **onstat** options to display information about the user environment and active sessions.

Table 17. onstat Utility User/Session Options

Commands	Reference
onstat -g env	Prints the values of environment variables the database server is using. onstat -g env command: Print environment variable values
onstat -g his	Prints SQL tracing information. onstat -g his command: Print SQL trace information
onstat -g pqs	Prints operators that are used in currently running SQL queries. onstat -g pqs command: Print operators for all SQL queries
onstat -g ses	Prints summary information for all active sessions or detailed information for individual sessions. onstat -g ses command: Print session-related information
onstat -g spf	Prints prepared statement profiles for all active sessions. onstat -g spf: Print prepared statement profiles
onstat -g sql	Prints SQL information for all active sessions or detailed SQL information for individual sessions. onstat -g sql command: Print SQL-related session information
onstat -G	Prints global transactions. onstat -G command: Print TP/XA transaction information
onstat -u	Prints status of user threads and their global read/write statistics. onstat -u command: Print user activity profile
onstat -x	Prints information about transactions. onstat -x command: Print database server transaction information

onstat Utility Virtual Processor Options

Use the following **onstat** options to display information and statistics for virtual processors.

Table 18. onstat Utility Virtual Processor Options

Commands	Reference
onstat -g glo	Prints global multithreading information and global statistics for virtual processor classes and individual virtual processors. On Windows, the virtual processors are operating system threads, and the values in the **pid** field are thread IDs. onstat -g glo command: Print global multithreading information
onstat -g sch	Prints the number of semaphore operations, spins, and busy waits for each virtual processor. On Windows, the virtual processors are operating system threads, and the values in the **pid** field are thread IDs. onstat -g sch command: Print VP information

onstat Utility Waiting Options

Use the following **onstat** options to display information about wait conditions for threads.

Table 19. onstat Utility Waiting Options

Commands	Reference
onstat -g con	Prints IDs of threads that are waiting for conditions. **onstat -g ath** to print thread information. See onstat -g con command: Print condition and thread information
onstat -g lmx	Prints all locked mutexes. onstat -g lmx command: Print all locked mutexes
onstat -g qst	Prints queue-wait statistics for mutex and condition queues. onstat -g qst command: Print wait options for mutex and condition queues
onstat -g rwm	Prints read/write mutexes. onstat -g rwm command: Print read and write mutexes
onstat -g spi	Prints spin locks with long spins and spin lock statistics. onstat -g spi command: Print spin locks with long spins
onstat -g wai	Prints waiting threads; all threads that are waiting for mutex or condition, or yielding. onstat -g wai command: Print wait queue thread list
onstat -g wmx	Prints all mutexes with waiters. onstat -g wmx command: Print all mutexes with waiters

Other Useful onstat Utility Options

Table 20. Other Useful onstat Utility Options

Commands	Reference
onstat -	Prints **onstat** header; includes engine version, status (online, Quiescent, and so on), elapsed time since initialization, and memory footprint. onstat - command: Print output header
onstat –	Prints **onstat** usage options. onstat -- command: Print onstat options and functions
onstat *options infile*	Print **onstat** output using a shared memory dump (infile) as input. Running onstat Commands on a Shared Memory Dump File
onstat -a	Prints collective **onstat** outputs. onstat -a command: Print overall status of the database server
onstat -c	Prints the server configuration file. onstat -c command: Print ONCONFIG file contents
onstat -C	Prints B-tree index scanner information (shows statistics about index cleaning). onstat -C command: Print B-tree scanner information
onstat -d	Prints chunk information. onstat -d command: Print chunk information
onstat -f	Prints dbspaces configured for dataskip. onstat -f command: Print dbspace information affected by dataskip
onstat -g all	Prints diagnostic information. onstat -g all command: Print diagnostic information

Commands	Reference
onstat -g cfg	Prints a list of configuration parameters with their current values. onstat -g cfg command: Print the current values of configuration parameters
onstat -g dbc	Prints statistics about dbScheduler and dbWorker threads. onstat -g dbc command: Print dbScheduler and dbWorker thread statistics
onstat -g dis	Prints a list of database servers, their status, directory location, configuration information, and host name. onstat -g dis command: Print database server information
onstat -g dll	Prints a list of dynamic libraries that are loaded. onstat -g dll command: Print dynamic link library file list
onstat -g osi	Prints information about operating system resources and parameters. onstat -g osi: Print operating system information
onstat -g pos	Prints values from $INFORMIXDIR/etc/.infos.servernum file, which are used by clients such as **onmode** for shared memory connections to the server. **onmode -R** rebuilds the $INFORMIXDIR/etc/.infos.servernum file. onstat -g pos command: Print file values
onstat -g smb	Prints detailed information about sbspaces. onstat -g smb command: Print sbspaces information
onstat -g sym	Prints symbol table information for the **oninit** utility. onstat -g sym command: Print symbol table information for the oninit utility
onstat -i	Changes **onstat** mode to interactive. onstat -i command: Initiate interactive mode
onstat -j	Prints information about the status of an **onpload** job. onstat -j command: Provide onpload status information
onstat -m	Prints message log contents. onstat -m command: Print recent system message log information
onstat -r	Prints repetitive **onstat** execution. onstat -r command: Repeatedly print selected statistics
onstat -z	Resets the accumulated statistics to zero. onstat -z command: Clear statistics

Monitor the database server status

To monitor the database server status, view the heading of the **onstat** command.

Whenever the database server is blocked, **onstat** displays the following line after the banner line:

```
Blocked: reason
```

The variable *reason* can be one or more of the following values.

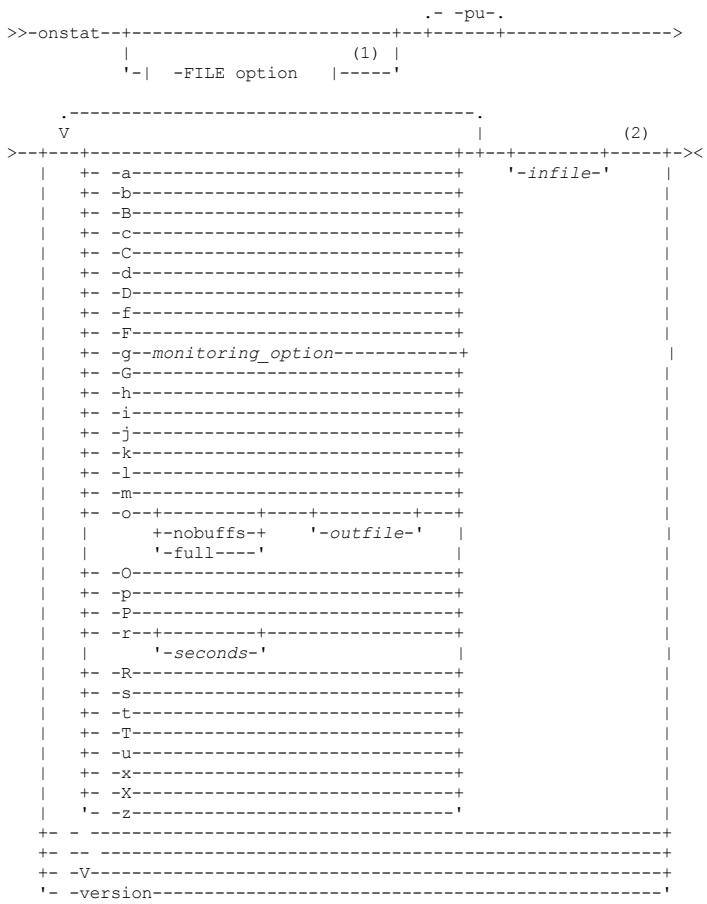
Reason	Description
ADMINISTRATION	Database is in administration mode
ARCHIVE	Ongoing storage-space backup
ARCHIVE_EBR	Blocked for External Backup and Recovery.
CHG_PLOG	Blocked while physical log is being changed.
CKPT	Checkpoint
CKPT INP	Interval checkpoint in progress
DBS_DROP	Dropping a dbspace
DDR	Discrete data replication
DYNAMIC_LOG	Log file is being added dynamically
DYNAMIC_LOG_FOR_ER	Log file is being added dynamically in ER setup
FREE_LOG	Log file is being freed
HA_CONV_STD	Blocked while High Availability server is being converted to standard server.
HA_FAILOVER	Blocked while High Availability server failover being processed.

HANG_SYSTEM	Database server failure
LAST_LOG_RESERVED4BACKUP	Waiting for last available log to be backed up
LBU	Logs full high-watermark
LOG_DROP	Log file is being dropped
LONGTX	Long transaction
MEDIA_FAILURE	Media failure
OVERRIDE_DOWN_SPACE	Waiting to override down dbspace setting because the ONDBSPACEDOWN onconfig parameter is set to WAIT

In this table, the value CHKP INP does not indicate that the database server is blocked, but that a nonblocking interval checkpoint is in progress while the buffer pool is being flushed. This CHKP INP value appears in the status line of **onstat** output until all pages in the shared-memory buffer pool have been written to disk. For information about setting interval checkpoints to flush the buffer pool, see the CKPTINTVL configuration parameter.

onstat command syntax

The complete syntax for the **onstat** command, including information about the interactive mode and how to have options to execute repeatedly.



Notes:

1. See The -FILE option.
2. Only one occurrence of each item is allowed. More than one option can be specified on a single **onstat** command invocation.

Element	Purpose	Key Considerations
-	Displays the output header only.	See onstat - command: Print output header.
--	Displays a listing of all **onstat** options and their functions	See onstat -- command: Print onstat options and functions. This option cannot be combined with any other **onstat** option.
-a	Interpreted as **onstat -cuskbtdlp**. Displays output in that order.	See onstat -a command: Print overall status of the database server.
-b	Displays information about buffers currently in use, including number of resident pages in the buffer pool	See onstat -b command: Print buffer information for buffers in use.

Element	Purpose	Key Considerations
-B	Obtains information about all database server buffers, not just buffers currently in use.	See onstat -B command: Prints information about used buffers.
-c	Displays the ONCONFIG file: • $INFORMIXDIR/etc/$ONCONFIG for UNIX • %INFORMIXDIR%\etc\ %ONCONFIG% for Windows	See onstat -c command: Print ONCONFIG file contents.
-C	Prints B-tree scanner information	See onstat -C command: Print B-tree scanner information.
-d	Displays information for chunks in each storage space	See onstat -d command: Print chunk information.
-D	Displays page-read and page-write information for the first 50 chunks in each dbspace	See onstat -D command: Print page-read and page-write information.
-f	Lists the dbspaces currently affected by the DATASKIP feature	See onstat -f command: Print dbspace information affected by dataskip.
-F	Displays a count for each type of write that flushes pages to disk	See onstat -F command: Print counts.
-g *option*	Prints monitoring option	See onstat -g monitoring options.
-G	Prints global transaction IDs	See onstat -G command: Print TP/XA transaction information.
-h	Provides information on the buffer header hash chains	See onstat -h command: Print buffer header hash chain information.
-i	Puts the **onstat** utility into interactive mode	See onstat -i command: Initiate interactive mode.
-j	Prints the interactive status of the active **onpload** process	See onstat -j command: Provide onpload status information.
-k	Displays information about active locks	See onstat -k command: Print active lock information.
-l	Displays information about physical and logical logs, including page addresses	See onstat -l command: Print physical and logical log information.
-m	Displays the 20 most recent lines of the database server message log	Output from this option lists the full pathname of the message-log file and the 20 file entries. A date-and-time header separates the entries for each day. A time stamp prefaces single entries within each day. The name of the message log is specified as MSGPATH in the ONCONFIG file. See onstat -m command: Print recent system message log information.
-o	Saves a copy of the shared-memory segments to *outfile*	See onstat -o command: Output shared memory contents to a file.
-p	Displays profile counts.	See onstat -p command: Print profile counts.
-P	Displays for all partitions the partition number and the break-up of the buffer-pool pages that belong to the partition	See onstat -P command: Print partition information.
-pu	If you invoke **onstat** without any options, the command is interpreted as **onstat -pu** (-p option and -u option). Displays profile counts and prints a profile of user activity	See onstat -p command: Print profile counts and onstat -u command: Print user activity profile.
-r *seconds*	Repeats the accompanying **onstat** options after a wait time specified in *seconds* between each execution	See onstat -r command: Repeatedly print selected statistics.
-R	Displays detailed information about the LRU queues, FLRU queues, and MLRU queues	See onstat -R command: Print LRU, FLRU, and MLRU queue information.
-s	Displays general latch information	See onstat -s command: Print latch information.
-t	Displays tblspace information, including residency state, for active tblspaces	See onstat -t and onstat -T commands: Print tblspace information.
-T	Displays tblspace information for all tblspaces	See onstat -t and onstat -T commands: Print tblspace information.
-u	Prints a profile of user activity	See onstat -u command: Print user activity profile.
-**V**	Displays the software version number and the serial number. This option cannot be combined with any other **onstat** option.	See Obtaining utility version information.
-**version**	Displays the build version, host, OS, number and date, as well as the GLS version. This option cannot be combined with any other **onstat** option.	See Obtaining utility version information.
-x	Displays information about transactions	See onstat -x command: Print database server transaction information.
-X	Obtains precise information about the threads that are sharing and waiting for buffers	See onstat -X command: Print thread information.
-z	Sets the profile counts to 0	See onstat -z command: Clear statistics.
infile	Specifies a source file for the **onstat** command	This file must include a previously stored shared-memory segment that you created with the **onstat -o** command. For instructions on how to create the *infile* with **onstat -o**, see onstat -o command: Output shared memory contents to a file. For information about running **onstat** on the source file, see Running onstat Commands on a Shared Memory Dump File.

Interactive execution

To put the **onstat** utility in interactive mode, use the -i option. Interactive mode allows you to enter multiple options, one after the other, without exiting the program. For information on using interactive mode, see onstat -i command: Initiate interactive mode.

Continuous onstat command execution

Use the **onstat -r** option combined with other **onstat** options to cause the other options to execute repeatedly at a specified interval. For information, see onstat -r command: Repeatedly print selected statistics.

onstat command: Equivalent to the onstat -pu command

If you invoke **onstat** without any options, the command is interpreted as **onstat -pu** (the **-p** option and the **-u** option).

Syntax:

```
>>-onstat-----------------------------------------------------><
```

onstat - command: Print output header

All **onstat** output includes a header. The **onstat -** command displays only the output header and the value that is returned from this command indicates the database server mode.

Syntax:

```
>>-onstat-- - ------------------------------------------------><
```

The header takes the following form:

```
Version--Mode (Type)--(Checkpnt)--Up Uptime--Sh_mem Kbytes
```

Version
: Is the product name and version number

Mode
: Is the current operating mode.

(Type)
: If the database server uses High-Availability Data Replication, indicates whether the type is primary or secondary
If the database server is not involved in data replication, this field does not appear. If the type is primary, the value `P` appears. If the type is secondary, the value `S` appears.

(Checkpnt)
: Is a checkpoint flag
If it is set, the header might display two other fields after the mode if the timing is appropriate:

(CKPT REQ)
: Indicates that a user thread has requested a checkpoint

(CKPT INP)
: Indicates that a checkpoint is in progress. During the checkpoint, access is limited to read only. The database server cannot write or update data until the checkpoint ends

Uptime
: Indicates how long the database server has been running
If the system time is manually changed to the past and the server startup time is later than the current system time, the uptime is not available. In this situation, the header displays the text `Uptime Unavailable`.

Sh_mem
: Is the size of database server shared memory, expressed in kilobytes

The following is a sample header for the database server:

```
Informix Version 14.10.UC1--On-Line--Up 15:11:41--9216 Kbytes
```

From xC5 onwards, the header also includes a datetime stamp in the format: **<year>-<month>-<day> <hour>:<minute>:<second>**

```
IBM Informix Dynamic Server Version 14.10.FC5 -- On-Line -- Up 00:00:22 -- 54180 Kbytes
2020-12-17 19:15:15
```

If the database server is blocked, the **onstat** header output includes an extra line. For information about status codes in that line, see Monitor the database server status.

Return codes

When you exit the **onstat** utility, there are several useful codes that are displayed. See Return codes on exiting the onstat utility.

onstat -- command: Print onstat options and functions

Use the **onstat --** command to display a listing of all of the **onstat** options and their functions. You cannot combine this option with any other flag.

Syntax:

```
>>-onstat-- ----------------------------------------------><
```

Running onstat Commands on a Shared Memory Dump File

You can run **onstat** commands against a shared memory dump file. The shared memory dump file can be produced explicitly by using the **onstat -o** command. If the DUMPSHMEM configuration parameter is set to 1 or set to 2, the dump file is created automatically at the time of an assertion failure.

Syntax:

```
>>-onstat--options--infile-------------------------------------><
```

When using the command line, enter the source file as the final argument. The following example prints information about all threads for the shared memory dump contained in the file named `onstat.out`, rather than attempting to attach to the shared memory of a running server.

```
onstat -g ath onstat.out
```

For instructions on how to create the memory dump file with **onstat -o**, see onstat -o command: Output shared memory contents to a file.

Running onstat Commands on a Shared Memory Dump File Interactively

Use **onstat -i** (interactive mode) to run more than one **onstat** command against a dump file. Interactive mode can save time because the file is read only once. In command-line mode, each command reads the file.

The following example reads the shared memory dump file and enters interactive mode. Other **onstat** commands can be executed against the dump file in the normal interactive fashion.

```
onstat -i source_file
```

For information about interactive mode, see onstat -i command: Initiate interactive mode.

Running onstat Commands on a Shared Memory Dump File Created Without a Buffer Pool

Certain **onstat** commands have different output when you run them on a dump file created without the buffer pool (created with **onstat -o nobuffs** or with the DUMPSHMEM configuration parameter set to 2):

- If you run **onstat -B** on a dump file created without the buffer pool, the output will display `0` in the `memaddr`, `nslots`, and `pgflgs` columns.
- If you run **onstat -g seg** on a dump file created without the buffer pool, the output will show both the original and nobuffs resident segment size.
- If you run **onstat -P** on a shared-memory dump file that does not have the buffer pool, the output is:

  ```
  Nobuffs dumpfile -- this information is not available
  ```

Related reference:
DUMPSHMEM configuration parameter (UNIX)
onstat -g seg command: Print shared memory segment statistics

onstat -a command: Print overall status of the database server

Use the **onstat -a** command to display information about the status of the database server. This command does not display information about all of the onstat options, only about those onstat options used for initial troubleshooting.

Syntax:

```
>>-onstat-- -a-------------------------------------------------><
```

onstat -b command: Print buffer information for buffers in use

Use the **onstat -b** option to display information about the buffers that are currently in use, including the total number of resident pages in the buffer pool.

Syntax:

```
>>-onstat-- -b-------------------------------------------------><
```

The maximum number of buffers available is specified in the **buffers** field in the BUFFERPOOL configuration parameter in the ONCONFIG file.

The **onstat -b** command also provides summary information about the number of modified buffers, the total number of resident pages in the buffer pool, the total number of buffers available, the number of hash buckets available, and the size of the buffer in bytes (the page size).

```
123 modified, 23 resident, 2000 total, 2048 hash buckets, 2048 buffer size.
```

For information about displaying information about all buffers, use onstat -B command: Prints information about used buffers.

Example output

Following is sample output from the **onstat -b** command. For a description of the output, see onstat -B command: Prints information about used buffers.

Figure 1. **onstat -b** command output

```
Buffer pool page size: 4096

address          userthread flgs pagenum memaddr          nslots pgflgs xflgs owner waitlist
70000001097e9e8 0            c07 1:47841 7000000118e0000 10     1      0     0     0
700000010982188 0            807 1:47827 700000011939000 225    90     10    0     0
2011 modified, 50000 total, 65536 hash buckets, 4096 buffer size
```

onstat -B command: Prints information about used buffers

Use the **onstat -B** option to display information about buffers that are not on the free-list.

Syntax:

```
>>-onstat-- -B-------------------------------------------------><
```

Both **onstat -B** and **onstat -b** display the similar information, except that the **onstat -b** command only displays buffers that are currently being accessed by a user thread. The **onstat -B** command displays information for all the buffers that are not on the free-list.

For information about running the **onstat -B** command on a dump file created without the buffer pool, see Running onstat Commands on a Shared Memory Dump File.

Example output

Output description

Buffer pool page size
: the size of the buffer pool pages in bytes

address
: the address of the buffer header in the buffer table

userthread
: the address of the most recent user thread to access the buffer table. Many user threads might be reading the same buffer concurrently.

flgs
: Uses the following flag bits to describe the buffer:

  0x01
  : Modified data

  0x02
  : Data

  0x04
  : LRU

  0x08
  : Error

pagenum
: the physical page number on the disk

memaddr
: the buffer memory address

nslots
: the number of slot-table entries in the page
  This field indicates the number of rows (or portions of a row) that are stored on the page.

pgflgs
Uses the following values, alone or in combination, to describe the page type:

1
Data page
2
Tblspace page
4
Free-list page
8
Chunk free-list page
9
Remainder data page
b
Partition resident blobpage
c
Blobspace resident blobpage
d
Blob chunk free-list bit page
e
Blob chunk blob map page
10
B-tree node page
20
B-tree root-node page
40
B-tree branch-node page
80
B-tree leaf-node page
100
Logical-log page
200
Last page of logical log
400
Sync page of logical log
800
Physical log
1000
Reserved root page
2000
No physical log required
8000
B-tree leaf with default flags

xflgs
Uses the following flag bits to describe buffer access:

0x10
share lock
0x80
exclusive lock

owner
the user thread that set the **xflgs** buffer flag
waitlist
the address of the first user thread that is waiting for access to this buffer
For a complete list of all threads waiting for the buffer, refer to onstat -X command: Print thread information.

onstat -c command: Print ONCONFIG file contents

Use the **onstat -c** command to display the contents of the ONCONFIG file.

```
Syntax:

>>-onstat-- -c-------------------------------------------------><
```

The database server first checks if you have assigned a value to the environment variable **ONCONFIG**. You can use the **onstat -c** option with the database server in any mode, including offline.

UNIX Only:
On UNIX, if you have set **ONCONFIG**, **onstat -c** displays the contents of the **$INFORMIXDIR/etc/$ONCONFIG** file. If not, by default, **onstat -c** displays the contents of **$INFORMIXDIR/etc/onconfig**.

Windows Only:
On Windows, if you have set **ONCONFIG**, **onstat -c** displays the contents of the **%INFORMIXDIR%\etc\%ONCONFIG%** file. If not, by default, **onstat -c** displays the contents of **%INFORMIXDIR%\etc\onconfig**.

Related tasks:
Displaying the settings in the onconfig file
Related reference:
onstat -g cfg command: Print the current values of configuration parameters
Database server files

onstat -C command: Print B-tree scanner information

Use the **-C** command to display information about the B-tree scanner subsystem and each B-tree scanner thread.

```
Syntax:

>>-onstat-- -C--+-prof--+--------------------------------------><
               +-hot---+
               +-part--+
               +-clean-+
               +-range-+
               +-map---+
               +-alice-+
               '-all---'
```

The following options are available with the **onstat -C** command and can be combined:

prof
: Prints the profile information for the system and each B-tree scanner thread. This is the default option.

hot
: Prints the hot list index key in the order to be cleaned

part
: Prints all partitions with index statistics

clean
: Prints information about all the partitions that were cleaned or need to be cleaned

range
: Prints the savings in pages processed by using index range scanning

map
: Displays the current bitmaps for each index being cleaned by the alice cleaning method

alice
: Displays the efficiency of the alice cleaning method option

all
: Prints all **onstat -C** options

Example output using the prof option

Figure 1. **onstat -C** command output with the prof option

```

Output description using the part option

Partnum
: The partition number for an index

Key
: Index Key

Positions
: Number of times index has been read

Compress
: Number of pages which have been compressed

Split
: Number of splits that have occurred

  C
  : Indicates partition is busy being cleaned

  N
  : Index partition no longer eligible for cleaning

Example output using the clean option

Figure 4. **onstat -C** command output with the clean option

```

Output Description

Partnum
: The partition number for an index

Mode
: The alice mode for the current partition

BM_Sz
: The size allocated for the bitmap

Used_Pg
: The size of the index in pages (used)

Dirty_Pg
: Number of dirty pages

I/O
: Number of pages read

Found
: Number of dirty pages found in reads

Eff
: How efficient was the bitmap

Adj
: Number of times the alice efficiency level for the partition was insufficient and was adjusted

onstat -d command: Print chunk information

Use the **onstat -d** command to show information about chunks in each storage space.

Syntax:

```
>>-onstat-- -d--+--------+---------------------------------------><
               '-update-'
```

The **update** option updates shared memory to obtain accurate counts of free pages.

Using onstat -d with sbspaces

For information about using **onstat -d** to determine the size of sbspaces, user-data areas, and metadata areas, see Monitor sbspaces.

Using onstat -d with blobspaces

If you run the **onstat -d** command on a server that has blobspace chunks, the database server displays the following message:

```
NOTE: For BLOB chunks, the number of free pages shown is out of date.
 Run 'onstat -d update' for current stats.
```

To obtain the current statistics for blobspace chunks, run the **onstat -d update** command. The **onstat** utility updates shared memory with an accurate count of free pages for each blobspace chunk. The database server shows the following message:

```
Waiting for server to update BLOB chunk statistics ...
```

Example output

Figure 1. onstat -d command output

```
BM Informix Dynamic Server Version 14.10.F       -- On-Line -- Up 00:01:27 -- 133540 Kbytes

NOTE: The values in the "size" and "free" columns for DBspace chunks are
      displayed in terms of "pgsize" of the DBspace to which they belong.

Expanded chunk capacity mode: always
```

Output description for dbspaces

The first section of the output describes the storage spaces:

address
: Is the address of the storage space in the shared-memory space table

number
: Is the unique ID number of the storage space that is assigned at when it is created

flags
: Uses hexadecimal values to describe each storage space. The individual flag values can be summed to show cumulative properties of the dbspace. The following table describes each hexadecimal value:

Table 1. Descriptions for each hexadecimal value

Flag Value	Description
0x0001	Mirror is allowed and dbspace is unmirrored.
0x0002	Mirror is allowed and dbspace is mirrored.
0x0004	The dbspace contains disabled mirror chunks.
0x0008	Newly mirrored
0x0010	Blobspace
0x0200	Space is being recovered.
0x0400	Space is physically recovered.
0x0800	Logical log is being recovered.
0x2000	Temporary dbspace
0x4000	Blobspace is being backed up.
0x8000	Sbspace
0x10000	Physical or logical log changed.
0x20000	Dbspace or chunk tables changed.
0x040000	Blobspace contains large chunks.
0x080000	Chunk in this dbspace was renamed.
0x00100000	Temporary dbspace that is used by only by shared disk secondary server. It is one of the dbspaces listed in the SDS_TEMPDBS configuration parameter on the SD secondary server.
0x00200000	Temporary dbspace for the SD secondary server. Listed in the DBSPACETEMP configuration parameter on the shared disk secondary server.
0x00400000	The dbspace was externally backed up.
0x00800000	Dbspace is being defragmented.

Flag Value	Description
0x01000000	Plogspace
0x10000000	The space is encrypted.

fchunk
: The ID number of the first chunk

nchunks
: The number of chunks in the storage space

pgsize
: The size of the dbspace pages in bytes

flags
: Uses the following letter codes to describe each storage space:

Position 1:

Flag	Description
M	Mirrored
N	Not mirrored

Position 2:

Flag	Description
X	Newly mirrored
P	Physically recovered, waiting for logical recovery
L	Being logically recovered
R	Being recovered
D	Down

Position 3:

Flag	Description
B	Blobspace
P	Plogspace
S	Sbspace
T	Temporary dbspace
U	Temporary sbspace
W	Temporary dbspace on primary server (This flag is shown on SD secondary servers only.)

Position 4:

Flag	Description
B	The dbspace can have large chunks that are greater than 2 GB.

Position 5:

Flag	Description
A	The dbspace is auto-expandable because the SP_AUTOEXPAND configuration parameter is enabled and the dbspace is configured with a create size or extend size that is not zero.

Position 6:

Flag	Description
E	The storage space is encrypted.

owner
: The owner of the storage space

name
: The name of the storage space

In the line immediately following the storage-space list, **active** refers to the current number of storage spaces in the database server instance, including the root dbspace and **maximum** refers to total allowable spaces for this database server instance.

Output description - Chunks

The second section of the **onstat -d** command output describes the chunks:

address
: The address of the chunk

chk/dbs
: The chunk number and the associated space number

offset
: The offset into the file or raw device in base page size

size
: The size of the chunk in terms of the page size of the dbspace to which it belongs.

free
: The number of unallocated pages in the chunk in units of the page size of the associated dbspace. A value of `0` indicates that all the space in the chunk is allocated to tables, but does not indicate how much space is free inside the tables. For example, suppose you create a dbspace with one chunk of 200 MB and create one table with an extent size of 200 MB. The value of the **free** field is `0`, indicating that the chunk has no free space, however, the new empty table has 200 MB of free space.
  For a blobspace, a tilde indicates an approximate number of unallocated blobpages.

For an sbspace, indicates the number of unallocated pages of user data space and total user data space.

Note: The "onstat -d" output adds footnotes for each of the down chunks that are empty, and a special foot note for the first chunk of a down space that is empty.
Example Output for onstat -d with down space (due to first chunk out of 4), where 2 of the 4 chunks are empty and can be dropped:

```
Chunks
address          chunk/dbs     offset     size       free       bpages     flags pathname
44be2268         1      1      0          150000     83059                 PO-B-- /spaces/rootchunk
45c2b028         2      2      0          512        0                     PD-BE- /spaces/dbspace2_p_1
45c2c028         3      2      0          500        *                     PD-BE- /spaces/dbspace2_p_2
45c2d028         4      2      0          500        *                     PD-BE- /spaces/dbspace2_p_3
45c2e028         5      2      0          5000       0                     PD-BE- /spaces/dbspace2_p_4
5 active, 32766 maximum

NOTE: The values in the "size" and "free" columns for DBspace chunks are
      displayed in terms of "pgsize" of the DBspace to which they belong.

*  Down chunk is empty, and may be safely dropped.
```

Example Output for onstat -d when all chunks in down space are empty and can be dropped:

```
Chunks
address          chunk/dbs     offset     size       free       bpages     flags pathname
44be2268         1      1      0          150000     83059                 PO-B-- /spaces/rootchunk
45c2b028         2      2      0          512        **                    PD-BE- /spaces/dbspace2_p_1
45c2c028         3      2      0          500        *                     PD-BE- /spaces/dbspace2_p_2
45c2d028         4      2      0          500        *                     PD-BE- /spaces/dbspace2_p_3
45c2e028         5      2      0          5000       *                     PD-BE- /spaces/dbspace2_p_4
5 active, 32766 maximum

NOTE: The values in the "size" and "free" columns for DBspace chunks are
      displayed in terms of "pgsize" of the DBspace to which they belong.

*  Down chunk is empty, and may be safely dropped.
** Down space is empty, and may be safely dropped.
```

bpages

Is the size of the chunk in blobpages
Blobpages can be larger than disk pages; therefore, the **bpages** value can be less than the **size** value.

For an sbspace, is the size of the chunk in sbpages.

flags

Provides the chunk status information as follows:
Position 1:

Flag	Description
P	Primary
M	Mirror

Position 2:

Flag	Description
N	Renamed and either Down or Inconsistent
O	Online
D	Down
X	Newly mirrored
I	Inconsistent

Position 3:

Flag	Description
-	Dbspace
B	Blobspace
S	Sbspace

Position 4:

Flag	Description
B	The dbspace can have large chunks that are greater than 2 GB.

Position 5:

Flag	Description
E	Identifies the chunk as extendable
-	Identifies the chunk as not extendable

Position 6:

Flag	Description
-	The direct I/O or concurrent I/O option is not enabled for this cooked file chunk
C	On AIX®, the concurrent I/O option is enabled for this cooked file chunk
D	The direct I/O option is enabled for this cooked file chunk

pathname

The path name of the physical device

In the line immediately following the chunk list, **active** shows the number of active chunks (including the root chunk) and **maximum** shows the total number of chunks.

For information about page reads and page writes, run the **onstat -D** command.

Related reference:
DBSPACETEMP configuration parameter
onstat -D command: Print page-read and page-write information
DIRECT_IO configuration parameter (UNIX)
MIRROR configuration parameter
modify chunk extend argument: Extend the size of a chunk (SQL administration API)
DISK_ENCRYPTION configuration parameter

onstat -D command: Print page-read and page-write information

Use the **onstat -D** command to display page-read and page-write information for the first 50 chunks in each space.

Syntax:

```
>>-onstat-- -D-----------------------------------------------><
```

Example output

Figure 1. **onstat -D** command output

```
Dbspaces

a40d7d8  1        0x1        1        1       2048    N        informix rootdbs
 1 active, 2047 maximum

Chunks
address  chunk/dbs  offset     page Rd  page Wr  pathname
a40d928  1      1   0          0        0        /work/11.1/dbspaces/stardbs3
 1 active, 2047 maximum

Expanded chunk capacity mode: disabled
```

Output description

The output of **onstat -D** is almost identical to the output of **onstat -d**. The following columns are unique to **onstat -D**. For information on the other output columns see onstat -d command: Print chunk information.

page Rd
Is the number of pages read

page Wr
Is the number of pages written

Related reference:
onstat -d command: Print chunk information

onstat -f command: Print dbspace information affected by dataskip

Use the **-f** command to list the dbspaces that the dataskip feature currently affects.

Syntax:

```
>>-onstat-- -f-----------------------------------------------><
```

The **-f** option lists both the dbspaces that were set with the DATASKIP configuration parameter and the **-f** option of **onspaces**. When you execute **onstat -f**, the database server displays one of the following three outputs:

- Dataskip is OFF for all dbspaces.
- Dataskip is ON for all dbspaces.
- Dataskip is ON for the following dbspaces:

  ```
  dbspace1 dbspace2...
  ```

Related reference:
DATASKIP Configuration Parameter

onstat -F command: Print counts

Use the **onstat -F** command to display a count for each type of write that flushes pages to disk.

Syntax:

```
>>-onstat-- -F-------------------------------------------------><
```

Example output

Figure 1. **onstat -F** command output

```
Fg Writes     LRU Writes    Chunk Writes
0             330           7631

address  flusher  state  data  # LRU  Chunk  Wakeups  Idle Time
c7c8850  0        I      0     9      29     16116    16093.557
      states: Exit Idle Chunk Lru
```

Output description

You can interpret output from this option as follows:

Fg Writes
: Is the number of times that a foreground write occurred

LRU *Writes*
: Is the number of times that an LRU write occurred

Chunk Writes
: Is the number of times that a chunk write occurred

address
: Is the address of the user structure assigned to this page-cleaner thread

flusher
: Is the page-cleaner number

state
: Uses the following codes to indicate the current page-cleaner activity:

  C
  : Chunk write

  E
  : Exit

  I
  : Cleaner is idle

  L
  : LRU queue

  The exit code indicates either that the database server is performing a shutdown or that a page cleaner did not return from its write in a specific amount of time. When an operation fails to complete within the allotted time, this situation is known as a time-out condition. The database server does not know what happened to the cleaner, so it is marked as `exit`. In either case, the cleaner thread eventually exits.

data
: Provides additional information in concert with the **state** field
  If **state** is `C`, **data** is the chunk number to which the page cleaner is writing buffers. If **state** is `L`, **data** is the LRU queue from which the page cleaner is writing. The **data** value is displayed as a decimal, followed by an equal sign, and repeated as a hexadecimal.

#LRU
: Corresponds to the **onstat -g ath** thread ID output

Chunk
: Number of chunks cleaned

Wakeups
: Number of times the flusher thread was awoken

Idle Time
: Time in seconds the flusher thread has been idle

CLEANERS configuration parameter

onstat -g monitoring options

The options that you can use with **onstat -g** command are used for support and debugging only. You can include only one of these options in the **onstat -g** command.

The **onstat -g imc** command prints information about Informix® MaxConnect instances that are connected to the database server. If Informix MaxConnect is not connected to the database server, this command displays No MaxConnect servers are connected.

The **onstat -g nta** command prints combined network statistics from the **-g ntd**, **-g ntm**, **-g ntt**, and **-g ntu** commands. If Informix MaxConnect is installed, this command prints statistics that you can use to tune Informix MaxConnect performance.

- onstat -g act command: Print active threads
  Use the **onstat -g act** command to display information about the active threads.
- onstat -g afr command: Print allocated memory fragments
  Use the **onstat -g afr** command to display information about the allocated memory fragments for a specified session or shared-memory pool. Each session is allocated a pool of shared memory.
- onstat -g all command: Print diagnostic information
  Use the **onstat -g all** command to gather diagnostic information if advised to do so by Support. For normal administrative purposes, use the **onstat -g** command with individual options.
- onstat -g aqt command: Print data mart and accelerated query table information
  Use the **onstat -g aqt** command to display information about the data marts and the associated accelerated query tables (AQTs).
- onstat -g arc command: Print archive status
  Use the **onstat -g arc** command to display information about the last committed archive for each dbspace and also information about any current ongoing archives.
- onstat -g ath command: Print information about all threads
  Use the **onstat -g ath** command to display information about all threads.
- onstat -g bth and -g BTH: Print blocked and waiting threads
  Use the **onstat -g bth** command to display the dependencies between blocking and waiting threads. Use the **onstat -g BTH** command to display session and stack information for the blocking threads.
- onstat -g buf command: Print buffer pool profile information
  Use the **onstat -g buf** command to show profile information for each buffer pool.
- onstat -g cac command: Print information about caches
  Use the **onstat -g cac** command to see summary and detailed information about all caches or about a single cache.
- onstat -g ckp command: Print checkpoint history and configuration recommendations
  Use the **onstat -g ckp** command to print checkpoint history and show configuration recommendations if a suboptimal configuration is detected.
- onstat -g cfg command: Print the current values of configuration parameters
  Use the **onstat -g cfg** command to print a list of configuration parameters with their current values. You can use more command options to print more information about the configuration parameters.
- onstat -g cluster command: Print high-availability cluster information
  Use the **onstat -g cluster** command to display information about the servers in a high-availability cluster environment.
- onstat -g cmsm command: Print Connection Manager information
  Use the **onstat -g cmsm** command to display information about a specific Connection Manager, or all of the Connection Managers that are attached to the database server the command is run on.
- onstat -g con command: Print condition and thread information
  Use the **onstat -g con** command to display information about conditions and the threads that are waiting for the conditions.
- onstat -g cpu: Print runtime statistics
  Use the **onstat -g cpu** command to display information about runtime statistics for each thread that is running in the server.
- onstat -g dbc command: Print dbScheduler and dbWorker thread statistics
  Use the **onstat -g dbc** command to display statistics about the Scheduler tasks that are currently running, which are handled by dbWorker threads, or scheduled to be run, which are handled by the dbScheduler thread.
- onstat -g defragment command: Print defragment partition extents
  Use the **onstat -g defragment** command to display information about the active requests to defragment partition extents.
- onstat -g dic command: Print table information
  Use the **onstat -g dic** command to display a line of information about each table that is cached in the shared-memory dictionary. If you specify a table name, this command prints internal SQL information about that particular table.
- onstat -g dis command: Print database server information
  Use the **onstat -g dis** command to display a list of database servers, the status of each server, and information about each server, including the location of the **INFORMIXDIR** directory, **sqlhosts** file, and ONCONFIG file. You can use this command in any database server mode, including offline.
- onstat -g dll command: Print dynamic link library file list
  Use the **onstat -g dll** command to display a list of and the status of dynamic link library (DLL) files that were loaded.
- onstat -g dmp command: Print raw memory
  Use the **onstat -g dmp** command to display information about raw memory at a given address for a number of given bytes.
- onstat -g dri command: Print high-availability data replication information
  Use the **onstat -g dri** command, either alone or with the **ckpt** or **que** options, to print information about high-availability data replication statistics on the current server.
- onstat -g dsc command: Print distribution cache information
  Use the **onstat -g dsc** command to display information about the distribution cache.
- onstat -g dsk command: Print the progress of the currently running compression operation
  Use the **onstat -g dsk** command to print information that shows the progress of currently running compression operations, such as compress, repack, and shrink.
- onstat -g env command: Print environment variable values
  Use the **onstat -g env** command to display the values of the environment variables that the database server currently uses.
- onstat -g ffr command: Print free fragments
  Use the **onstat -g ffr** command to display information about the free memory fragments for a specified session or shared-memory pool.
- onstat -g glo command: Print global multithreading information
  Use the **onstat -g glo** command to display global information about multithreading, information about each virtual processor that is running, and cumulative statistics for each virtual-processor class. This information includes CPU use information about the virtual processors, the total number of sessions, and other multithreading global counters.
- onstat -g his command: Print SQL trace information
  Use the **onstat -g his** command to display SQL trace information from the collection of **syssqltrace** tables (syssqltrace, syssqltrace_info, syssqltrace_hvar and syssqltrace_itr) in the **sysmaster** database.
- onstat -g ioa command: Print combined onstat -g information
  Use the **onstat -g ioa** command to display combined information from the **onstat -g iob**, **onstat -g iof**, **onstat -g ioq**, and **onstat -g iov** commands.
- onstat -g iob command: Print big buffer use summary
  Use the **onstat -g iob** command to display a summary of big buffer use.
- onstat -g iof command: Print asynchronous I/O statistics
  Use the **onstat -g iof** command to display the asynchronous I/O statistics by chunk or file.
- onstat -g iog command: Print AIO global information
  Use the **onstat -g iog** command to display global information about AIO.

- onstat -g ioq command: Print I/O queue information
  Use the **onstat -g ioq** command to display statistics about the number and types of operations performed by I/O queues.
- onstat -g ipl command: Print index page logging status information
  Use the **onstat -g ipl** command to display information about the status of index page logging.
- onstat -g iov command: Print AIO VP statistics
  Use the **onstat -g iov** command to display asynchronous I/O statistics for each virtual processor.
- onstat -g lap command: Print light appends status information
  Use the **onstat -g lap** command to display information about the status of light appends occurring in the system.
- onstat -g laq command: Print log apply queues
  Use the **onstat -g laq** command to print information about log recovery apply queues.
- onstat -g lmm command: Print low memory management information
  Use the **onstat -g lmm** command to display information about automatic low memory management settings and recent activity.
- onstat -g lmx command: Print all locked mutexes
  Use the **onstat -g lmx** command to display information about all locked mutexes.
- onstat -g lsc command: Print active light scan status (deprecated)
  The **onstat -g lsc** command has been superseded by the **onstat -g scn** command.
- onstat -g mem command: Print pool memory statistics
  Use the **onstat -g mem** command to display the memory statistics for a pool.
- onstat -g mgm command: Print MGM resource information
  Use the **onstat -g mgm** command to show resource information about Memory Grant Manager (MGM).
- onstat -g nbm command: Print a block bit map
  Use the **onstat -g nbm** command to display the block bit map for the nonresident segments.
- onstat -g nsc command: Print current shared memory connection information
  Use the **onstat -g nsc** command to display information about shared memory connections either for all of the current connections or for a specified connection ID.
- onstat -g nsd command: Print poll threads shared-memory data
  Use the **onstat -g nsd** command to display information about shared-memory data for poll threads.
- onstat -g nss command: Print shared memory network connections status
  Use the **onstat -g nss** *sessionid* command to display information about the status of the shared memory network connections.
- onstat -g ntd command: Print network statistics
  Use the **onstat -g ntd** command to display network statistics by service.
- onstat -g ntm command: Print network mail statistics
  Use the **onstat -g ntm** command to display statistics about network mail.
- onstat -g ntt command: Print network user times
  Use the **onstat -g ntt** command to display information about network user times.
- onstat -g ntu command: Print network user statistics
  Use the **onstat -g ntu** command to display information about network user statistics.
- onstat -g opn command: Print open partitions
  Use the **onstat -g opn** command to display a list of the partitions (tables and indexes), by thread ID, that are currently open in the system.
- onstat -g osi: Print operating system information
  Use the **onstat -g osi** command to display information on your operating system resources and parameters, including shared memory and semaphore parameters, the amount of memory currently configured on the computer, and the amount of memory that is unused.
- onstat -g pd command: Print push data session-related information
  Use the **onstat -g pd** command to display information about the push data session.
- onstat -g pd event command: Print push data event-related information
  Use the **onstat -g pd** event command to display information about the push data event.
- onstat -g pfsc command: Print partition free space cache information
  Use the **onstat -g pfsc** command to display information about all partition free space caches.
- onstat -g pos command: Print file values
  Use the **onstat -g pos** command to display the values in the **$INFORMIXDIR/etc/.infos.DBSERVERNAME** file.
- onstat -g ppd command: Print partition compression dictionary information
  Use the **onstat –g ppd** command to display information about the active compression dictionaries that were created for compressed tables and table fragments or compressed B-tree indexes. You can choose to print information for a particular numbered partition or for all open partitions.
- onstat -g ppf command: Print partition profiles
  Use the **onstat -g ppf *partition_number*** command to display the partition profile for the specified partition number.
- onstat -g pqs command: Print operators for all SQL queries
  Use the **onstat –g pqs** command to display information about the operators used in all of the SQL queries that are currently running.
- onstat -g prc command: Print sessions using UDR or SPL routines
  Use the **onstat -g prc** command to display the number of sessions that are currently using the UDR or SPL routine.
- onstat -g proxy command: Print proxy distributor information
  Use the **onstat -g proxy** command to display information about proxy distributors. The output of the **onstat -g proxy** command differs slightly depending on whether the command is run on a primary server or on a secondary server.
- onstat -g qst command: Print wait options for mutex and condition queues
  Use the **onstat -g qst** command to display the wait statistics for mutex queues and condition queues (queues of waiters for a mutex or a condition).
- onstat -g rah command: Print read-ahead request statistics
  Use the **onstat -g rah** command to display information about read-ahead requests.
- onstat -g rbm command: Print a block map of shared memory
  Use the **onstat -g rbm** command to display a hexadecimal bitmap of the free and used blocks within the resident segment of shared memory.
- onstat -g rea command: Print ready threads
  Use the **onstat -g rea** command to display information about the virtual processor threads whose current status is ready.
- onstat -g rss command: Print RS secondary server information
  Use the **onstat -g rss** commands to display information about remote standalone secondary servers.
- onstat -g rwm command: Print read and write mutexes
  Use the **onstat -g rwm** command to display information about read, write, and waiting mutex threads, and to list the addresses of the tickets that these threads have acquired.
- onstat -g sch command: Print VP information
  Use the **onstat -g sch** command to display information about thread migration and the number of semaphore operations, spins, and busy waits for each virtual processor.
- onstat -g scn command: Print scan information
  Use the **onstat -g scn** command to display the status of a current scan and information about the scan.

- onstat -g sds command: Print SD secondary server information
  Use the **onstat -g sds** command to display information about shared-disk secondary servers.
- onstat -g seg command: Print shared memory segment statistics
  Use the **onstat -g seg** command to show the statistics for shared memory segments.
- onstat -g ses command: Print session-related information
  Use the **onstat -g ses** command to display information about the session.
- onstat -g shard command: Print information about the shard definition
  Use the **onstat -g shard** command to display information about the sharding definition.
- onstat -g sle command: Print all sleeping threads
  Use the **onstat -g sle** command to print all sleeping threads.
- onstat -g smb command: Print sbspaces information
  Use the **onstat -g smb** command to display detailed information about sbspaces.
- onstat -g smx command: Print multiplexer group information
  Use the **onstat -g smx** command to display information about the server multiplexer group for servers using SMX.
- onstat -g spi command: Print spin locks with long spins
  Use the **onstat -g spi** command to display information about spin locks with long spins.
- onstat -g sql command: Print SQL-related session information
  Use the **onstat -g sql** command to display SQL-related information about a session.
- onstat -g spf: Print prepared statement profiles
  Use the **onstat -g spf** command to display current statistics about SQL queries.
- onstat -g src command: Patterns in shared memory
  Use the **onstat -g src** command to search for patterns in shared memory.
- onstat -g ssc command: Print SQL statement occurrences
  Use the **onstat -g ssc** command to monitor the number of times that the database server reads the SQL statement in the cache.
- onstat -g stk command: Print thread stack
  Use the **onstat -g stk** *tid* command to display the stack of the thread specified by thread ID.
- onstat -g stm command: Print SQL statement memory usage
  Use the **onstat -g stm** command to display the memory that each prepared SQL statement uses.
- onstat -g stq command: Print queue information
  Use the **onstat -g stq** command to display information about the queue.
- onstat -g sts command: Print stack usage for each thread
  Use the **onstat -g sts** command to display information about the maximum and current stack use for each thread.
- onstat -g sym command: Print symbol table information for the oninit utility
  Use the **onstat -g sym** command to display symbol table information for the **oninit** utility.
- onstat -g top command: Print top consumers of resources
  Use the **onstat -g top** command to display information about top consumers of various resources such as CPU time, I/O operations, and memory growth.
- onstat -g tpf command: Print thread profiles
  Use the **onstat -g tpf** command to display thread profiles.
- onstat -g ufr command: Print memory pool fragments
  Use the **onstat -g ufr** command to display a list of the fragments that are currently in use in the specified memory pool.
- onstat -g vpcache command: Print CPU virtual processor and tenant virtual processor private memory cache statistics
  Run the **onstat -g vpcache** command to display statistics about CPU virtual processor and tenant virtual processor private memory caches.
- onstat -g wai command: Print wait queue thread list
  Use the **onstat -g wai** command to display a list of the threads in the system that are currently in the wait queue and not currently executing. The output is sorted by thread ID.
- onstat -g wmx command: Print all mutexes with waiters
  Use the **onstat -g wmx** command to display all of the mutexes with waiters.
- onstat -g wst command: Print wait statistics for threads
  Use the **onstat -g wst** command to show the wait statistics for the threads within the system.

Related information:
onstat -g commands for Enterprise Replication

onstat -g act command: Print active threads

Use the **onstat -g act** command to display information about the active threads.

Syntax:

```
>>-onstat-- -g--act-----------------------------------------><
```

Following is sample output from the **onstat -g act** command. For a description of the output, see onstat -g ath command: Print information about all threads.

Example output

Figure 1. **onstat -g act** command output

```
Running threads:
tid  tcb         rstcb  prty  status    vp-class     name
2    b3132d8     0      1     running   *2adm        adminthd
40   c5384d0     0      1     running   *1cpu        tlitcppoll
```

onstat -g afr command: Print allocated memory fragments

Use the **onstat -g afr** command to display information about the allocated memory fragments for a specified session or shared-memory pool. Each session is allocated a pool of shared memory.

Syntax:

```
>>-onstat-- -g--afr--+-pool_name----+-------------------------><
                     +-sessionid----+
                     '-pool_address-'
```

This command requires an additional argument to specify either a pool name, a session ID, or a pool address. Each session is allocated a memory pool with the same name as the session ID.

The *pool_name* is the name of the shared-memory pool. Run the **onstat -g mem** command to identify the pool name.

The *sessionid* is the session ID. Run the **onstat -g ses** command to identify the session ID.

The *pool_address* is the address of the shared-memory pool. Run the **onstat -g mem** command or the **onstat -g ses** command to identify the pool address.

Example output

Figure 1. **onstat -g afr** command output

```
Allocations for pool name global:
addr             size       memid          fileid   location
4b231000         3288       overhead       306      mtshpool.c:617

4b231e40         64         osenv          2909     osenv.c:1164
4b231e80         64         osenv          2909     osenv.c:1971
```

Output description

addr (hexadecimal)
: Memory address of the pool fragment.

size (decimal)
: Size, in bytes, of the pool fragment.

memid (string)
: Memory ID of the pool fragment.

fileid (decimal)
: Internal use only. Code file identifier for the allocation.

location (string)
: Internal use only. Line number in the code for the allocation.

onstat -g all command: Print diagnostic information

Use the **onstat -g all** command to gather diagnostic information if advised to do so by Support. For normal administrative purposes, use the **onstat -g** command with individual options.

Syntax:

```
>>-onstat-- -g--all-------------------------------------------><
```

onstat -g aqt command: Print data mart and accelerated query table information

Use the **onstat -g aqt** command to display information about the data marts and the associated accelerated query tables (AQTs).

Syntax:

```
>>-onstat-- -g--aqt--+----------+------------------------------><
                    '-aqt_name-'
```

Example output

Figure 1. **onstat -g aqt** command output

```

Output description

The AQTs are grouped by the data mart that they belong to. The groups are sorted by accelerator name, and then by data mart name. Within the data mart groups, the AQTs are sorted in the following order: Fact table tabid (`FactTab`), number of tables (`#tab`), and AQT name.

The output comes from the entries in the dictionary cache that refer to the AQTs of the data marts. The output is shown only if the AQTs have been loaded into the dictionary cache, which normally occurs when a query is being matched against the AQTs.

Before the server attempts to match a query against the AQTs, the AQTs do not have any entries in the dictionary cache. The **onstat -g aqt** command will not show any entries in the output. When the dictionary cache is initialized during the database server startup, the columns `#matched` and `address` get new values.

The **onstat -g aqt** command prints the following information:

mart
: The name of the data mart

accelerator
: The name of the accelerator instance

last load
: The time stamp for when the data mart was last loaded

AQT name
: The unique system-generated name of the AQT

FactTab
: The tabid of the fact table for the AQT

#tab
: The number of tables that are part of the AQT

#matched
: The counter for query matches that have occurred for the AQT

address
: The internal database server memory address for the AQT

The **onstat -g aqt *aqt_name*** command prints the following information:

AQT
: The unique system-generated name of the AQT

database
: The name of the database to which the AQT belongs

AQT tabid
: The tabid for the entry that constitutes the AQT in the `systables` system catalog table of the database server.

Fact table
: The tabid of the fact table of the AQT

Number of times matched
: The counter for query matches that have occurred for the AQT

The information about the AQT is followed by a textual representation of the star schema of the data mart. The textual representation shows how the columns of the tables are related to each other in the star join.

For information about the Informix® Warehouse Accelerator, see the *IBM® Informix Warehouse Accelerator Administration Guide*.

---

onstat -g arc command: Print archive status

Use the **onstat -g arc** command to display information about the last committed archive for each dbspace and also information about any current ongoing archives.

Syntax:

```
>>-onstat-- -g--arc-----------------------------------------><
```

Example output

Figure 1. **onstat -g arc** command output

```
Dbspaces - Ongoing archives
number   name            Q Size Q Len  buffer partnum    size     Current-page

```

Output description - Ongoing archives

This output section represents current information about the archives. If no archives are active in the system, this section is not displayed.

Column	Description
Number	The number of the dbspace
Name	The name of the dbspace
Q Size	The before-image queue list size. This information is primarily for support.
Q Len	The before-image queue length. This information is primarily for support.
Buffer	The number of pages used in the before-image buffer
Partnum	The partition number of the before-image bin
Size	The number of pages in the before-image bin

Current-page	The current page that is being archived

Note: The before-image bin is a temporary table created in a temporary dbspace, or in the root dbspace if you do not have any temporary dbspaces. If the before-image bin becomes too small, it can extend to additional partitions, in which case the output will display see multiple Partnum and Size fields for the same dbspace.

Output description - Archive status

This output section contains information about the last backup that has occurred for each dbspace.

Column	Description
Name	The name of the dbspace
Number	The dbspace number
Level	The archive level
Date	The date and time of the last archive
Log	The unique ID (UNIQID) of the checkpoint that was used to start the archive
Log-position	The log position (LOGPOS) of the checkpoint that was used to start the archive

onstat -g ath command: Print information about all threads

Use the **onstat -g ath** command to display information about all threads.

Syntax:

```
>>-onstat-- -g--ath-------------------------------------------><
```

Example output

Figure 1. onstat -g ath command output

```

: Session ID

The session information section contains the same information that is output from the **onstat -g ses** command. See onstat -g ses command: Print session-related information.

The remainder of the information displays the stack information for the thread.

Related information:
Monitor blocking threads with the onstat -g bth and onstat -g BTH commands

onstat -g buf command: Print buffer pool profile information

Use the **onstat -g buf** command to show profile information for each buffer pool.

Syntax:

```
>>-onstat-- -g--buf-------------------------------------------><
```

Example output

The output of the **onstat -g buf** command varies slightly depending on whether the BUFFERPOOL configuration parameter setting contains the **memory** field or the **buffers** field. The output for the **memory** setting is shown. The output for the **buffers** setting contains the **max extends** and **next buffers** fields instead of the **max memory** and **next memory** fields.

Figure 1. onstat -g buf output for the memory setting

```

Output description

Buffer pool page size
: The number of bytes in a page in the buffer pool

dskreads
: The number of disk read operations that are performed to bring pages into this buffer pool. Each read operation reads one or more pages.

pagreads
: The number of pages that are read from disk to this buffer pool.

bufreads
: The number of times a memory image for a page was read from this buffer pool.

%cached
: The percentage of page reads for this buffer pool that were satisfied by a cached page image (rather than having to perform a disk read). Computed as `(bufreads - dskreads) / bufreads x 100`. Higher percentages indicate better caching performance.

dskwrits
: The number of disk write operations that are performed to write changed pages from this buffer pool back to disk. Each write operation writes one or more pages.

pagwrits
: The number of pages that are written to disk from this buffer pool.

bufwrits
: The number of times a memory image of a page was written to in this buffer pool.

%cached
: The percentage of page writes for this buffer pool that were satisfied by a cached page image (rather than having to perform a disk write). Computed as `(bufwrits - dskwrits) / bufwrits x 100`.

bufwrits_sinceckpt
: The number of times a memory image of a page was written to in this buffer pool since the last checkpoint.

bufwaits
: The number of times a thread had to wait for a lock on a buffer in this buffer pool. Higher numbers indicate more contention among multiple threads for mutually incompatible locks on the same pages.

ovbuff
: The number of times a changed buffer from this buffer pool was written to disk specifically to create a free buffer to read another requested page. If the `ovbuff` value is high, the buffer pool might not be large enough to hold the working set of pages that are needed by applications. An insufficient buffer pool can lead to performance degradation.

flushes
: The number of times the server flushed all dirty buffers at once in the buffer pool. Mass flushing can occur for various reasons, including as part of checkpoint processing or if the buffer pool is running out of clean buffers despite normal LRU cleaning activity.

Fg Writes
: Number of changed buffers from this buffer pool that were written to disk by a non-I/O flusher thread that was accessing the buffer. This number is a superset of the value of the `ovbuff` field. In addition to the writes to service page faults that are counted in the `ovbuff` field, this value also includes foreground writes to

maintain the consistency of database logs and reserved pages to ensure a correct recovery.

LRU Writes
: The number of changed buffers from this buffer pool that were written to disk by an LRU cleaner thread. LRU cleaners are activated if the buffer pool exceeds the value that is specified in the **lru_max_dirty** field of the BUFFERPOOL configuration parameter or if foreground writes occur due to buffer pool overflows.

Avg. LRU Time
: The average amount of time that is taken by an LRU cleaner thread to clean a single LRU chain.

Chunk Writes
: The number of changed buffers that were written to disk by a chunk cleaning operation. Chunk cleaning writes out all changed buffers of a chunk that are in the buffer pool. Chunk cleaning is done to clean many buffers quickly, such as during checkpoint processing and fast recovery.

Total Mem
: The size of the buffer pool.

extends
: The number of times that the buffer pool was extended.

max memory (memory setting)
: The target maximum size of the buffer pool. The actual size of the buffer pool can exceed this value, but not more than the size of one segment.

max extends (buffers setting)
: The maximum number of times that the buffer pool can be extended. (This field is not shown in the example output.)

next memory (memory setting)
: The size of the next extension of the buffer pool.

next buffers (buffers setting)
: The number of buffers for the next extension of the buffer pool. (This field is not shown in the example output.)

cache hit ratio
: The read cache hit ratio below which the buffer pool is extended.

last
: The time of the last extension of the buffer pool.

id
: The ID of the buffer pool segment.

segment
: The internal address of the buffer pool segment.

size
: The size of the buffer pool segment.

buffs
: The number of buffers in the buffer pool segment.

Fast Cache Stats
: Statistics for the fast cache, which is a type of cache that reduces the time that is needed for accessing the buffer pool.

gets
: The number of times the server looked for a buffer in the fast cache.

hits
: The number of times that the server found the buffer it was searching for in the fast cache.

%hits
: The percentage of hits, which is `hits*100/gets`.

puts
: The number of times that the server inserted buffers inserted into the fast cache.

onstat -g cac command: Print information about caches

Use the **onstat -g cac** command to see summary and detailed information about all caches or about a single cache.

Syntax:

Use the **onstat -g cac** command without any options to see information about all caches.

Use the following options to see information about a specific cache:

agg
: Prints information about the aggregate cache.

aqt
: Prints information about the AQT dictionary cache. Prints the same output as the **onstat -g aqt** command. See onstat -g aqt command: Print data mart and accelerated query table information.

am
: Prints information about the access method cache. To see information for a specific access method, include the access method name.

cast
: Prints information about the cast cache.

dic
: Prints information about the data dictionary cache. Prints the same output as the **onstat -g dic** command. See onstat -g dic command: Print table information.

dsc
: Prints information about the data distribution cache. Prints the same output as the **onstat -g dsc** command. See onstat -g dsc command: Print distribution cache information.

ed
: Prints information about the external directives cache.

lbacplcy
: Prints information about the LBAC security policy information cache.

lbacusrc
: Prints information about the LBAC credential memory cache.

opci
: Prints information about the operator class instance cache.

prc
: Prints information about the UDR cache. Prints the same output as the **onstat -g prc** command. See onstat -g prc command: Print sessions using UDR or SPL routines.

prn
: Prints information about the procedure name cache.

rr
: Prints information about the routine resolution cache.

ssc
: Prints information about the SQL statement cache. Prints the same output as the **onstat -g ssc** command. See onstat -g ssc command: Print SQL statement occurrences.

ttype
: Prints information about the secondary transient cache.

typei
: Prints information about the extended type by ID cache. To see information for a specific extended type, include the extended type ID.

typen
: Prints information about the extended type by name cache. To see information for a specific extended type, include the extended type name.

Example output

The output of most **onstat -g cac** commands contains similar format and information.

The following output is an example of the **onstat -g cac lbacplcy** command:

```
Security Policy Info Cache Entries:

list id   ref  drop hits       last_access          heap_ptr         item
--------------------------------------------------------------------------------

9    2    0    0    0          2020-05-12 10:36:34  65f1b8d0         test@informix: : secpolicyid 2

15   1    0    0    0          2020-05-12 10:36:34  65f1b4d0         test@informix: : secpolicyid 1

    Total number of entries  : 2
    Number of entries in use : 0
```

Output description

The output of most **onstat -g cac** commands contains the following fields:

Number of lists
: Number of lists in the distribution cache

configuration parameter name
: Number of entries that can be cached at one time

list
: Distribution cache hash chain ID

id
: The unique ID assigned to the cache entry

ref
: Number of statements that reference a cache entry

drop
: Whether this entry was dropped after it was added to the cache

hits
: The number of times the cache entry is accessed

last_access
: The time at which the cache entry was last accessed.

heap_ptr
: Heap address that is used to store this entry

item name
: The name of the item in the cache

Total number of entries
: Number of entries in the cache

Number of entries in use
: Number of entries that are being used

Output description

Auto Checkpoints
: Indicates if the AUTO_CKPTS configuration parameter is on or off

RTO_SERVER_RESTART
: Displays the RTO time in seconds. Zero (0) means that RTO is off.

Estimated recovery time ## seconds
: Indicates the estimated recovery time if the data server stops responding. This value appears only if RTO_SERVER_RESTART is active.

Interval
: Checkpoint interval ID

Clock Time
: Clock time when checkpoint occurred.

Trigger
: Event that triggered the checkpoint. An asterisk (*) indicates that the checkpoint that was requested was a transaction-blocking checkpoint.

Trigger name	Description
Admin	Administrator-related tasks. For example: • Create, drop, or rename a dbspace • Add or drop a chunk • Add or drop a log file • Change physical log size or location • After "shrink" operation on partition • Turn on or off mirroring
Backup	Back up related operations. For example:

	• Fake backup • Start of an archive • After the completion of a physical restore
CDR	ER subsystem is started for the first time, or is restarted after all of the replication participants were removed.
CKPTINTVL	When the checkpoint interval expires. The checkpoint interval is the value that is specified for the CKPTINTVL parameter in the onconfig file.
Conv/Rev	Conversion reversion checkpoint. After the check phase of convert and before the actual conversion of disk structures. After the reversion is completed also triggers a checkpoint.
HA	High availability. For example: • A new RSS or SDS node is added to a High Availability cluster • A secondary server is promoted to a primary server • The physical log file is low on a secondary server
HDR	High-Availability Data Replication. For example: • The mode of the server is changed • The start of the first transfer after HDR is set up • There is the potential for a physical log overflow on primary or secondary servers
IPL	Trigger checkpoint to reduce physical log usage on the secondary server. Index page logging can cause foreground writes and heavy physical log usage on secondary servers.
Lightscan	Before the look aside is turned off on partitions.
Llog	Running out of logical log resources.
LongTX	Long Transaction. If a long transaction was found but not stopped, a checkpoint is initiated to stop the transaction. During rollback, a checkpoint is initiated in the rollback phase if a checkpoint has not already happened after long transaction was aborted.
Misc	Miscellaneous events. For example: • A dbspace or chunk is being brought down because of I/O errors • During rollback when the addition of the chunk is being undone: for example, when removing the chunk.
Pload	When the High-Performance Loader starts in the Express mode.
Plog	Physical log has one of the following conditions: • Physical log is 75% full • The amount of physical log used plus the number of dirty partitions is more than 90% of physical log size
Restore Pt	Restore Point. Checkpoints at the start and end of a restore point. The restore point is (used by conversion guard) CONVERSION_GUARD configuration parameter is enabled and a temporary directory is specified in the RESTORE_POINT_DIR configuration parameter.
Recovery	During a restore, at the start of a fast recovery.
Reorg	At the start of online index build.
RTO	Maintaining the Recovery Time Objective (RTO) policy. During normal operations, when the restart time after a crash might exceed the value that is set for the RTO_SERVER_RESTART configuration parameter.
Stamp Wrap	Checkpoint timestamp. If the new checkpoint timestamp appears to be before the last written checkpoint, then the timestamp is advanced out of interval between checkpoints. Another checkpoint is triggered.
Startup	At the startup of the database server.
Uncompress	Uncompress commands that are issued on a table or partition. This applies only for checkpoints on tables or databases that are not logged.
User	A checkpoint request is submitted by the user.

LSN
: Logical log position where checkpoint is recorded

Total Time
: Total checkpoint duration, in seconds, from request time to checkpoint completion

Flush Time
: Time, in seconds, to flush buffer pools

Block Time
: Time a transaction was blocked, in seconds, by a checkpoint that was triggered by a scarcity of some needed resource. For example, running out of physical log, or wrap-around of the logical log.

Waits
: Number of transactions that are blocked waiting for checkpoint

Ckpt Time
: Time, in seconds, for all transactions to recognize a requested checkpoint

Wait Time
: Average time, in seconds, that transactions waited for checkpoint

Long Time
: Longest amount of time, in seconds, a transaction waited for checkpoint

Dirty Buffers
: Number of dirty buffers that are flushed to disk during checkpoint

Dskflu/sec
: Number of buffers that are flushed per second

Physical Log Total Pages
: Total number of pages that are physically logged during checkpoint interval

Physical Log Avg/Sec
: Average rate of physical log activity during checkpoint interval

Logical Log Total Pages
: Total number of pages that are logically logged during checkpoint interval

Logical Log Avg/Sec
: Average rate of logical log activity during checkpoint interval

Max Plog pages/sec
: Maximum rate of physical log activity during checkpoint interval

Max Llog pages/sec
: Maximum rate of logical log activity during checkpoint interval

Max Dskflush Time
: Maximum time, in seconds, to flush buffer pools to disk

Avg Dskflush pages/sec
: Average rate buffer pools are flushed to disk

Avg Dirty pages/sec
: Average rate of dirty pages between checkpoints

Blocked Time
: Longest blocked time, in seconds, since the database server was last started

Performance advisory messages

If the data server detects a configuration that is less than optimal, a performance advisory message with tuning recommendations appears below the checkpoint history. This performance advisory message also appears in the message log. Following are examples of performance advisory messages:

```
Physical log is too small for bufferpool size. System performance may be
less than optimal.
Increase physical log size to at least %ldKb

Physical log is too small for optimal performance.
Increase the physical log size to at least $ldKb.

Logical log space is too small for optimal performance.
Increase the total size of the logial log space to at least %ld Kb.

Transaction blocking has taken place. The physical log is too small.
Please increase the size of the physical log to %ldKb

Transaction blocking has taken place. The logical log space is too small.
Please increase the size of the logical log space to %ldKb
```

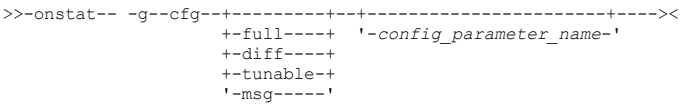
onstat -g cfg command: Print the current values of configuration parameters

Use the **onstat -g cfg** command to print a list of configuration parameters with their current values. You can use more command options to print more information about the configuration parameters.

Syntax:



This **onstat -g cfg** command has the following formats:

Command	Description
onstat -g cfg	Displays a list of configuration parameters and their current values.
onstat -g cfg *config_parameter_name*	Displays only the current value of the specified configuration parameter.
onstat -g cfg full	Displays all of the information about each configuration parameter, including the current value, the default value, the onconfig file value, and a description of the parameter.
onstat -g cfg full *config_parameter_name*	Displays all of the information about the specified parameter.
onstat -g cfg diff	Displays information about the configuration parameters with current values that are different from the permanent values that are in the onconfig file.
onstat -g cfg tunable	Displays the default, original, and current values for all tunable parameters. An asterisk indicates that you can tune a configuration parameter dynamically.
onstat -g cfg msg	Displays any messages, such as warnings or adjustments, that are associated with configuration parameters.

Example output

The following portion of sample output of the **onstat -g cfg** command shows that the value of the DEADLOCK_TIMEOUT configuration parameter was dynamically changed to 90 seconds after the database server started:

```
id   name                 type   units   rsvd  tunable
26   DEADLOCK_TIMEOUT     INT4   Seconds       *

     min/max : 0,2147483647
     default : 60
     onconfig:
     current : 90

     Description:
     Use the DEADLOCK_TIMEOUT configuration parameter to specify the
     maximum number of seconds that a database server thread can wait
     to acquire a lock.

ROOTNAME                rootdbs
```

The following portion of sample output of the **onstat -g cfg diff** command shows the default, current, and onconfig file values of the TBLTBLFIRST and TBLTBLNEXT configuration parameters:

```
id   name                      type   units   rsvd  tunable
53   TBLTBLFIRST               INT4   KB            *

     default : 500
     onconfig: 0
     current : 250

id   name                      type   units   rsvd  tunable
54   TBLTBLNEXT                INT4   KB            *

     default : 100
     onconfig: 0
     current : 150
```

The following portion of sample output shows information for the MSGPATH configuration parameter. Here, there is no default value that is built into the configuration parameter and the onconfig file and current values are the same.

```
id   name                      type   units   rsvd  tunable
10   MSGPATH                   CHAR           *     *

     default :
     onconfig: /work2/JC/online.log
     current : /work2/JC/online.log
```

The following portion of sample output of the **onstat -g cfg msg** command shows messages that identify configuration parameters with changed values:

```
Configuration Parameters With Messages

name             message
TBLTBLFIRST      Parameter's user-configured value was adjusted.
TBLTBLNEXT       Parameter's user-configured value was adjusted.
BUFFERPOOL       Parameter's user-configured value was adjusted.
STACKSIZE        Parameter's user-configured value was adjusted.
VPCLASS          Parameter's user-configured value was adjusted.
```

Output description

name
: Name of the configuration parameter

type
: Data type for the value

units
: Units in which the value is expressed

rsvd
: Indicates (with an asterisk) that the configuration parameter and its value are stored on the configuration reserved page
If an asterisk is not present, the configuration parameter and its value are not stored on the configuration reserved page.

tunable
: Indicates (with an asterisk) that the configuration parameter can be tuned dynamically, for example, with an **onmode -wm** or **-wf** command
If an asterisk is not present, the configuration parameter cannot be tuned dynamically.

min/max
: Minimum and maximum values for the configuration parameter

default
: Default value that is built into the server for the configuration parameter

onconfig
: Value of the configuration parameter, if any, that is in the onconfig.std file

current
: Current® value of the configuration parameter
A current value is different if it was modified dynamically, for example, with an **onmode -wm** command.

Description
: Description of the configuration parameter

message

Message that identifies a changed configuration parameter value

Related tasks:
Displaying the settings in the onconfig file
Related reference:
onstat -c command: Print ONCONFIG file contents
onmode -wf, -wm: Dynamically change certain configuration parameters
Database server files

onstat -g cluster command: Print high-availability cluster information

Use the **onstat -g cluster** command to display information about the servers in a high-availability cluster environment.

Syntax:

```
>>-onstat-- -g--cluster--+---------+--------------------------><
                         '-verbose-'
```

The **onstat -g cluster** command combines the functionality of **onstat -g dri**, **onstat -g sds**, and **onstat -g rss**. The output of the **onstat -g cluster** command differs slightly depending on whether the command is run on the primary server or on one of the secondary servers.

Example output (primary server)

Following is sample output from the **onstat -g cluster** command. The sample shows output when the command is run on the primary server.

Figure 1. **onstat -g cluster** command output (run on the primary server)

```
Primary Server:serv1
Current Log Page:16,476
Index page logging status: Enabled
Index page logging was enabled at: 2013/12/11 14:05:17

       (log, page)  (log, page)  Updates
serv2  16,476       16,476       Yes          SYNC(SDS),Connected,Active
serv3  16,476       16,476       Yes          ASYNC(HDR),Connected,On
serv4  16,476       16,476       Yes          ASYNC(RSS),Connected,Active
```

Output description (primary server)

Primary server
: The name assigned to the primary server.

Current® log page
: The log ID and page number of the current log page.

Index page logging status
: Indicates whether index page logging is enabled or disabled.

Index page logging was enabled at
: The date and time that index page logging was enabled.

Server
: The name of the secondary server.

ACKed Log (log, page)
: The log ID and page number of the last acknowledged log transmission.

Applied Log (log, page)
: The log ID and page number of the last applied log transmission.

Supports Updates
: Displays whether client applications can perform update, insert, and delete operations on the secondary server (as specified by the UPDATABLE_SECONDARY configuration parameter).

Status
: Displays the connection status of the secondary server

Example output (primary server, verbose output)

Figure 2. **onstat -g cluster verbose** command output (run on the primary server)
Following is sample output from the **onstat -g cluster verbose** command. The sample shows output when the command is run on the primary server with the verbose option.

```
Primary Server:serv1
        Current Log Page:16,479
        Index page logging status: Enabled
        Index page logging was enabled at: 2013/12/11 14:05:17

        ------------------------------------------------------------

        server name: serv3
```

```
        type: ASYNC (HDR)
        control block: 0x4b673018
        server status: On
        connection status: Connected
        Last log page sent (log id, page): 16,479
        Last log page acked (log id, page); 16,479
        Last log page applied (log id, page); 16,479
        Approximate log page backlog: 0
        SDS cycle not used
        Delayed Apply Not Used
        Stop Apply Not Used
        Time of last ack: 2013/12/11 14:09:12
        Supports Updates: Yes

        ------------------------------------------------------------

        server name: serv2
        type: SYNC (SDS)

```

Output description (primary server, verbose output)

Primary server
: The name of the primary server

Current log page
: The log ID and page number of the current log page.

Index page logging status
: Indicates whether index page logging is enabled or disabled.

Index page logging was enabled at
: The date and time that index page logging was enabled.

Server name
: The name of the secondary server.

type
: Displays whether the secondary server is connected synchronously (SYNC) or asynchronously (ASYNC). Also displays the type of secondary server: HDR, SDS, or RSS.

control block
: The in-memory address of the thread control block.

server status
: Displays the current status of the secondary server.

connection status
: Displays the current network connection status of the secondary server.

Last log page sent (log id, page)
: The log ID and page number of the most recent log page sent by the primary server to the secondary server.

Last log page acked (log id, page)
: The log ID and page number of the most recent log page the secondary server acknowledged.

Last log page applied (log id, page)
: The log ID and page number of the most recent log page the secondary server applied.

Approximate log page backlog
: Indicates the approximate number of log pages that have yet to be processed by the secondary server.

SDS cycle
: Indicates the cycle number to which the primary server has advanced and which the shared disk secondary server has acknowledged. Used internally by support to monitor coordination of the primary server with the secondary server.

Delayed Apply
: Indicates whether the secondary server waits for a specified amount of time before applying logs (as specified by the DELAY_APPLY configuration parameter).

Stop Apply
: Indicates whether the secondary server has stopped applying log files received from the primary server (as specified by the STOP_APPLY configuration parameter).

Time of last ack
: The date and time of the last acknowledged log.

Supports Updates
: Displays whether client applications can perform update, insert, and delete operations on the secondary server (as specified by the UPDATABLE_SECONDARY configuration parameter).

Example output (secondary server)

Following is sample output from the **onstat -g cluster** command. The sample shows output when the command is run on a secondary server.

Figure 3. **onstat -g cluster** command output (run on the secondary server)

```
Primary Server:serv1
        Index page logging status: Enabled
        Index page logging was enabled at: 2010/01/11 14:05:17
```

```
        Server ACKed Log    Applied Log   Supports     Status
               (log, page)  (log, page)   Updates
        serv2  16,479       16,479        Yes          SYNC(SDS),Connected,Active
```

Output description (secondary server)

Primary server
The name of the primary server
Index page logging status
Indicates whether index page logging is enabled or disabled.
Index page logging was enabled at
The date and time that index page logging was enabled.
Server
The name of the secondary server.
ACKed Log (log, page)
The log ID and page number of the last acknowledged log.
Applied Log (log, page)
The log ID and page number of the last applied log transmission.
Supports Updates
Displays whether client applications can perform update, insert, and delete operations on the secondary server (as specified by the UPDATABLE_SECONDARY configuration parameter).
Status
Displays the connection status of the secondary server.

onstat -g cmsm command: Print Connection Manager information

Use the **onstat -g cmsm** command to display information about a specific Connection Manager, or all of the Connection Managers that are attached to the database server the command is run on.

Syntax:

```
>>-onstat-- -g--cmsm--+-------------------------+--------------><
                      '-connection_manager_name-'
```

Usage

onstat -g cmsm displays information about connection units the Connection Manager connects to, the number of connections each Connection Manager service-level-agreement (SLA) has processed, SLA definitions, failover-order rules, failover arbitration, and primary server status.

Use *connection_manager_name* to display information for a specific Connection Manager instance. If *connection_manager_name* is not specified, **onstat -g cmsm** displays information about all Connection Manager instances that are connected to the database server.

Example output 1: Output for a specific Connection Manager

In the following example, **onstat -g cmsm connection_manager_1** is run on the primary server of **my_cluster_1**.

```
Unified Connection Manager: connection_manager_1                Hostname: my_host_1

CLUSTER          my_cluster_1       LOCAL
   SLA           Connections    Service/Protocol    Rule
   oltp_1                 35      19910/onsoctcp    DBSERVERS=primary
   report_1               33      19810/onsoctcp    DBSERVERS=(HDR,SDS,RSS)

   Failover Arbitrator: Active Arbitrator, Primary is up
   ORDER=SDS,HDR,RSS PRIORITY=1
```

The command displays output for **connection_manager_1**. **connection_manager_1** manages a CLUSTER connection unit, and is the active failover arbiter.

Example output 2: Output for a high-availability cluster

In the following example, **onstat -g cmsm** is run on the primary server of **my_cluster_2**.

```
Unified Connection Manager: connection_manager_2                Hostname: my_host_2

CLUSTER          my_cluster_2       LOCAL
   SLA           Connections    Service/Protocol    Rule
   sla_1                1535      19910/onsoctcp    DBSERVERS=primary
   sla_2                2133      19810/onsoctcp    DBSERVERS=(HDR,SDS,RSS)

        Failover Arbitrator: Active Arbitrator, Primary is up
        ORDER=SDS,HDR,RSS PRIORITY=1
```

```
CLUSTER         my_cluster_3
   SLA          Connections   Service/Protocol   Rule
   sla_3                730     19930/onsoctcp   DBSERVERS=primary
   sla_4                901     19830/onsoctcp   DBSERVERS=(HDR,SDS,RSS)

   Failover Arbitrator: Active Arbitrator, Primary is up
   ORDER=SDS,HDR,RSS PRIORITY=1

Unified Connection Manager: connection_manager_3               Hostname: my_host_3

CLUSTER         my_cluster_2      LOCAL
   SLA          Connections   Service/Protocol   Rule
   sla_5                614     19920/onsoctcp   DBSERVERS=primary
   sla_6                483     19820/onsoctcp   DBSERVERS=(HDR,SDS,RSS)

   Failover Arbitrator: Failover is enabled
   ORDER=SDS,HDR,RSS PRIORITY=2

CLUSTER         my_cluster_3
   SLA          Connections   Service/Protocol   Rule
   sla_7                678     19940/onsoctcp   DBSERVERS=primary
   sla_8                270     19840/onsoctcp   DBSERVERS=(HDR,SDS,RSS)

        Failover Arbitrator: Failover is enabled
        ORDER=SDS,HDR,RSS PRIORITY=2
```

The command displays output for the two Connection Managers that connect to the primary server of the cluster. **connection_manager_2** and **connection_manager_3** are installed on separate hosts, and together they manage two CLUSTER connection units. **connection_manager_2** is the active failover arbiter for both CLUSTER connection units.

Example 3: Output for a replicate set

In the following example, **onstat -g cmsm** is run on a replicate server in **my_replicate_set_1**.

```
Unified Connection Manager: connection_manager_4               Hostname: my_host_4

REPLSET         my_replicate_set_1
   SLA          Connections   Service/Protocol   Rule
   sla_1                160     19810/onsoctcp   DBSERVERS=ANY

Unified Connection Manager: connection_manager_5               Hostname: my_host_5

REPLSET         my_replicate_set_1
   SLA          Connections   Service/Protocol   Rule
   sla_2                240     19820/onsoctcp   DBSERVERS=ANY
```

The command displays output for the two Connection Managers that connect to the replicate server. **connection_manager_4** and **connection_manager_5** are installed on separate hosts, and together they manage the replication servers.

Example 4: Output for a grid

In the following example, **onstat -g cmsm** is run on a node of **my_grid_1**.

```
Unified Connection Manager: connection_manager_6               Hostname: my_host_6

GRID    my_grid_1
   SLA          Connections   Service/Protocol   Rule
   sla_1                456     19830/onsoctcp   DBSERVERS=(group_name_1,group_name_2) POLICY=FAILURE

Unified Connection Manager: connection_manager_7               Hostname: my_host_7

GRID    my_grid_1
   SLA          Connections   Service/Protocol   Rule
   sla_2                785     19840/onsoctcp   DBSERVERS=(group_name_1,group_name_2) POLICY=FAILURE
```

The command displays output for the two Connection Managers that connect to the grid. The command displays output for the two Connection Managers that connect to the node. **connection_manager_6** and **connection_manager_7** are installed on separate hosts, and together they manage the grid.

Example 5: Output for a server set

In the following example, **onstat -g cmsm** is run on a stand-alone server in the server set.

```
Unified Connection Manager: connection_manager_8                    Hostname: my_host_8

SERVERSET       server_1,server_2
   SLA          Connections   Service/Protocol   Rule
   sla_1                 63     19810/onsoctcp   DBSERVERS=(server_1,server_2) POLICY=ROUNDROBIN

Unified Connection Manager: connection_manager_9                    Hostname: my_host_9

SERVERSET       server_1,server_2
   SLA          Connections   Service/Protocol   Rule
   sla_2                 63     19810/onsoctcp   DBSERVERS=(server_1,server_2) POLICY=ROUNDROBIN
```

The command displays output for the two Connection Managers that connect to the server set. **connection_manager_8** and **connection_manager_9** are installed on separate hosts, and together they manage the server set.

Output description

The output of the **onstat -g cmsm** command contains sections for each Connection Manager. Each section displays the Connection Manager instance name and host name, followed by subsections that contain information on each connection unit the Connection Manager connects to.

Unified Connection Manager
: The name of the Connection Manager instance.

Hostname
: The name of the Connection Manager's host.

SLA
: The names of service level agreements, as defined in the Connection Manager's configuration file.

Connections
: The numbers of connections each SLA processed since the Connection Manager started.

Service/Protocol
: The port number or service name that is associated with the SLA, followed by the connection protocol type.

Rule
: The SLA definition.

Failover Arbitrator:
: Specifies whether the Connection Manager is the active failover arbiter, if the primary server is active, and if failover is enabled. Displays only for CLUSTER connection units.

ORDER
: Specifies the failover order for a cluster. Displays only for CLUSTER connection units.

PRIORITY
: Specifies the priority of the connection between the Connection Manager and the primary server of a cluster. Displays only for CLUSTER connection units.

onstat -g con command: Print condition and thread information

Use the **onstat -g con** command to display information about conditions and the threads that are waiting for the conditions.

Syntax:

```
>>-onstat-- -g--con-------------------------------------------><
```

Example output

Figure 1. **onstat -g con** command output

```
Conditions with waiters:
cid      addr             name             waiter   waittime
271      c63d930          netnorm          1511     6550
```

Output description

cid
: Condition identifier

addr
: Condition control block address

name
: Name of condition the thread is waiting on

waiter
: ID of thread waiting on condition

waittime
: Time, in seconds, thread has been waiting on this condition

onstat -g cpu: Print runtime statistics

Use the **onstat -g cpu** command to display information about runtime statistics for each thread that is running in the server.

Syntax:

```
>>-onstat-- -g--cpu-------------------------------------------><
```

Example output

Figure 1. **onstat -g cpu** command output

```
onstat -g cpu

Thread CPU Info:

Output description

tid
: The ID of the thread

name
: The name of the thread

vp
: The ID of the virtual processor in which the thread is running

Last Run
: The timestamp when the thread last ran

CPU Time
: The time taken until now by the thread

#scheds
: The number of times the thread was scheduled to run

status
: The status of the thread. Possible status values are:

- cond wait
- IO Idle
- join wait
- mutex wait
- ready
- sleeping
- terminated
- running
- yield

onstat -g dbc command: Print dbScheduler and dbWorker thread statistics

Use the **onstat -g dbc** command to display statistics about the Scheduler tasks that are currently running, which are handled by dbWorker threads, or scheduled to be run, which are handled by the dbScheduler thread.

Syntax:

```
>>-onstat-- -g--dbc-----------------------------------------><
```

Example output

Figure 1. **onstat -g dbc** command output

```
Worker Thread(0)    46fa6f10

====================================
Run Queue
    Empty
Run Queue Size         0
Next Task              7
Next Task Waittime    57
```

Output description

Worker Thread
: Address of the worker thread in shared memory

Task
: Name of the last executed task

Task ID
: The task ID from the **tk_id** column in the **sysadmin:ph_task** table for this task

Task Type
: Type of the task

Last Error
: Error number, error message, time (in seconds), and task name from the last error the dbWorker thread encountered. It could be from the previously executed task or from a task executed days ago.

Task Execution
: SQL statement or SPL procedure or routine executed as part of the task

WORKER PROFILE
: The dbWorker thread profile data shows the total jobs executed, number of sensors executed, number of tasks executed, number of purge requests, and the number of rows purged from the result tables for all sensors executed by this dbWorker thread.

Scheduler Thread
: Address of the scheduler thread in shared memory

Run Queue
: The task ID for the next scheduled task. If no task is scheduled, the value is `Empty`.

Run Queue Size
: The number of tasks that are waiting to be executed by the dbWorker thread

Next Task
: The task ID of the next task that will be scheduled to be executed

Next Task Waittime
: The number of seconds before the `Next Task` will be scheduled for execution

Monitor the scheduler

onstat -g defragment command: Print defragment partition extents

Use the **onstat -g defragment** command to display information about the active requests to defragment partition extents.

Syntax:

```
>>-onstat-- -g--defragment-------------------------------------><
```

Example output

Figure 1. **onstat -g defragment** command output

```
Defrag info
id  table name                      tid  dbsnum  partnum  status                substatus  errnum
15  stores_demo:informix.stdtab2    49   2       2097155  SEARCHING_FOR_EXTENT  0          0
```

Note: This command displays information about defragment requests that are active. If there are no active defragment requests, only the column headings are returned.

Output description

id
: The ID of the defragment request.

table name
: The fully-qualified name of the table that is being defragmented.

tid
: The thread ID.

dbsnum
: The dbspace number that is being defragmented.

partnum
: The partition number that is being defragmented.

status
: - SEARCHING_FOR_EXTENT
  - MERGING_EXTENTS
  - DEFRAG_COMPLETED
  - DEFRAG_FAILED

substatus
: The detailed status number, if any.

errnum
: The last error number returned from the defragmentation request.

onstat -g dic command: Print table information

Use the **onstat -g dic** command to display a line of information about each table that is cached in the shared-memory dictionary. If you specify a table name, this command prints internal SQL information about that particular table.

Syntax:

```
>>-onstat-- -g--dic-----------------------------------------><
```

Example output

Figure 1. **onstat -g dic** command output

```
Dictionary Cache:  Number of lists: 31, Maximum list size: 10
list#  size  refcnt  dirty?  heapptr        table name
---------------------------------------------------------
   1     3      1      no     14b5d890   wbe@oninit_shm:informix.t0010url
                1      no     14cbb820   wbe@oninit_shm:informix.t9051themeval

                0      no     14d3d820   contact@oninit_shm:informix.wbtags
                0      no     14c87420   wbe@oninit_shm:informix.wbtags

   4     1      0      no     14b7a420   drug@oninit_shm:abcdef.product      ..
Total number of dictionary entries: 36
```

Output description

list#
: Data dictionary hash chain ID

size
: Number of entries in this hash

refcnt
: Number of SQL statements currently referencing one of the cache entries.

dirty?
: Whether the entry has been modified since last written to disk.

heapptr
: Address for the heap used to store this table

table name
Name of table in cache

onstat -g dis command: Print database server information

Use the **onstat -g dis** command to display a list of database servers, the status of each server, and information about each server, including the location of the **INFORMIXDIR** directory, **sqlhosts** file, and ONCONFIG file. You can use this command in any database server mode, including offline.

Syntax:

```
>>-onstat-- -g--dis-----------------------------------------><
```

Example output

Figure 1. **onstat -g dis** command output

```
There are 2 servers found
Server         : ol_tuxedo
Server Number  : 53
Server Type    : IDS
Server Status  : Up
Server Version: IBM Informix Version 11.50.UC1
Shared Memory  : 0xa000000
INFORMIXDIR    : /local1/engines/ol_tuxedo/dist
ONCONFIG       : /local1/engines/ol_tuxedo/dist/etc/onconfig.ol_tuxedo
SQLHOSTS       : /local1/engines/ol_tuxedo/dist/etc/sqlhosts
Host           : avocet

Server         : ol_9next
Server Number  : 0
Server Type    : IDS
Server Status  : Down
Server Version:
Shared Memory  : 0
INFORMIXDIR    : /local1/engines/ol_9next/dist
ONCONFIG       :
SQLHOSTS       :
Host           :
```

Output description

Server
Server name
Server Number
Number of the server.
Server Type
Type of server
Server Status
Up means that the server is online, Down means that the server is offline
Server Version
Version of the server
Shared Memory
Location of the shared memory address
INFORMIXDIR
Location of the **$INFORMIXDIR/** directory on UNIX and in the **%INFORMIXDIR%** directory on Windows.
ONCONFIG
Location of the ONCONFIG file
SQLHOSTS
Location of the **sqlhosts** file
Host
Host name of the server

onstat -g dll command: Print dynamic link library file list

Use the **onstat -g dll** command to display a list of and the status of dynamic link library (DLL) files that were loaded.

Syntax:

```
>>-onstat-- -g--dll-----------------------------------------><
```

Example output

The output displays the names of the library files only one time each process group. The flags indicate if the library was loaded when the server was started.
Figure 1. **onstat -g dll** command output

```
addr             slot   vp baseaddr         flags    filename
0x4af55310       15     1  0x2a985e3000     PM       /finance/jeffzhang/mylib.udr
0x4b6f2310              2  0x2a985e3000
0x4b71b310              3  0x2a985e3000
0x4c09f310       16     1  0x2a985e3000     M        /deptxyz/udrs/geodetic.bld
0x4c0c0310              2  0x2a985e3000
0x4c0f1310              3  0x2a985e3000
0x4c112310       17     1  0x7a138e9000              /home/informix/extend/blade.so
0x4c133310              2  0x3a421e1000
0x4c133310              3  0x3a421e1000
```

Output description

addr
: Address of the DLL file

slot
: Slot number entry in the library table

vp
: ID of the virtual processor

baseaddr
: Base address of the shared library

flags

- M indicates that the thread calling the UDR can migrate from one CPU virtual processor to another CPU virtual processor.
- P indicates that the shared library was loaded when the database server was started.

filename
: Name of the DLL file

Related reference:
PRELOAD_DLL_FILE configuration parameter

onstat -g dmp command: Print raw memory

Use the **onstat -g dmp** command to display information about raw memory at a given address for a number of given bytes.

Syntax:

```
>>-onstat-- -g--dmp--address--length---------------------------><
```

Each address and length must be within the allocated memory shown from **onstat -g seg** output. The address specified can be in decimal or hexadecimal format. Hexadecimal addresses must begin with **0x**. You can specify the address in decimal, but doing so requires converting the memory shown from **onstat -g seg** to decimal before using it as a command line argument.

Example output

Figure 1. **onstat -g dmp** command output

```
%onstat -g dmp 0x700000011a19d48 100

address           bytes in mem
0700000011a19d48: 07000000 118e0fa8 07000000 11942b40 ........ ......+@
0700000011a19d58: 07000000 10137120 00000000 00000000 ......q  ........
0700000011a19d68: 00000000 00000000 00000000 00000000 ........ ........
0700000011a19d78: 07000000 11a19d48 07000000 11a19d48 .......H .......H
0700000011a19d88: 00000000 00000000 00000000 00000000 ........ ........
0700000011a19d98 *
0700000011a19da8: 00000000 ....
```

Output description

address
: Memory address of the raw memory.

bytes in mem
: Hexadecimal and ASCII representations of the memory contents.

Output from the command is divided into three columns: memory address, hexadecimal values for the bytes in memory, and the ASCII representation of the bytes in memory. The bytes in memory (middle) section displays the first 16 bytes of memory starting at the address specified on the command line. The third column shows the ASCII representation of the hexadecimal data. Periods are displayed for all hexadecimal values that do not have an ASCII character equivalent. ASCII values are shown in order to make searching for plain text easier.
In the example output shown, the fifth line of data displays zeros and the sixth line contains an asterisk. The asterisk indicates an unknown number of repetitions of the previous line, which means that there is no more data after the fourth line.

onstat -g dri command: Print high-availability data replication information

Use the **onstat -g dri** command, either alone or with the **ckpt** or **que** options, to print information about high-availability data replication statistics on the current server.

Use the **onstat -g dri** command to print information about HDR server states and HDR-related configuration parameters.

Syntax:

```
>>-onstat-- -g--dri--+------+---------------------------------><
                    +-ckpt-+
                    '-que--'
```

Example output and output description for onstat -g dri

Figure 1. **onstat -g dri** command output

```
Data Replication at 0x4d676028:
  Type            State         Paired server        Last DR CKPT (id/pg)    Supports Proxy Writes
  primary         on            my_server                  4 / 5              NA

  DRINTERVAL   5

  Last Receive 2013/12/11 16:39:48
  Last Ping    2013/12/11 16:39:44
  Last log page applied(log id,page): 4,6
```

Type
: Current® type of server: primary, secondary, or standard

State
: on or off

Paired server
: Name of the primary or secondary server that this server is paired with

Last DR CKPT
: Last checkpoint ID and page

Supports Proxy Writes
: Displays whether the server is configured to allow secondary server updates. **Y** = supports secondary server updates, **N** = does not support secondary server updates.

DRINTERVAL
: The value of the configuration parameter in the onconfig file.

DRTIMEOUT
: The value of the configuration parameter in the onconfig file.

DRAUTO
: The value of the configuration parameter in the onconfig file.

DRLOSTFOUND
: The value of the configuration parameter in the onconfig file.

DRIDXAUTO
: The value of the configuration parameter in the onconfig file.

ENCRYPT_HDR
: The value of the configuration parameter in the onconfig file.

Backlog
: Number of log pages in the HDR data replication buffer that are not yet sent to the HDR secondary server

Last Send
: The time that the last message was sent to the peer node

Last Receive
: The time that the last message was received from the peer node

Last Ping
: The time of the last ping

Last log page applied(log id,page)
: The log ID and page number of the last applied log

Example output and output description for onstat -g dri ckpt

Use the **onstat -g dri ckpt** command to print information about nonblocking checkpoints in HDR servers.

Figure 2. **onstat -g dri ckpt** command output

```
Data Replication:
  Type            State         Paired server        Last DR CKPT (id/pg)   Supports Proxy Writes
  primary         on            BB_1                       554 / 558       Y

  DRINTERVAL   30
  DRTIMEOUT    30
```

```
  DRAUTO       0
  DRLOSTFOUND  /vobs/tristarm/sqldist/etc/dr.lostfound
  DRIDXAUTO    0
  ENCRYPT_HDR  0
DR Checkpoint processing:
  Save State               N
  Pages Saved              0
  Save Area                none
  Received log id, page    17,68
  Saved log id, page       0,0
  Drain log id, page       0,0
  Processed log id, page   17,68
  Pending checkpoints      0
```

Save State
: **B** (buffering) when the server is adding logs to the staging area
: **D** (draining) when the server is removing logs from the staging area
: **N** (normal) when the server is operating normally, meaning that no logs are saved

Pages Saved
: Displays the number of log pages saved in the staging area that have yet to be applied.

Save Area
: Displays the location of the staged log files.

Received log id, page
: Displays the last log ID and page that were received from the primary server.

Processed log id, page
: Displays the last log ID and page that are queued to the recovery pipeline.

Saved log id, page
: Displays the last log ID and page that was stored in the staging area (if stage state is either **B** or **D**).

Drain log id, page
: Displays the last log ID and page that were removed from the staging area.

Pending checkpoints
: Displays the number of checkpoints that are staged but not yet applied.

Pending ckpt log id, page
: Displays the position of any pending checkpoint records.

Example output and output description for onstat -g dri que

Use the **onstat -g dri que** command to print information that is related to nearly synchronous HDR replication.

Figure 3. **onstat -g dri que** command output

Total number of distribution entries: 58
    Number of entries in use        : 0
```

Output description

Number of lists
: Number of lists in the distribution cache

DS_POOLSIZE
: Number of entries that can be cached at one time

list
: Distribution cache hash chain ID

id
: Number of hash entries

ref
: Number of statements that reference a cache entry

drop
: Whether this entry was dropped after it was added to the cache

hits
: The number of times the cache entry is accessed.

last_access
: The time at which the cache entry was last accessed.

heap_ptr
: Heap address that is used to store this entry

distribution name
: The name of the distribution in the cache

Total number of distribution entries
: Number of entries in the distribution cache

Number of entries in use
: Number of entries that are being used

onstat -g dsk command: Print the progress of the currently running compression operation

Use the **onstat -g dsk** command to print information that shows the progress of currently running compression operations, such as compress, repack, and shrink.

Syntax:

```
>>-onstat-- -g -dsk-------------------------------------------><
```

Example output

Figure 1. **onstat -g dsk** command output for a compress operation

```
                    Processed        Remaining Duration Remaining
Partnum    OP       Rows       Blobs Rows      Time(s)  Time(s)   Table Name
400002     Compress 6325       1752  1497      00:00:00 00:00:00 db:sl:t1
```

Figure 2. **onstat -g dsk** command output for a repack operation

```
                          Processed        Remaining Duration Remaining
Partnum   OP     Pass     Rows       Blobs Rows      Time(s)  Time(s)   Table Name
400002    Repack 1        6325       1752  1497      00:00:00 00:00:00 db:sl:t1
```

Output description

partnum
: Partition number of the table or fragment

OP
: Compression operation, such as compress, repack, or shrink.

Pass
: For repack operations, 1 indicates the first pass of reading the rows, and 2 indicates the second pass.

Processed Rows
: Number of rows that are processed so far for the specified operation

Blobs
: The number of simple large objects that were operated on

Remaining Rows
: The number of remaining rows to process. For repack operations, the number of rows that remain in the current pass.

Duration Time(s)
: The amount of time since the beginning of the operation

Remaining Time(s)
: Approximate amount of remaining time for the operation. For repack operations, the amount of time that remains for the current pass.

onstat -g env command: Print environment variable values

Use the **onstat -g env** command to display the values of the environment variables that the database server currently uses.

Syntax:

```
>>-onstat-- -g--env--+------------------------+---------------><
                    +-all--------------------+
                    +-variable---------------+
                    '-sessionid--+----------+-'
                                 '-variable-'
```

You can specify one of the following invocations.

Invocation	Explanation
onstat -g env	Displays the settings of environment variables when the database server was started Does not display environment variables that have not been set explicitly.
onstat -g env all	Displays the settings used by all sessions This display is the same as the output of **onstat -g env** and **onstat -g env*sessionid*** iteratively on all current sessions.
onstat -g env *variable*	Displays the default value of the specified environment variable This ***variable*** argument eliminates the need to pipe the output to **grep** (or some other utility) to locate an environment variable among many that might be set.
onstat -g env *sessionid*	Displays the settings that a specific session uses. This display includes the following values: • Set in the environment of the session • Assigned by the database server, as **onstat -g env** displays
onstat -g env *sessionid variable*	Displays the value of the specified environment variable that the specified session uses The ***sessionid*** and ***variable*** arguments eliminate the need to pipe the output to **grep** (or some other utility) to locate an environment variable among many that might be set.

The **onstat -g env** command displays the current setting of an environment variable and the complete list of values each time the variable was set in the environment. For example, if PDQPRIORITY is set to `10` in the **.informix.rc** file and set to `55` in the shell environment, **onstat -g env** command displays both values.

However, if you change the PDQPRIORITY with the **onmode -q pdqpriority *sessionid*** command, the **onstat -g env** command does not display the new value for the session. The **onstat -g env** command displays only the values of environment variables set in the environment. It does not display values modified while the session is running.

You might want to display the values of environment variables in the following situations:

- The database server instance has been up for months, and you cannot remember the setting of an environment variable (such as the server locale setting **SERVER_LOCALE**).
- You want to display the complete list of values for an environment variable to identify when an environment variable has been set in multiple places.
- Environment files on disk might have changed or been lost in the interim.

- A support engineer wants to know settings of specific environment variables.

Example output

The following figure shows the output for the **onstat -g env** command.
Figure 1. **onstat -g env** command output

onstat -g ffr command: Print free fragments

Use the **onstat -g ffr** command to display information about the free memory fragments for a specified session or shared-memory pool.

This command requires an additional argument to specify either a pool name or session ID whose memory pool information is to be displayed. Each session is allocated a memory pool with the same name as the session ID. Use the **onstat -g mem** command to identify the pool name and the **onstat -g ses** command to identify the session ID.

Syntax:

```
>>-onstat-- -g--ffr--+-pool name-+-----------------------------><
                     '-sessionid-'
```

Example output

Figure 1. **onstat -g ffr aio** command output

```
Free lists for pool name aio:
addr      size      idx
165dcfa0  96        10
1659cf68  152       17
165b2f20  224       26
165c7f20  224       26
1666ec38  968       79
149f2ba0  1120      84
```

Output description

addr (hexadecimal)
: Memory address of the pool fragment.

size (decimal)
: Size, in bytes, of the pool fragment.

idx (decimal)
: For internal use. Index in the array of free list pointers.

onstat -g glo command: Print global multithreading information

Use the **onstat -g glo** command to display global information about multithreading, information about each virtual processor that is running, and cumulative statistics for each virtual-processor class. This information includes CPU use information about the virtual processors, the total number of sessions, and other multithreading global counters.

Syntax:

```
>>-onstat-- -g--glo-------------------------------------------><
```

Example output

Figure 1. onstat -g glo command output

```
MT global info:
sessions threads  vps      lngspins time
0        23       14       0        142

```

Output description

The following table explains each column in the global information section of the example output.

Table 1. Description of the columns in the virtual processor summary

Column name	Description
sessions	The number of sessions
threads	The total number of threads
vps	The total number of virtual processors
lngspins	The number of times a thread had to spin more than 10,000 times to acquire a latch on a resource
time	The number of seconds over which the statistics were gathered. Statistics start when the server starts or the statistics are reset by running the **onstat -z** command.
sched calls	The total number of scheduled calls.
thread switches	The total number of switches from one thread to another.
yield	Statistics on thread yields, which occur when a thread can no longer continue its task until some condition occurs

The following table explains each column in the virtual processor summary section of the example output.

Table 2. Description of the columns in the virtual processor summary

Column name	Description
class	The type of virtual processor.
vps	The number of instances of the class of virtual processor.
usercpu	The total user time, in seconds, that the class of virtual processor spent running on the CPU.

Column name	Description
syscpu	The total system time, in seconds, the class of virtual processor spent running on the CPU.
total	The total CPU time for the virtual processor class, as the sum of the user time plus the system time.

The following table explains each column in the individual virtual processors section of the example output.

Table 3. Description of the columns for the individual virtual processors

Column name	Description
vp	The virtual processor number. On Windows, the values are thread IDs.
pid	The Process ID of the **oninit** process.
class	The type of virtual processor.
usercpu	The total user time, in seconds, that the virtual processor spent running on the CPU.
syscpu	The total system time, in seconds, that the virtual processor spent running on the CPU.
total	The total CPU time for the virtual processor, as the sum of the user time plus the system time.
Thread	The total time the threads ran on the virtual processor.
Eff	Efficiency. The ratio of the total CPU time to the total time the threads ran on the virtual processor.

onstat -g his command: Print SQL trace information

Use the **onstat -g his** command to display SQL trace information from the collection of **syssqltrace** tables (syssqltrace, syssqltrace_info, syssqltrace_hvar and syssqltrace_itr) in the **sysmaster** database.

The **level** setting of the SQLTRACE configuration parameter affects what SQL trace information is stored and displayed by the set of **syssqltrace** tables, and what information **onstat -g his** displays. Each row of the **syssqltrace** table describes a previously executed SQL statement. By default, only the DBSA can view the **syssqltrace** information from the **onstat -g his** command. However, when the UNSECURE_ONSTAT configuration parameter is set to `1`, all users can view this information.

Syntax:

```
>>-onstat-- -g--his-------------------------------------------><
```

Example output

The content of the output depends on the trace settings.

The **Statement history** section in the output provides information about the current settings for tracing.

```
Statement history:

Trace Level                 Low
Trace Mode                Global
Number of traces            1000
Current Stmt ID                2
Trace Buffer size           2008
Duration of buffer           293 Seconds
Trace Flags           0x00001611
Control Block         0x4c2f0028
```

The following table describes this output:

Information	Description
Trace Level	Amount of information traced. Valid values are LOW, MED, HIGH, and OFF.
Trace Mode	Type of tracing performed. Global refers to all users on the system User refers to only those users who have tracing enabled by an SQL administration API function.
Number of traces	The number of SQL statements that are being traced. This is the value set in your onconfig file unless the ntraces parameter is changed dynamically through SQL Administration API functions. The range is 500 to 2147483647. If you have 100,000 trace buffers and your organization runs 1000 SQL statements a second, and are tracing all of the statements, then the buffers would last for 100 seconds before they would begin being overwritten.
Current® Stmt ID	The ID for the current SQL statement. Each statement being traced gets a unique ID.
Trace Buffer size	The amount of data each trace buffer will capture, in bytes. If you set the size to 2KB, but have an SQL statement that is 12KB, the statement is truncated by at least 10KB. More data might be truncated, depending on what else is being traced.
Duration of buffer	The amount of time, in seconds, that the trace data in the current trace buffer spans. This is not how long the **sqltrace** feature has been running. In the above example **Duration of buffer** is 293 seconds which indicates the number of seconds between the first and last SQL statement that are traced.
Trace Flags	The current SQL trace flags that are set.
Control Block	The memory address of the SQL trace control block.

The information displayed below is repeated one time for each time a statement was run. In this example there are two variables being called.

```
Statement # 2:      @ 0x4c2f3028

Database:         sysmaster
```

```
Statement text:
  select count(*) from systables,syscolumns where systables.tabid > ? and
    systables.nrows < ?

  SELECT using tables [ systables syscolumns ]
```

The following table describes this output:

Information	Description
Database	The name of the database or part number of the **systables** entry for the database.
Statement text	The statement text for this SQL statement. If the statement is a stored procedure, then the statement text would display the procedure stack trace. The statement text might be truncated if the statement and the numeric statistics are larger than the trace buffer.

```
Iterator/Explain
================
ID    Left  Right   Est Cost   Est Rows   Num Rows   Partnum   Type
 3       0      0         17         42        146   1048579   Index Scan
 4       0      0       5249       2366       2366   1048580   Seq Scan
 2       3      4       5266      99372     345436         0   Nested Join
 1       2      0          1          1          1         0   Group
```

The following table describes this output:

Information	Description
ID	SQL iterator ID
Left	ID of the left input to the iterator
Right	ID of the right input to the iterator
Est Cost	Estimated cost of this iterator
Est Rows	Estimated rows for this iterator
Num Rows	Actual number of rows for this iterator
Partnum	The table or index partition number.
Type	Type of operation

If the SQL statement contains one or more variables, and you are tracing host variables, the **Host Variables** section is included in the output.

```
Host Variables
==============
1 integer    100
2 float      1000.0000000000000000
```

The following table describes this output:

Information	Description
Column 1	The position of the variable in the statement.
Column 2	The data type of the variable.
Column 3	The value of the variable.

```
Statement information:
  Sess_id  User_id  Stmt Type  Finish Time   Run Time   TX Stamp  PDQ
  5        2053     SELECT     01:08:48      0.4247     340a6e9    0
```

The following table describes this output:

Information	Description
Sess_id	The session ID
User_id	The operating system user ID
Stmt Type	The type of SQL statement
Finish Time	The time of day that the SQL statement finished
Run Time	The total amount of time consumed by the virtual processors or threads used to process the statement. For example, if the Finish Time is 1:15:00 and the Run Time is 9 minutes and the start time is not necessarily 1:06:00. There might be multiple virtual processors or threads involved in processing parts of the statement in parallel.
TX Stamp	The time the BEGIN WORK statement was logged in this transaction
PDQ	The SQL statement PDQ level

The **Statement Statistics** section in the output provides specific information about the statement.

```
  Statement Statistics:
  Page       Buffer     Read       Buffer     Page       Buffer     Write
  Read       Read       % Cache    IDX Read   Write      Write      % Cache

```

Information	Description
Page Read	Number of pages that have been read from disk for this SQL statement
Buffer Read	Number of times a page has been read from the buffer pool and not read from disk for this SQL statement
Read % Cache	Percentage of times the page was read from the buffer pool
Buffer IDX Read	This Currently not implemented
Page Write	Number of pages written to disk
Buffer Write	Number of pages modified and sent back to the buffer pool
Write % Cache	Percentage of time that a page was written to the buffer pool but not to disk
Lock Requests	Total number of locks required by this statement
Lock Waits	Number of times this SQL statement waited on locks
LK Wait Time (S)	Amount of time the statement waited for application locks, in seconds
Log Space	Amount of storage space that the SQL statement used in the logical log
Num Sorts	Total number of sorts used to execute the statement
Disk Sorts	Number of sorts which required disk space to execute the sort for this SQL statement
Memory Sorts	Number of sorts executed which executed entirely in memory for this SQL statement
Total Executions	Total number of times this prepared statement has been executed, or the number of times this cursor has been re-used
Total Time (S)	Total time this prepared statement ran, in seconds
Avg Time (S)	Average time this prepared statement required to execute, in seconds
Max Time (S)	Total time to run the prepared SQL statement, in seconds, excluding any time taken by the application. If you prepare a query then run the query 5 times, each time the query is run a trace is added to the trace buffer. The Max Time is the maximum time any one execution took.
Avg IO Wait	Average amount of time the statement waited for I/O, excluding any asynchronous I/O
I/O Wait Time (S)	Amount of time the statement waited for I/O, excluding any asynchronous I/O, in seconds
Avg Rows Per Sec	Average number of rows a second produced by this statement
Estimated Cost	The query optimizer cost associated with the SQL statement
Estimated Rows	Number of rows returned by the statement, as estimated by the query optimizer
Actual Rows	Number of rows returned for this statement
SQL Error	The SQL error number
ISAM Error	The RSAM or ISAM error number
Isolation Level	Isolation level this statement was run with
SQL Memory	Number of bytes this SQL statement required

For the complete schema of the **syssqltrace** System Monitoring Interface table, see syssqltrace.

For details of setting the SQLTRACE configuration parameter, see SQLTRACE configuration parameter.

Output description

For a description of each output column, see the individual onstat -g iob command: Print big buffer use summary, onstat -g ioq command: Print I/O queue information, and onstat -g iov command: Print AIO VP statistics commands.

onstat -g iob command: Print big buffer use summary

Use the **onstat -g iob** command to display a summary of big buffer use.

Syntax:

```
>>-onstat-- -g--iob-----------------------------------------><
```

Example output

Figure 1. **onstat -g iob** command output

```
AIO big buffer usage summary:
                reads                                      writes

```

onstat -g iof command: Print asynchronous I/O statistics

Use the **onstat -g iof** command to display the asynchronous I/O statistics by chunk or file.

This command is similar to the **onstat -D** command, except that **onstat -g iof** also displays information on nonchunk files. It includes information about temporary files and sort-work files.

Syntax:

```
>>-onstat-- -g--iof-----------------------------------------><
```

Example output

Figure 1. **onstat -g iof** command output

```
AIO global files:
gfd pathname      bytes read   page reads   bytes write   page writes  io/s
3   rootdbs       1918976      937          145061888     70831        36.5

      op type     count        avg. time
      seeks       0            N/A
      reads       937          0.0010
      writes      4088         0.0335
      kaio_reads  0            N/A
      kaio_writes 0            N/A
```

Output description

gfd
: Global file descriptor number for this chunk or file.

pathname
: The pathname of the chunk or file.

bytes read
: Number of byte reads that have occurred against the chunk or file.

page reads
: Number of page reads that have occurred against the chunk or file.

bytes write
: Number of byte writes that have occurred against the chunk or file.

page writes
: Number of page writes that have occurred against the chunk or file.

io/s
: Number of I/O operations that can be performed per second. This value represents the I/O performance of the chunk or file.

op type
: Type of operation.

count
: Number of times the operation occurred.

avg time
: Average time the operation took to complete.

onstat -g iog command: Print AIO global information

Use the **onstat -g iog** command to display global information about AIO.

Syntax:

```
>>-onstat-- -g--iog-----------------------------------------><
```

Example output

Figure 1. **onstat -g iog** command output

```
AIO global info:
   8 aio es
   5 open files
  64 max global files
```

onstat -g ioq command: Print I/O queue information

Use the **onstat -g ioq** command to display statistics about the number and types of operations performed by I/O queues.

Syntax:

```
>>-onstat-- -g--ioq--+------------+----------------------------><
                    '-queue_name-'
```

If a *queue_name* is given then only queues with that name are shown. If no *queue_name* is given then information is given for all queues.

Example output

Figure 1. **onstat -g ioq** command output

```
AIO I/O queues:
q name/id    len maxlen totalops  dskread dskwrite  dskcopy

```

Output description

q name/id
: The name and number of the I/O queue. The name indicates what type of queue it is. The number is used to tell queues of the same name apart. Here is a list of the possible queue names and what each type of queue handles:

  sqli_dbg
  : Handles I/O for Technical Support's SQL Interface Debugging feature

  fifo
  : Handles I/O for FIFO VPs

  adt
  : Handles auditing I/O

msc
: Handles miscellaneous I/O

aio
: Handles IBM® Informix® asynchronous I/O

kio
: Handles kernel AIO

pio
: Handles physical logging I/O

lio
: Handles logical logging I/O

gfd
: Global File Descriptor - Each primary and mirror chunk is given a separate global file descriptor. Individual gfd queues are used depending on whether kaio is on and the associated chunk is cooked or raw.

len
: The number of pending I/O requests in the queue

maxlen
: The largest number of I/O requests that have been in the queue at the same time

totalops
: The total number of I/O operations that have been completed for the queue

dskread
: Total number of completed read operations for the queue

dskwrite
: Total number of completed write operations for the queue

dskcopy
: Total number of completed copy operations for the queue

onstat -g ipl command: Print index page logging status information

Use the **onstat -g ipl** command to display information about the status of index page logging.

Syntax:

```
>>-onstat-- -g--ipl-----------------------------------------><
```

Example output

Figure 1. **onstat -g ipl** command output

```
Index page logging status: Enabled
Index page logging was enabled at: 2008/12/20 16:01:02
```

Output description

Index page logging status
: Status of index page logging: Enabled or Disabled.

Index page logging was enabled at
: The date and time at which index page logging was enabled.

onstat -g iov command: Print AIO VP statistics

Use the **onstat -g iov** command to display asynchronous I/O statistics for each virtual processor.

Syntax:

```
>>-onstat-- -g--iov-----------------------------------------><
```

Example output

Figure 1. **onstat -g iov** command output

```
AIO I/O vps:
class/vp/id  s  io/s  totalops  dskread dskwrite  dskcopy  wakeups  io/wup  errors tempops

```

Output description

class
: The class of the virtual processor.

vp
: The ID number of the virtual processor within its class.

s
: Current® status of the AIO virtual processor

  f
  : Fork

  i
  : Idle

  s
  : Search

  b
  : Busy

  o
  : Open

  c
  : Close

io/s
: The average I/O speed (measured in operations per second) for the virtual processor since the time the database server started or since the **onstat -z** command was last run, whichever happened last.

totalops
: Total number of I/O operations performed by this virtual processor since the time the database server started or since the **onstat -z** command was last run, whichever happened last.

dskread
: Total number of read operations performed by this virtual processor since the time the database server started or since the **onstat -z** command was last run, whichever happened last.

dskwrite
: Total number of write operations performed by this virtual processor since the time the database server started or since the **onstat -z** command was last run, whichever happened last.

dskcopy
: Total number of copy operations performed by this virtual processor since the time the database server started or since the **onstat -z** command was last run, whichever happened last.

wakeups
: For AIO VPs, the number of times the virtual processor has gone idle since the time the database server started or since the **onstat -z** command was last run, whichever happened last.

io/wup
: For AIO VPs, the average number of I/O operations performed per wake-up by this virtual processor since the time the database server started or since the **onstat -z** command was last run, whichever happened last.

errors
: Total number of KAIO out of resource errors.

tempops (decimal)
: For internal use only. This is I/O operation counter that is maintained to determine when a new AIO VP should be added. It is applicable only when the AUTO_AIOVPS configuration parameter is enabled.

---

onstat -g lap command: Print light appends status information

Use the **onstat -g lap** command to display information about the status of light appends occurring in the system.

Syntax:

```
>>-onstat-- -g--lap-----------------------------------------><
```

Example output

Figure 1. **onstat -g lap** command output

```
Light Append Info
session id  address   cur_ppage   la_npused   la_ndata    la_nrows    bufcnt
31          b60a5e8   ffbff494    2938        2937        93990       4
```

Output description

Session id (decimal)
: Session ID performing the light append operation

address (hexadecimal)

Address of the light append buffer

cur_ppage (hexadecimal)
Current® physical page address

la_npused (decimal)
Number of pages allocated

la_ndata (decimal)
Number of data pages appended

la_nrows (decimal)
Number of rows appended

bufcnt (decimal)
Number of light append buffers

onstat -g laq command: Print log apply queues

Use the **onstat -g laq** command to print information about log recovery apply queues.

Use the onstat -g laq command to print information about log recovery apply queues. This includes logical log recovery on secondary servers as well as logical restore or logical recovery part of fast recovery. Log records from logical logs are assigned to replay worker threads according to the tablespace ID (partnum) associated with them; a subset of log records will be applied by the replay master thread.

For instance, in a high-availability cluster, the primary server sends log records to one or more secondary servers over the network. Each secondary server continuously replays the transaction logs from the primary server to ensure that data is replicated on the secondary server. Each tblspace on the primary server is assigned a queue on the secondary server in which to receive log records. A replay thread applies the log records stored in the queue to the secondary server. The log records are applied in the order in which they were received.

You use the **onstat -g laq** command to monitor the performance of the log apply queues, on a secondary server or during any other form of log recovery. Use this command if you suspect that the primary server performance is slowed because logs are not replaying quickly enough on the secondary server, or to monitor the progress made during logical restore. The Avg Depth (average depth) column indicates the average number of log records in the queue(Queue Size) incurred whenever putting a new log record on a queue. The Current/Last LSN column specifies the log record a replay thread currently is active on, or the last one it was replaying, with the Partval column typically specifying the tablespace ID this log record refers to. Transaction pointer and ID shown for a replay thread indicate a log record currently being applied.

When used in repeat mode, using -r [<seconds>][.<fraction>] option, an overall log record apply rate is calculated and shown.

On a secondary server, the transaction latency measured, in full seconds, with each end-of-transaction(COMMIT, ROLLBACK) log record as difference between local apply time and primary server's EoT time, is shown.

The **onstat -g laq** command is valid only when some form of logical log recovery is going on, otherwise only an **onstat** header is printed.

Syntax:

```
>>-onstat-- -g-- laq ------------------------------------------><
```

Example output

Figure 1. **onstat -g laq -r .3** command output from a remote standalone secondary server

```

```

Output description

Thread
The name of the apply thread for a given log record queue.

Queue Size
The number of log records queued for a given apply thread.

Total Queued
The total number of queued log records for a given apply thread.

Avg Depth
: The average number of logs in the queue at the time a queue insert operation occurred.

Secondary Apply Queue
: The secondary apply queue receives log buffers from the primary server. The values displayed represent the total number of buffers allocated to receiving log buffer records(SEC_DR_BUFS), the size of the buffers(LOGBUFF), and the number of currently unused buffers.

Log Recovery Queue
: The log recovery queue receives output from the secondary apply queue. The log buffers are converted to a format compatible with the **ontape** utility. The values displayed represent the total number of stream buffers in the recovery queue, the size of the stream buffers(LTAPEBLK), and the number of unused buffers.

Log Page Queue
: The log page queue receives output from the log recovery queue. The **ontape** formatting is removed and the data is divided into individual log pages. The values displayed represent the total number of log pages in the queue, the size of the queue, and the number of unused buffers.

Log Record Queue
: The log record queue receives output from the log page queue. The log pages are divided into individual log records. The values displayed represent the total number of log records in the recovery queue, the size of the queue, and the number of unused buffers.

Transaction Latency
: Time difference between last replayed transaction commit time at primary server and local server. For this to be accurate, operating system time must match between primary and secondary servers.

Apply rate
: Number of log records replayed per second. Apply rate is only shown with -r option.

onstat -g lmm command: Print low memory management information

Use the **onstat -g lmm** command to display information about automatic low memory management settings and recent activity.

Syntax:

```
>>-onstat-- -g lmm-----------------------------------------------><
```

Example output

Figure 1. **onstat -g lmm** command output

```

Total Killed 177
```

Output description

Control Block
: Address of the internal control structure for automatic low memory management

Memory Limit
: Amount of memory to which the server is attempting to adhere

Used
: Amount of memory currently used by the server

Start Threshold
: Value for the automatic low memory management start threshold

Stop Threshold
: Value for the automatic low memory management stop threshold

Idle Time

The amount of time after which automatic low memory management considers a session idle

Internal Task
: Yes = using Informix® procedures
No = using user-defined procedures

Task Name
: Name of user-defined procedure

Low Mem TID
: Address of the automatic low memory management thread

Task
: Kill = Automatic processes ran and terminated sessions.
Reconfig(reduce) = Automatic processes ran and freed blocks of unused memory.
Reconfig(restore) = Automatic processes ran and restored services and configuration.

Count
: Number of times that the task ran

Last Run
: Date and time when the last task ran

Ses ID
: ID of session that was terminated (with an **onmode –z** command)

Username
: User name of the owner of the session

Hostname
: Name of the host where the session originated

PID
: Process ID

Time
: Date and time when the session was terminated

You use the LOW_MEMORY_MGR configuration parameter to enable the automatic low memory management.

onstat -g lmx command: Print all locked mutexes

Use the **onstat -g lmx** command to display information about all locked mutexes.

Syntax:

```
>>-onstat-- -g--lmx-----------------------------------------><
```

Example output

Figure 1. onstat -g lmx command output

```
Locked mutexes:
mid      addr              name              holder   lkcnt  waiter   waittime
119006   7000001e684b928   td_mutex          298      0
134825   7000002043a9148   free_lock         11009    0      200      22921
                                                             11010    22918
587817   70000022ddb3268   sync_lock1        200      0
593614   700000239ce7b68   SB_LTH_LATCH      875      0

Number of mutexes on VP free lists: 49
```

Output description

mid
: Internal mutex identifier

addr
: Address of locked mutex

name
: Name of the mutex

holder
: Thread ID of the thread that is holding the mutex
0 = The read/write mutex is held in shared mode

lkcnt
: For a read/write mutex, the current number of threads that are locking the mutex in shared mode. For a relockable mutex, the number of times the mutex was locked or relocked by the thread that is holding the mutex.

waiter
: List of IDs of the threads that are waiting for this mutex

waittime

Amount of time in seconds that the thread is waiting

onstat -g lsc command: Print active light scan status (deprecated)

The **onstat -g lsc** command has been superseded by the **onstat -g scn** command.

Syntax:

```
>>-onstat-- -g--lsc---------------------------------------------><
```

Example output

Figure 1. **onstat -g lsc** command output

```
Light Scan Info
descriptor  address           next_lpage  next_ppage        ppage_left  bufcnt  look_aside
3           474b74b0          4a0         7e2c80            416         1            N
```

Output description

descriptor (decimal)
: Light scan ID

address (hex)
: Memory address of the light scan descriptor

next_lpage (hex)
: Next logical page address to scan

next_ppage (hex)
: Next physical page address to scan

ppage_left (decimal)
: Number of physical pages left to scan in the current extent

#bufcnt (decimal)
: Number of light scan buffers used for this light scan

#look_aside (char)
: Whether look aside is needed for this light scan (`Y` = yes, `N` = no). Look asides occur when a thread needs to examine the buffer pool for existing pages to obtain the latest image of a page being light scanned.

Use the **onstat -g scn** command to display the status of a current scan, based on rows scanned on compressed tables, tables with rows that are larger than a page, and tables with VARCHAR, LVARCHAR, and NVARCHAR data. For more information, see onstat -g scn command: Print scan information.

onstat -g mem command: Print pool memory statistics

Use the **onstat -g mem** command to display the memory statistics for a pool.

If you run an SQL query that allocates memory from the PER_STMT_EXEC and PER_STMT_PREP memory duration pools, the **onstat -g mem** command displays information about the **PRP.sessionid.threadid** pool and the **EXE.sessionid.threadid** pool.

Syntax:

```
>>-onstat-- -g--mem--+-----------------------+-----------------><
                    '-pool name--session id-'
```

Session pools are named with the session number. If no argument is provided, information about all pools is displayed.

Example output

Figure 1. **onstat -g mem** command output

```
Pool Summary:

The PER_STMT_PREP memory duration

onstat -g mgm command: Print MGM resource information

Use the **onstat -g mgm** command to show resource information about Memory Grant Manager (MGM).

You can use the **onstat -g mgm** command to monitor how MGM coordinates memory use and scan threads. This command reads shared-memory structures and provides statistics that are accurate at the instant that the command runs.

Syntax:

```
>>-onstat-- -g--mgm-----------------------------------------><
```

The **onstat -g mgm** output shows a unit of memory that is called a *quantum*. The *memory quantum* represents a unit of memory, as follows:

```
memory quantum = DS_TOTAL_MEMORY / DS_MAX_QUERIES
```

The following calculation shows the memory quantum for the values that the **onstat -g mgm** output shows:

```
memory quantum = 4000 kilobytes / 31
               = 129 kilobytes
```

The database server adjusts the value of a quantum as needed when it grants memory. Therefore, the value of the quantum as shown by the **onstat -g mgm** command is not always accurate.

The *scan thread quantum* is always equal to `1`.

Example output

Figure 1. onstat -g mgm command output

```
Memory Grant Manager (MGM)
--------------------------
MAX_PDQPRIORITY:  100
DS_MAX_QUERIES:    31

Resource/Lock Cycle Prevention count:  0
```

Output description

The first portion of the output shows the values of the PDQ configuration parameters.

The second portion of the output describes MGM internal control information. It includes four groups of information. The first group is **Queries**:

Active
: Number of PDQ queries that are currently running

Ready
: Number of user queries ready to run but whose execution the database server deferred for load-control reason

Maximum
: Maximum number of queries that the database server allows to be active. Reflects current value of the DS_MAX_QUERIES configuration parameter

The next group is **Memory**:

Total
: KB of memory available for use by PDQ queries (DS_TOTAL_MEMORY specifies this value.)

Free
: KB of memory for PDQ queries not currently in use

Quantum
: Approximate number of KB of memory in a memory quantum

The next group is **Scans**:

Total
: The total number of scan threads as specified by the DS_MAX_SCANS configuration parameter

Free
: Number of scan threads currently available for decision-support queries

Quantum
: The number of scan threads in a scan-thread quantum

The last group in this portion of the output describes MGM **Load Control**:

Memory
: Number of queries that are waiting for memory

Scans
: Number of queries that are waiting for scans

Priority
: Number of queries that are waiting for queries with higher PDQ priority to run

Max Queries
: Number of queries that are waiting for a query slot

Reinit
: Number of queries that are waiting for running queries to complete after an **onmode -M** or **-Q** command

The next portion of the output, **Active Queries**, describes the MGM active and ready queues. This portion of the output shows the number of queries that are waiting at each gate:

Session
: The session ID for the session that initiated the query

Query
: Address of the internal control block that is associated with the query

Priority
: PDQ priority that is assigned to the query

Thread
: Thread that registered the query with MGM

Memory
: Memory that is currently granted to the query or memory that is reserved for the query (Unit is MGM pages, which is 8 KB.)

Scans
: Number of scan threads currently used by the query or number of scan threads that are allocated to the query

Gate
: Gate number at which query is waiting

The next portion of the output, **Free Resource**, provides statistics for MGM free resources. The numbers in this portion and in the final portion reflect statistics since system initialization or the last **onmode -Q**, **-M**, or **-S** command. This portion of the output contains the following information:

Average

Average amount of memory and number of scans

Minimum
: Minimum available memory and number of scans

The next portion of the output, **Queries**, provides statistics about MGM queries:

Average
: Average active and ready queue length

Maximum
: Maximum active and ready queue length

Total
: Total active and ready queue length

Resource/Lock Cycle Prevention count
: Number of times the system immediately activated a query to avoid a potential deadlock. (The database server can detect when some of the queries in its queue might create a deadlock situation if the queries are not run immediately.)

onstat -g nbm command: Print a block bit map

Use the **onstat -g nbm** command to display the block bit map for the nonresident segments.

Each bit of the bitmap represents a 4 KB block. If the block is used, then the bit is set to 1. If the block is free, the bit is set to 0. The bitmap is shown as a series of hexadecimal numbers. The bits, and therefore the blocks, are numbered starting at 0 so the first block is block 0, the second is block 1, and so on.

Syntax:

```
>>-onstat-- -g--nbm-------------------------------------------><
```

Example output

This example shows the bitmap for the segment of virtual memory at 0x10CC00000. The bitmap itself is at 0x10CC00290. All 1792 blocks of the segment are free except for block 0 and block 1023.
Figure 1. **onstat -g nbm** command output

```
Block bitmap for virtual segment address 0x10cc00000:
 address = 0x10cc00290, size(bits) = 1792
 used = 1, largest_free = -1
      0:8000000000000000 0000000000000000 0000000000000000 0000000000000000
    256:0000000000000000 0000000000000000 0000000000000000 0000000000000000
    512:0000000000000000 0000000000000000 0000000000000000 0000000000000000
    768:0000000000000000 0000000000000000 0000000000000000 0000000000000001
   1024:0000000000000000 0000000000000000 0000000000000000 0000000000000000
   1280:0000000000000000 0000000000000000 0000000000000000 0000000000000000
   1536:0000000000000000 0000000000000000 0000000000000000 0000000000000000
```

Output description

address
: The starting address of the bitmap.

size
: The number of bits in the bitmap. This is also the number of 4 KB blocks in the memory segment.

used
: The total number of bits in the bitmap that are set to 1. This is also the number of 4 KB blocks that are in use in the memory segment.

largest free
: If this is a value other than -1 it is the largest number of consecutive bits that are free, which is also the number of 4 KB blocks in the largest contiguous set of blocks in the memory segment.
A value of -1 means that the largest free space has not been calculated. The database server only calculates the largest free space if it tries to allocate a set of blocks starting at the *lastalloc* block but there is not enough free space. The value is set to -1 again as soon as another block is allocated in the segment.

onstat -g nsc command: Print current shared memory connection information

Use the **onstat -g nsc** command to display information about shared memory connections either for all of the current connections or for a specified connection ID.

Syntax:

```
>>-onstat-- -g--nsc--+-----------+----------------------------><
                    '-client_id-'
```

If no *client_id* is provided, information about all current shared memory connections to the database server is given. If a *client_id* is provided then this command gives more detailed information about the shared memory connection with that ID.

Example output

This is output of **onstat -g nsc** with no *client_id*. It shows that there is only one user currently connecting to the database server through shared memory. That connection has an ID of 0.

Figure 1. **onstat -g nsc** command output

```
  clientid  clientPID      state #serverbufs #clientbufs    #rdwrts
         0       6031  Connected           4           4         12
```

This example shows output from running the command using a *client_id* of 0.

Figure 2. **onstat -g nsc** command with client id output

```

```

Output description

clientid
: Server assigned ID

clientPID
: Client process ID

state
: State of connection

  Connected
  : The client has established a connection with the server.

  Con1
  : The server has successfully set up a connection with the client, but the client has not yet been notified of it.

  Waiting
  : The server is in the process of setting up a connection with the client.

  Reject
  : Client connection has been rejected by the server, normally because the server is shutting down or not yet in on-line mode.

  Closed
  : Server has closed the connection with the client. Client might not be aware of the fact yet.

  Not connected
  : Server is initializing internal structures for the connection.

  Unknown
  : Connection has been closed and the client is aware of the fact. Server is cleaning up internal structures.

#serverbufs
: Database server buffers currently allocated

#clientbufs
: Client buffers currently allocated

#rdwrts
: The total number of reads and writes performed through this connection since it was created.

The following items are only in the output if you run the **onstat -g nsc** command with a *client_id*:

needbuf
: Indicates if server is waiting for a buffer to be freed

  0

False
1
True

segid
Shared memory segment ID
semid
Semaphore ID
semnum
Semaphore number in the semaphore ID
be_semid
Backend semaphore ID
be_semnum
Backend semaphore number in the semaphore ID
be_curread
ID of backend buffer being read
be_curwrite
ID of backend buffer being written
fe_curread
ID of frontend buffer being read
fe_currwrite
ID of frontend buffer being written
be_nextread
ID of next backend buffer to be read
be_nextwrite
ID of next backend buffer to be written
fe_nextread
ID of next frontend buffer to be read
fe_nextwrite
ID of next frontend buffer to be written
readyqueue
Queue of the shared memory buffer ids

Buffers
i
Internal location key of message buffer
bufid
Message buffer ID
status
Status of message buffer
offset
Offset of memory buffer in shared memory segments
fe_addr
Frontend address of message buffer

onstat -g nss command: Print shared memory network connections status

Use the **onstat -g nss** *sessionid* command to display information about the status of the shared memory network connections.

Syntax:

```
>>-onstat-- -g--nss--+-----------+----------------------------><
                    '-sessionid-'
```

If no *sessionid* is provided, a one-line summary for each shared memory connection is listed.

Example output

Figure 1. **onstat -g nss** command output

```
clientid  clientPID   state     #serverbufs #clientbufs    #rdwrts
       1      14018  Connected         4           4        331
       0      12398  Connected         4           4        294
       2      14036  Connected         4           4         59
```

Output description

clientid (decimal)
: Server assigned value for lookups

clientPID (decimal)
: Client process ID

state (string)
: Current® state of the connection.

  - Connected
  - Con1
  - Waiting
  - Reject
  - Bedcover
  - Closed
  - Not connected
  - Unknown

#serverbufs (dec)
: Number of database server buffers currently allocated

#clientbufs (dec)

```

onstat -g opn command: Print open partitions

Use the **onstat -g opn** command to display a list of the partitions (tables and indexes), by thread ID, that are currently open in the system.

Use the ***thread_id*** option to restrict the list to a specified ID.

Syntax:

```
>>-onstat-- -g--opn--+-----------+-----------------------------><
                    '-thread_id-'
```

Output description

This information is used by Software Support. The output might change over time and depends on your product version or fix pack.

onstat -g osi: Print operating system information

Use the **onstat -g osi** command to display information on your operating system resources and parameters, including shared memory and semaphore parameters, the amount of memory currently configured on the computer, and the amount of memory that is unused.

Example Output

The **onstat -g osi** command also displays statistics on the hardware processors on your computer.

Use this command when the server is not online.

Figure 1. **onstat -g osi** Command Output

```

onstat -g pd command: Print push data session-related information

Use the **onstat -g pd** command to display information about the push data session.

Syntax:

```
>>-onstat-- -g--pd--+------------+----------------------------><
                    '-session_id-'
```

You can specify one of the following invocations.

onstat -g pd
Displays a one-line summary for each session

onstat -g pd *session_id*
Displays information for a specific session

Example output for all sessions

Figure 1. **onstat -g pd** command output

```
push-data subsystem structure at 0x4eebb028
push-data session structure at 0x4eecc028
push-data sql session id: 0 0x0
Marked as detachable session, session unique id: 2
Smartblob file descriptor: 39
Number of event conditions: 0
Number of pending event operations: 0
Number of discarded event operations: 0
Total event operations returned to client:
```

Example output for a specific session

Figure 2. **onstat -g pd** *98* command output

```
    push-data subsystem structure at 0x4eebb028
push-data session structure at 0x4eecc028
push-data sql session id: 98 0x62
Marked as detachable session, session unique id: 2
Smartblob file descriptor: 39
Number of event conditions: 1
Number of pending event operations: 0
Number of discarded event operations: 0
Total event operations returned to client: 0
```

onstat -g pd event command: Print push data event-related information

Use the **onstat -g pd** event command to display information about the push data event.

Syntax:

```
>>-onstat-- -g--pd--+------------+-- event---------------------><
                    '-session_id-'
```

You can specify one of the following invocations.

onstat -g pd event
Displays a one-line summary for each event

onstat -g pd *session_id* **event**
Displays information of an event for a specific session

Example output for all events

Figure 1. **onstat -g pd event** command output

```
IBM Informix Dynamic Server Version 14.10.F -- On-Line -- Up 00:20:13 -- 185676 Kbytes
push-data subsystem structure at 0x4eebb028
push-data session structure at 0x4eecc028
push-data sql session id: 98 0x62
Marked as detachable session, session unique id: 2
Number of event conditions: 1
    Push-data event structure at 0x4ece0028
        Full Table Name: test:informix.t1
User data:
Replicate name: pushrepl_98_1497908205_1628814989
```

Note:

- Events can only be registered on tables with logging enabled.
- Events require a primary key, a unique index, or ER key to register events on a table.
- Events cannot be registered on sysmaster pseudo tables.
- Events cannot be registered on timeseries VTI tables.
- Event condition SELECT statements cannot include large objects such as byte, text, blob, clob, or collection datatypes.

- WHERE clauses of event condition SELECT statements cannot refer to other tables or contain sub-queries.
- A read call always returns completed event documents.
- The following message is returned upon timeout from the read API:

  ```
  {ifx_isTimeout:"true"}
  ```

- The following message is returned if event documents are discarded from exceeding the max_pending_ops attribute threshold. The document contains the cumulative count of the total number of discarded event documents.

  ```
  {ifx_warn_total_skipcount:10}
  ```

- The following error message is returned with the ifx_error attribute if the input buffer size is too small, or when other fatal error conditions arise:

  ```
  {ifx_error:" Smartblob read API buffer size ## is too small, expected
  size should be atleast ##"}
  ```

- Event data will not be staged if push-data client is disconnected from the server.
- The client cannot read events for the past time. The commit_logid, commit_logpos and commit_time values in the input document cannot be set for the past time.
- The smartblob read API always returns data in JSON document format. This includes event data, warning messages, and error conditions.
- The input buffer value that is passed to the smartblob read API should be at least 1KB in size.
- When the maxrecs attribute for the session is set to more than one record, then the smartblob read API can return data for multiple events in one read call. The format of the output document format is as follows:

  ```
  { [ {document1}, {document2}]}
  ```

- When the server is restarted, the push-data client might receive duplicates of event data. Therefore, it is recommended to discard duplicate event data by saving the last read event commit_logid, and commit_logpos records, and use this commit log position to register push-data event conditions with the server.
- While registering new push-data event conditions, an internal transient cascade replicate definition is created. The replicate definition gets deleted when a session disconnects from the server. Cascading logic are added to capture changes applied by ER apply threads.
- Detached sessions will be marked as detachable session, session unique id: 2

onstat -g pfsc command: Print partition free space cache information

Use the **onstat -g pfsc** command to display information about all partition free space caches.

```
Syntax:
>>onstat -g pfsc [full] [<partnum>]
```

Example output

Figure 1. onstat -g pfsc command output

```

10000c    L-   0        0     0         0         0         0      0      0
```

Output description

tblnum
: The partition number

flg
: First position: 'L' = "Lite", 'B' = "Boosted"

  Second position: 'I' = "Boosted cache creation in progress"

npages
: Number of pages described by cache

avgfr
: Average free bytes per page in cache

nsearch
: Number of times a bin in the cache has been searched by inserts

nmiss
: Number of times a search has turned up empty

pgsrch
: Number of cached pages searched

mvbin
: Pages moved from one bin to another

For more information, see Partition Free Space Cache (PFSC) code.

onstat -g pos command: Print file values

Use the **onstat -g pos** command to display the values in the **$INFORMIXDIR/etc/.infos.DBSERVERNAME** file.

Syntax:

```
>>-onstat-- -g--pos-----------------------------------------><
```

Example output

Figure 1. **onstat -g pos** command output

```
  1   7   0 infos ver/size 3 264
  2   1   0 snum     0 52564801 44000000 4139 demo_on
  3   4   0 onconfig path /opt/IBM/informix/etc/onconfig.demo_on
  4   5   0 host informixva
  5   6   0 oninit ver IBM Informix Dynamic Server Version 11.70.UC2DE
  6   8   0 sqlhosts path /data/IBM/informix/etc/sqlhosts.demos
  7   3 -32767 sema 32769
  8   2 -32768 shm  32768 52564801 44000000 114176000 R

```

onstat -g ppd command: Print partition compression dictionary information

Use the **onstat –g ppd** command to display information about the active compression dictionaries that were created for compressed tables and table fragments or compressed B-tree indexes. You can choose to print information for a particular numbered partition or for all open partitions.

The **onstat –g ppd** command prints the same information that the **syscompdicts_full** table and the **syscompdicts** view in the **sysmaster** database display. The only difference is that the **syscompdicts_full** table and the **syscompdicts** view display information about all compression dictionaries, not just the active dictionaries.

Syntax:

```
>>-onstat-- -g--ppd--+------------------+----------------------><
                     +-partition number-+
                     '- 0---------------'
```

If you specify a partition number, **onstat -g ppd** prints the partition profile for that partition. If you specify `0`, this option prints profiles for all partitions.

Example output

Figure 1. **onstat –g ppd** Output

partnum	ColOffset	DbsNum	CrTS	CrLogID	CrLogPos	DrTS	DrLogID	DrLogPos
0x1001d5	-1	1	1393371661	4	16339024	0	0	0
0x1001d5	4	1	1393371661	4	16355408	0	0	0

Output description

partnum
: Partition number to which the compression dictionary applies

ColOffset
: The byte offset for a compressed partition blob column. `-1` means that only the row is compressed

DbsNum
: Number of the dbspace that the dictionary resides in

CrTS
: Timestamp that shows when the dictionary was created

CrLogID
: Unique ID for the logical log that was created when the dictionary was created

CrLogPos
: Position within the logical log when the dictionary was created

DrTS
: Timestamp that shows when the dictionary was purged

DrLogID
: Unique ID for the logical log that was created when the dictionary was purged

DrLogPos
: Position within the logical log when the dictionary was purged

onstat -g ppf command: Print partition profiles

Use the **onstat -g ppf *partition_number*** command to display the partition profile for the specified partition number.

Use the **onstat -g ppf** or the **onstat -g ppf 0** command to display the profiles for all partitions. If the TBLSPACE_STATS configuration parameter is set to 0, then the **onstat -g ppf** command displays: `Partition profiles disabled`.

For more information on the **onstat -g ppf** command, see the *IBM® Informix® Performance Guide*.

Syntax:

```
>>-onstat-- -g--ppf--+-partition_number-+----------------------><
                     '-0----------------'
```

Example output

Figure 1. **onstat -g ppf** command output

```
Partition profiles

```

Output description

partnum (hex)
: The partition number

lkrqs (decimal)
: The number of lock requests for a partition

lkwts (decimal)
: The number of lock waits for a partition

dlks (decimal)
: The number of deadlocks for a partition

touts(decimal)
: The number of remote deadlock timeouts for a partition

isrd (decimal)
: The number of read operations for a partition

iswrt (decimal)
: The number of write operations for a partition

isrwt (decimal)
: The number of rewrite or update operations for a partition

isdel (decimal)
: The number of delete operations for a partition

bfrd (decimal)
: The number of buffer read operations, in pages

bfwrt (decimal)
: The number of buffer write operations, in pages

seqsc (decimal)
: The number of sequential scans for a partition

rhitratio (percentage)
: The ratio of disk read operations to buffer read operations

TBLSPACE_STATS configuration parameter

onstat -g pqs command: Print operators for all SQL queries

Use the **onstat –g pqs** command to display information about the operators used in all of the SQL queries that are currently running.

You can use this command to troubleshoot an application, to find which operators are running for the query and for how long, and how many rows each operator returns. While the EXPLAIN file contains information that will give you a general sense of the query plan, the **onstat –g pqs** command displays the runtime operator information for the query and the query plan.

Syntax:

```
>>-onstat-- -g--pqs--+-----------+-----------------------------><
                     '-sessionid-'
```

You can specify one of the following invocations:

Table 1. Descriptions of each **onstat -g pqs** command invocation

Invocation	Explanation

Invocation	Explanation
onstat -g pqs	Displays a one-line summary for each session.
onstat -g pqs sessionid	Displays information for the session that you specify.

Example output

The following example shows the results when three separate SQL statements are run in different sessions. The statements are:

```
select * from syscolumns;
select * from systables a, systables b;
update t1 set rowsize = rowsize +100;
```

Figure 1. **onstat –g pqs** command output

```
Query Operators:
addr     ses-id   opname    phase   rows    time           in1          in2     stmt-type
ae50b3a  23       scan      open    0       00:00.00         0            0     SELECT
af269d0   5       nljoin    next    224717  00:01.82   af26a90      aeb4478     SELECT
af26a90   5       scan      next    472     00:00.20         0            0     SELECT
aeb4478   5       scan      next    50      00:01.63         0            0     SELECT
ad3c530  26       scan      open    0       00:00.00         0            0     UPDATE (all)
```

Output description

addr
: The address of the operator in memory. You can use this address to track which SCAN operator belongs to each JOIN operator.

ses-id
: The session ID in which the SQL statement was run.

opname
: The name of the operator.

phase
: The phase in which the operator was used. For example OPEN, NEXT, CLOSE.

rows
: The number of rows that are processed by the operator.

time
: The amount of time to process the operator. The time is displayed to the millisecond. A time of 01:20.10 is 1 minute, 20 seconds, and 10 milliseconds.

in1
: The first (outer) operator in the join.

in2
: The second (inner) operator in the join.

stmt-type
: The type of SQL statement, such as SELECT, UPDATE, DELETE.

onstat -g prc command: Print sessions using UDR or SPL routines

Use the **onstat -g prc** command to display the number of sessions that are currently using the UDR or SPL routine.

Syntax:

```
>>-onstat-- -g--prc-----------------------------------------><
```

Example output

Figure 1. onstat -g prc command output

```
UDR Cache:
    Number of lists          : 31
    PC_POOLSIZE              : 127

0    363  0    0    1          2020-05-12 10:36:32  462f2c38         stores_demo@myserver:.proc4

    Total number of udr entries : 254
    Number of entries in use    : 9
```

Output description

Number of lists

Number of lists in the UDR cache

PC_POOLSIZE
: Number of entries that can be cached at one time

list
: UDR cache hash chain ID (bucket number)

id
: Unique ID of the routine

ref
: Number of sessions that are currently accessing the UDR or SPL routine from the cache

drop
: Whether the routine is marked to be dropped

hits
: The number of times the cache entry is accessed.

last_access
: The time at which the cache entry was last accessed.

heap_ptr
: Heap address that is used to store this entry

udr_name
: The name of the UDR or SPL routine in the cache

Total number of udr entries
: Number of entries in the cache

Number of entries in use
: Number of entries that are being used

onstat -g proxy command: Print proxy distributor information

Use the **onstat -g proxy** command to display information about proxy distributors. The output of the **onstat -g proxy** command differs slightly depending on whether the command is run on a primary server or on a secondary server.

Syntax:

```
>>-onstat-- -g--proxy--+-all-------------------------------------------------+-><
                       '-proxy_id--+-----------------------------------------+-'
                                   '-proxy_transaction_id--+-----------------+-'
                                                           '-sequence_number-'
```

Invocation	Explanation
onstat -g proxy	Displays proxy distributor information
onstat -g proxy all	When run on the primary server, displays information about proxy distributors and proxy agent threads. When run on the secondary server, displays information about all sessions currently performing updates to secondary servers.
onstat -g proxy *proxy_id proxy_transaction_id sequence_number*	This option is valid only on secondary servers. Displays detailed information about the current work bring performed by a given proxy distributor. The *proxy_transaction_id* and *sequence_number* are optional parameters. When supplied, the first number is considered the *proxy_transaction_id*, and the second is interpreted as the *sequence_number*. If the supplied *proxy_transaction_id* or *sequence_number* do not exist, the command output is the same as the output for **onstat -**

Example output using the `onstat -g proxy` command on a primary server

Figure 1. **onstat -g proxy** command output (run from primary server)

```
Secondary           Proxy       Reference Transaction  Hot Row
Node                ID          Count     Count        Total
nagpur_sdc1         2619        0         2            0
nagpur_c2           2632        0         1            0
nagpur_sec          2633        0         1            0    I
```

Output description

Secondary Node
: Name of the secondary server as it is known by the primary server.

Proxy ID
: ID of the proxy distributor. Proxy IDs are unique within a high-availability cluster.

Reference Count
: Indicates the number of threads that are using the information for the current transaction. When the count becomes 0, the transaction processing is complete (either successfully or unsuccessfully).

Transaction Count
: The number of transactions currently being processed by the proxy distributor.

Hot Row Total
: Total number of hot rows ever handled by the proxy distributor.

Example output using the onstat -g proxy command on a secondary server

Figure 2. **onstat -g proxy** command output (run from secondary server)

```

```

Output description

Secondary Node
Name of the secondary server as it is known by the primary server.
Proxy ID
ID of the proxy distributor. Proxy IDs are unique within a high-availability cluster.
Reference Count
Indicates the number of threads that are using the information for the current transaction. When the count becomes 0, the transaction processing is complete (either successfully or unsuccessfully).
Transaction Count
The number of transactions currently being processed by the proxy distributor.
Hot Row Total
Total number of hot rows ever handled by the proxy distributor.
TID
ID of the proxy agent thread running on the primary server. This ID is created by the proxy distributor to handle work from the session on the secondary server.
Flags
Flags of the proxy agent thread.
Proxy ID
The ID of the proxy distributor on behalf of which the proxy agent thread (TID) is running.
Source SessID
The ID of the user's session on the secondary server.
Proxy TxnID
The number of the current transaction. These numbers are unique to the proxy distributor.
Current® Seq
The sequence number of the current operation in the current transaction.
sqlerrno
The error number of any SQL error (or 0 if no errors).
iserrno
The error number of any ISAM or RSAM error (or 0 if no errors).

Example output using the onstat -g proxy all command on a secondary server

Figure 4. **onstat -g proxy all** command output (run from secondary server)

```
Primary            Proxy      Reference Transaction  Hot Row
Node               ID         Count     Count        Total

22       2        2619     95       2        68       1        1
```

Output description

Primary Node
Name of the primary server.
Proxy ID
ID of the proxy distributor. Proxy IDs are unique within a high-availability cluster.
Reference Count
Indicates the number of threads that are using the information for the current transaction. When the count becomes 0, the transaction processing is complete (either successfully or unsuccessfully).
Transaction Count
The number of transactions currently being processed by the proxy distributor.
Hot Row Total
Total number of hot rows ever handled by the proxy distributor. A hot row is a row on a secondary server that is updated multiple times by more than one client. When a row is updated multiple times, the secondary server reads the before image from the primary server by placing an update lock on the row if the most recent update operation from a different session is not replayed on the secondary server.
Session
The session ID
Proxy ID
The ID of the proxy distributor on behalf of which the proxy agent thread (TID) is running.
Proxy TID
Transaction ID of the proxy agent thread running on the primary server. This ID is created by the proxy distributor to handle work from the secondary server session.
Proxy TxnID
The number of the current transaction. These numbers are unique to the proxy distributor.
Current Seq
The sequence number of the current operation in the current transaction.
Pending Ops
The number of operations buffered on the secondary server that have not yet been sent to the primary server.
Reference Count
Indicates the number of threads that are using the information for the current transaction. When the count becomes 0, the transaction processing is complete (either successfully or unsuccessfully).

Example output using the *proxy_id* option on a secondary server

This command returns information only on a secondary server.

Figure 5. **onstat -g proxy proxy_id** command output (run from secondary server)

```
Proxy     Reference Pending   ProxySID
TxnID     Count     Ops
1         1         1         3
2         1         1         4
```

Output description

Proxy TxnID
The number of the current transaction. These numbers are unique to the proxy distributor.
Reference Count
Indicates the number of threads that are using the information for the current transaction. When the count becomes 0, the transaction processing is complete (either successfully or unsuccessfully).
Pending Ops
The number of operations buffered on the secondary server that have not yet been sent to the primary server.
Proxy SID
Proxy session ID.

Example output using the *proxy_id proxy_transaction_id* options on a secondary server

This command returns information only on a secondary server.

Figure 6. **onstat -g proxy_id proxy_transaction_id** command output (run from secondary server)

```
Sequence  Operation rowid    Table                          sqlerrno
Number    Type              Name
28        *Update   526      stores_demo:nilesho.customer   0
```

Output description

Sequence Number
The number of the operation.
Operation Type
The type of operation to be performed. One of: Insert, Update, Delete, Other.
rowid
The row ID of the row in which to apply the operation.
Table Name
The full table name, trimmed to fit a reasonable length. Format: database.owner.tablename
sqlerrno
The error number of any SQL error (or 0 if no errors).

Example output using the *proxy_id proxy_transaction_id sequence_number* options on a secondary server

This command returns information only on a secondary server.

The output fields are the same as the output fields displayed for the **onstat -g proxy_id proxy_transaction_id** command. While the **onstat -g proxy_id proxy_transaction_id** command displays details for a transaction, the **onstat -g proxy_id proxy_transaction_id sequence_number** displays details for all transaction operations.

onstat -g qst command: Print wait options for mutex and condition queues

Use the **onstat -g qst** command to display the wait statistics for mutex queues and condition queues (queues of waiters for a mutex or a condition).

The QSTATS configuration parameter must be set to `1` to enable the collection of statistics. For more information, see QSTATS configuration parameter.

Syntax:

```
>>-onstat-- -g--qst-----------------------------------------><
```

Example output

Figure 1. **onstat -g qst** command output

```
Mutex Queue Statistics
name      nwaits    avg_time max_time avgq maxq nservs    avg_time

```

Output description

name (string)
: Name of the mutex or condition resource being waited for

nwaits (decimal)
: Number of times this resource was waited for

avg_time (decimal)
: Average time spent waiting (in microseconds)

max_time (decimal)
: Maximum time spent waiting (in microseconds)

avgq (decimal)
: Average length of the queue

maxq (decimal)
: Maximum length of the queue

nservs (decimal)
: Number of times this resource was acquired

avg_time (decimal, microsecond)
: Average time the resource was held per acquisition (in microseconds)

onstat -g rah command: Print read-ahead request statistics

Use the **onstat -g rah** command to display information about read-ahead requests.

Syntax:

```
>>-onstat-- -g--rah-------------------------------------------><
```

Example output

Figure 1. onstat -g rah command output

```
Read Ahead

# Qs                  1

```

Output description

Qs
: Number of queues for read-ahead requests

threads
: Number of read-ahead threads

Requests
: Number of read-ahead requests

Continued
: Number of times a read-ahead request continued to occur

Memory Failures
: Number of failed requests because of insufficient memory

Last Thread Add
: Date and time when the last read-ahead thread was added

Way behind
: How many page list requests were dropped because the read-ahead daemon is too far behind

Partnum
: Partition number

Buffer reads
: Number of bufferpool and disk pages that were read

Disk Reads
: Number of pages that were read from disk

Hit Ratio
: Cache hit ratio for the partition

Reqs
: Number of read ahead requests. (There are 5 instances of this output field: for data, the index, index data, log pages, and last committed rows.)

Eff
: Efficiency of the read-ahead requests. This is the ratio been the number of pages requested by read-ahead operations to the number of pages that were already cached and for which a read-ahead operations was not needed. Values are between 0 and 100. A higher number means that read ahead is beneficial. (There are 5 instances of this output field: for data, the index, index data, log pages, and last committed rows.)

Resch
: The number of requests for last committed rows that are rescheduled because the updates to a multi-piece row are not complete.

onstat -g rbm command: Print a block map of shared memory

Use the **onstat -g rbm** command to display a hexadecimal bitmap of the free and used blocks within the resident segment of shared memory.

Syntax:

```
>>-onstat-- -g--rbm-------------------------------------------><
```

Example output

Figure 1. **onstat -g rbm** command output

```
Block bitmap for resident segment address 0x44000000:
 address = 0x440003bc, size(bits) = 3035
 used = 3031, largest_free = 4

      0:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
    256:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
    512:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
    768:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
   1024:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
   1280:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
   1536:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
   1792:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff

   2304:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
   2560:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff
   2816:ffffffff ffffffff ffffffff ffffffff ffffffff ffffffff fffffe00
```

Output description

Header

address (hex)
: In-memory starting address of the used/free blocks in the segment

size (bits)
: Number of bits in the block bitmap; each bit represents one block

used (blocks)
: Used blocks in the bitmap

largest_free (blocks)
: Largest run of free blocks

Data

Bit number (decimal): data (hex)
: Bit number followed by 32 bytes of data (hex)

onstat -g rea command: Print ready threads

Use the **onstat -g rea** command to display information about the virtual processor threads whose current status is ready.

Syntax:

```
>>-onstat-- -g--rea-------------------------------------------><
```

Example output

Following is sample output from the **onstat -g rea** command. For a description of the output, see onstat -g ath command: Print information about all threads.

Figure 1. **onstat -g rea** command output

```
Ready threads:
tid      tcb      rstcb    prty     status    vp-class    name
6        536a38   406464   4        ready        3cpu     main_loop()
28       60cfe8   40a124   4        ready        1cpu     onmode_mon
33       672a20   409dc4   2        ready        3cpu     sqlexec
```

onstat -g rss command: Print RS secondary server information

Use the **onstat -g rss** commands to display information about remote standalone secondary servers.

Syntax:

```
>>-onstat-- -g--rss--+-------------+--------------------------><
                    +-verbose-----+
                    +-log---------+
                    '-server_name-'
```

The output of the **onstat -g rss** command differs slightly depending on whether the command is run on the primary server or on the RS secondary server.

Invocation	Explanation
onstat -g rss	Displays brief RS secondary server information
onstat -g rss verbose	Displays detailed RS secondary server information
onstat -g rss log	Displays log information. This command is only applicable when run on the primary server.
onstat -g rss *server_name*	Displays information about a specific RS secondary server. This command is only applicable when run on the primary server.

Example output (primary server)

Figure 1. **onstat -g rss verbose** command output, when the command is run on the primary server.

```
Local server type: Primary
Index page logging status: Enabled
Index page logging was enabled at: 2020/05/23 06:12:06
Number of RSS servers: 2

RSS Server information:

RSS Server control block: 0x64f64758
RSS server name: rahulb_3
RSS server status: Active
RSS connection status: Connected
RSS flow control:384/352
Log transmission status: Active
Next log page to send(log id,page): 6,36
Last log page acked(log id,page): 6,35
Last log page applied(log id,page): 6,35
Time of Last Acknowledgement: 2020-05-23.06:13:29
Pending Log Pages to be ACKed: 0
Approximate Log Page Backlog:0
Sequence number of next buffer to send: 231
Sequence number of last buffer acked: 230
Supports Proxy Writes: N
Total number of delay(s): 8
Time of last delay: 2020-05-23.06:13:02
```

Output description (primary server)

Local server type
: Primary or RSS (remote standalone secondary) server type

Index page logging status
: Displays whether index page logging is enabled or disabled between primary server and secondary server

Index page logging was enabled at
: Date and time that index page logging was enabled

Number of RSS servers
: Number of RS secondary servers connected to the primary server

RSS Server control block
: RS secondary server control block

RSS Server name
: Name of RS secondary server

RSS Server status
: Displays whether RS secondary server is active or not

RSS flow control
: Values, in number of logical log pages, determining when flow control is enabled or disabled, respectively.

RSS Connection status
: Connection status of RS secondary server

Log transmission status
: Displays whether log transmission is active or inactive

Next log page to send (log id, page)
: The log ID and page number of the next log page that will be sent

Last log page acked (log id, page)
: The log ID and page number of the last acknowledged log

Last log page applied (log id, page)
: The log ID and page number of the last applied log

Time of Last Acknowledgment
: The time at which the last log was acknowledged

Pending Log pages to be ACKed
: The number of logs sent but not yet acknowledged

Approximate Log Page Backlog
: The difference between the number of logs that were sent and the end of the logical log

Sequence number of next buffer to send
: The sequence number of the next buffer to be sent

Sequence number of last buffer acked
: The sequence number of the last acknowledged buffer

Supports Proxy Writes
: Displays whether the server is currently configured to allow updates to secondary servers. **Y** = supports updates to secondary servers, **N** = does not support updates to secondary servers.

Total number of delay(s)

The total number of times the flow delay occurred.

Time of last delay
: The time of last delay in flow control.

Example output with log option (primary server)

Figure 2. **onstat -g rss log** command output, when the command is run on the primary server.

```
Log Pages Snooped:
RSS Srv          From      From      Tossed
name              Cache     Disk     (LBC full)

cdr_ol_nag_1_c1    1368       1331       0
cdr_ol_nag_1_c2    1357       1342       0
cdr_ol_nag_1_c3    1356       1343       0
```

Output description with log option (primary server)

Log Pages Snooped
: Statistics for each RS secondary server

RSS Srv name
: RS secondary server name

From Cache
: From cache number

From Disk
: Log from disk

Tossed (LBC full)
: Number of log pages that were discarded as a result of the LBC becoming full

Example output (RS secondary server)

Figure 3. **onstat -g rss** command output, when the command is run on the RS secondary server.

```
Local server type: RSS
Server Status: Active
Source server name: cdr_ol_nag_1
Connection status: Connected
Last log page received(log id,page): 7,877
```

Output description (RS secondary server)

Local server type
: Primary or RSS (remote standalone secondary) server type

Server Status
: Displays whether RS secondary server is active

Source server name
: Name of the primary server

Connection status
: Connection status of RS secondary server

Last log page received (log id,page)
: Most recent log ID and page received

Example output with verbose option (RS secondary server)

Figure 4. **onstat -g rss verbose** command output, when the command is run on the RS secondary server.

```
RSS Server control block: 0x45a3fe58
Local server type: RSS
Server Status: Active
Source server name: my_server
Connection status: Connected
Last log page received(log id,page): 10,1364
Sequence number of last buffer received: 489
Sequence number of last buffer acked: 489
Delay Apply: Configured (3)
Stop Apply: Not configured.
Delay or Stop Apply control block: 0x45a40ba8
    Pending pages: 7
    Last page written: (10:1372).
    Next page to read: (10:1366).
    Delay or Stop Apply thread: Running.
```

Output description with verbose option (RS secondary server)

RSS Server control block
: The server control block.

Local server type
: The local server's type.

Server Status
: The status of the RS secondary server.

Source server name
: The name of the primary server in the RS secondary server's high-availability cluster.

Connection status
: The status of the connection between the RS secondary server and the cluster's primary server.

Last log page received (log id,page)
: The log ID and page number of the last log acknowledged by the RS secondary server.

Sequence number of last buffer received
: The sequence number of the last buffer that was received by the RS secondary server.

Sequence number of last buffer acked
: The sequence number of the last buffer acknowledged by the RS secondary server.

Delay Apply
: Whether delay apply is configured or not. The delay value, in seconds, is included in parentheses.

Stop Apply
: Whether stop apply is configured or not. The stop value, which is enclosed in parentheses, is either 1 or a Unix time.

Delay or Stop Apply control block
: The control block of the delay or the stop apply.

Pending pages
: The number of pages that are waiting to be written to the log-staging directory.

Last page written
: The log id and page number of the log that was most recently written to the log-staging directory.

Next page to read
: The log id and page number of the next log to write to the log-staging directory.

Delay or Stop Apply thread
: The status of the delay-apply or stop-apply thread.

onstat -g rwm command: Print read and write mutexes

Use the **onstat -g rwm** command to display information about read, write, and waiting mutex threads, and to list the addresses of the tickets that these threads have acquired.

Syntax:

```
>>-onstat-- -g--rwm-----------------------------------------><
```

Example output

Figure 1. **onstat -g rwm** command output

```
MUTEX   NAME     write/read/wait    tcb list
<address> <name>     first mutex
       Writer     ticket = <ticket address>   tcb=<thread address> <thread name>
       Readers    ticket = <ticket address>   tcb=<thread address> <thread name>
       Waiters    ticket = <ticket address>   tcb=<thread address> <thread name>
<address> <name>        second mutex
       Writer     ticket = <ticket address>   tcb=<thread address> <thread name>
       Readers     ticket = <ticket address>  tcb=<thread address> <thread name>
       Waiters     ticket = <ticket address>  tcb=<thread address> <thread name>
....
....
....
<address> <name>       last mutex
       Writer     ticket = <ticket address>   tcb=<thread address> <thread name>
       Readers    ticket = <ticket address>   tcb=<thread address> <thread name>
       Waiters    ticket = <ticket address>   tcb=<thread address> <thread name>
```

Output description

tcb
: List of thread addresses

Writer
: List of write threads

Readers
: List of read threads

Waiters
: List of waiting threads

ticket
: Address of ticket acquired by the thread

onstat -g sch command: Print VP information

Use the **onstat -g sch** command to display information about thread migration and the number of semaphore operations, spins, and busy waits for each virtual processor.

Syntax:

```
>>-onstat-- -g--sch---------------------------------------------><
```

Example Output

Figure 1. **onstat -g sch** command output

```
VP Scheduler Statistics:
 vp    pid       class       semops    busy waits  spins/wait

```

onstat -g scn command: Print scan information

Use the **onstat -g scn** command to display the status of a current scan and information about the scan.

If you have a long-running scan, you might want to use this command to check the progress of the scan, to determine how long the scan will take before it completes, and to view information about the scan. For tables, the **onstat -g scn** command output identifies whether a scan is a light or bufferpool scan.

Syntax:

```
>>-onstat-- -g -scn---------------------------------------------><
```

Example Output

Figure 1. **onstat -g scn** output showing table information

```
Light Scan Info
descriptor  address           next_lpage  next_ppage        ppage_left  bufcnt  look_aside

RSAM batch sequential scan info

SesID Thread Partnum  Rowid    Rows Scan'd Scan Type Lock Mode  Notes
48    68     10016e   12bb09   43146       Light     Table      Look aside,
40    47     100106   101      0           Buffpool  +Test      Must copy
```

Information about an index scan is valid when a scan is running.

Figure 2. **onstat -g scn** output showing index scan information

```
RSAM batch index scan info

SesID Thread Partnum  Scan Type Lock Mode  Notes
136   156    100197             SLock+Test
       Start Key    GT    :-2147483648:
       Stop Key     EQ    :1500:
       Current key        :170:
       Current position: buffp 0x10a4bc0c8 pagenum 2 slot 17 rowoff 4 flags 0
```

Output Description

descriptor (decimal)
: Light scan ID

address (hex)
: Memory address of the light scan descriptor

next_lpage (hex)
: Next logical page address to scan

next_ppage (hex)
: Next physical page address to scan

ppage_left (decimal)
: Number of physical pages left to scan in the current extent

bufcnt
: Number of light scan buffers used for this light scan

look_aside
: Whether look aside is needed for this light scan (`Y` = yes, `N` = no). Look asides occur when a thread needs to examine the buffer pool for existing pages to obtain the latest image of a page being light scanned.

SesID
: Session ID

Thread
: Thread ID

Partnum
: Partition number

Rowid
: Current® row ID

Rows Scan'd
: Number of rows that have been scanned

Scan Type
: For tables, either:

  - `Bufferpool`
  - `Light` (light scan)

  For indexes, either:

  - `key only`
  - No value if the scan is not a key-only scan

Lock Mode
: The type of acquired lock or no lock:

  - `Table` (table-level lock acquired)
  - `Slock` (share locks acquired)
  - `Ulock` (update locks acquired)
  - blank (no locks acquired)

  This column can also show one of the following values:

  - `+Test` (The scan tested for a conflict with the specified lock type; the lock was not acquired.)
  - `+Keep` (The acquired locks will be held until end of session instead of the end of the transaction.)

Notes
: This column can show one of the following values:

  - `Look aside`
    The light scan is performing look aside.

    The light scan reads blocks of pages directly from disk into large buffers, rather than getting each page from the buffer manager. In some cases, this process requires the light scan to check the buffer pool for the presence of each data page that it processes from one of its large buffers; this process is called *look aside*. If the page is currently in the buffer pool, the light scan will use that copy instead of the one in the light scan large buffer. If the page is not in the buffer pool, the light scan will use the copy that the light scan read from disk into its large buffer. If the light scan is performing look aside, the performance of the scan is slightly reduced.

    In many cases, the light scan can detect that it is impossible for the buffer pool to have a newer version of the page. In these situations, the light scan will not check the buffer pool, and the look aside note will be absent.

  - `Forward row lookup`
    The server is performing a light scan on a table that has rows that span pages. The light scan must access and use the buffer pool to get the remainder pieces of any rows that are not completely on the home page.

Start key
: Start key of the scan

Stop key
: End key of the scan

Current key
: The current key in the scan

Current position
: The current location of the scan in the index, for example, the page, slot, and offset

---

onstat -g sds command: Print SD secondary server information

Use the **onstat -g sds** command to display information about shared-disk secondary servers.

```
Syntax:

>>-onstat-- -g -sds -+-----------------+----------------------><
                    '-+-server_name-+-'
```

```
'-verbose-----'
```

The output of the **onstat -g sds** command differs slightly depending on whether the command is issued on the primary server or on the SD secondary server.

Invocation	Explanation
onstat -g sds	Displays brief SD secondary server information
onstat -g sds verbose	Displays detailed SD secondary server information
onstat -g sds *server_name*	Displays information about a specific SD secondary server. When *server_name* is specified, the command must be issued from the primary server.

Example output (primary server)

Figure 1. **onstat -g sds** command output when you run the command from primary server.

```
Local server type: Primary
Number of SDS servers:1

SDS server information

SDS srv      SDS srv      Connection        Last LPG sent  Supports
name         status       status            (log id,page)  Proxy Writes
C_151162     Active       Connected            554,4998    Y
```

Output description (primary server)

Local server type
: Primary or SDS (shared disk secondary) server type

Number of SDS servers
: Number of SD secondary servers connected to the primary server

SDS Srv name
: Name of SD secondary server

SDS Srv status
: Displays whether SD secondary server is active

Connection status
: Displays whether SD secondary server is connected

Last LPG sent (log id, page)
: Most recent LPG log ID and page

Supports Proxy Writes
: Displays whether the server is currently configured to allow updates to secondary servers. **Y** = supports updates to secondary servers, **N** = does not support updates to secondary servers.

Example output with verbose option (primary server)

Figure 2. **onstat -g sds *server_name*** command output when you run the command from primary server.

```
Number of SDS servers:2
Updater node alias name :server_1

SDS server control block: 0x46217640
server name: rahulb_4
server type: SDS
server status: Active
connection status: Connected
Last log page sent(log id,page):6,44
Last log page flushed(log id,page):6,44
Last log page acked (log id, page):6,44
Last LSN acked (log id,pos):6,180664
Last log page applied(log id,page): 6,44
Approximate Log Page Backlog:0
Current SDS Cycle:19
Acked SDS Cycle:19
Sequence number of next buffer to send: 447
Sequence number of last buffer acked: 444
Time of last ack:2020/05/23 06:16:28
Supports Proxy Writes: N
Time of last received message: 2020/05/23 06:16:49
Time of last alternate write: N/A
Time of last alternate read : N/A
Total number of delay(s): 11
Time of last delay: 2020/05/23 06:13:04
```

Output description with verbose option (primary server)

Number of SDS servers
: The number of SD secondary servers that share disk space with the primary server

Updater node alias name
: The name of the primary server

SDS server control block
: SD secondary server control block

server name
: The name of the server

server type
The type of server
server status
Displays whether the server is active or inactive
connection status
Status of connection between primary and secondary server
Last log page sent (log id, page)
Log ID and page of most recent log page sent
Last log page flushed (log id, page)
Log ID and page of the most recent log page flushed
Last log page acked (log id, pos))
Most recent log page acknowledged
Last LSN acked (log id, pos)
Most recent log sequence number that was acknowledged
Last log page applied(log id,page)
The log ID and page number of the last applied log
Approximate Log Page Backlog
The number of logs waiting to be sent
Current® SDS Cycle
Used internally by support to monitor coordination of the primary server with the SDS server
Acked SDS Cycle
Used internally by support to monitor coordination of the primary server with the SDS server
Sequence number of next buffer to send
Sequence number of next buffer to send
Sequence number of last buffer acked
Sequence number of next buffer acknowledged
Time of last ack
Date and time of last log acknowledgment
Supports Proxy Writes
Displays whether the server is currently configured to allow updates to secondary servers. **Y** = supports updates to secondary servers, **N** = does not support updates to secondary servers.
Time of last received message:
The timestamp of the current server's most recently received from another server.
Time of last alternate write
The timestamp of the current server's most recent write to the blobspace specified by the SDS_ALTERNATE configuration parameter.
Time of last alternate read
The timestamp of the current server's most recent read from the blobspace specified by the SDS_ALTERNATE configuration parameter.
Total number of delay(s)
The total number of times the flow delay occurred.
Time of last delay
The time of last delay in flow control.

Example output with verbose option (SD secondary server)

Figure 3. **onstat -g sds verbose** command output when you run the command from the SD secondary server.

```
SDS server control block: 0xb299880
Local server type: SDS
Server Status : Active
Source server name: my_source_server
Connection status: Connected
Last log page received(log id,page): 7,884
Next log page to read(log id,page):7,885
Last LSN acked (log id,pos):7,3621272
Sequence number of last buffer received: 0
Sequence number of last buffer acked: 0
Current paging file:/dbspaces/page_my_source_server_sdc1_
Current paging file size:2048
Old paging file:/dbspaces/page_my_source_server_sdc1_
Old paging file size:10240
```

Output description with verbose option (SD secondary server)

SDS server control block
SD secondary server control block
Local server type
Primary or SDS (shared disk secondary) server type
Server status
Displays whether SD secondary server is active
Source server name
Displays name of primary server
Connection status
Displays whether SD secondary server is connected
Last log page received (log id, page)
Most recent log page received
Next log page to read (log id,page)
Next log page in sequence to read
Last LSN acked (log id,pos)
Most recent LSN acknowledged
Sequence number of last buffer received
Sequence number of last buffer received

Sequence number of last buffer acked
: Sequence number of last buffer acknowledged

Current paging file
: Name of current paging file

Current paging file size
: Size of current paging file

Old paging file
: Name of previous paging file

Old paging file size
: Size of previous paging file

onstat -g seg command: Print shared memory segment statistics

Use the **onstat -g seg** command to show the statistics for shared memory segments.

This command shows how many segments are attached and their sizes. You can run the **onstat -g seg** command on a dump file that was created without the buffer pool.

```
Syntax:

>>-onstat-- -g--seg-------------------------------------------><
```

Example output

Figure 1. onstat -g seg command output

```
Segment Summary:
id          key         addr     size       ovhd     class blkused  blkfree
720914    52e44801   44000000 4390912    248812  R    1072     0
753683    52e44802   44430000 131072000  769136  V    22573    9427
819221    52e44803   4c130000 66027520   1       B    16120    0
851990    52e44804   50028000 83648512   1       B    20422    0
Total:    -           -       285138944 -       -    60187    9427
Virtual segment low memory reserve (bytes):4194304
Low memory reserve used 0 times and used maximum block size 0 bytes
```

Output description

id
: The ID of the shared memory segment

key
: The shared memory key that is associated with the shared memory segment ID

addr
: The address of the shared memory segment

size
: The size of the shared memory segment in bytes

ovhd
: The size of the shared memory segment control information (overhead) in bytes

class
: The class of the shared memory segment (B is for Buffferpool, R is for Resident, V is for Virtual, VX is for Virtual Extended, and M is for Message.)

blkused
: The number of blocks of used memory

blkfree
: The number of blocks of free memory

Virtual segment low memory reserve (bytes)
: The size of reserved memory for use when critical activities are needed and the server has limited free memory, specified in bytes (You specify reserved memory in the LOW_MEMORY_RESERVE configuration parameter.)

Low memory reserve used 0 times and used maximum block size 0 bytes)
: The number times that the server used the reserved memory and the maximum memory needed

Running onstat Commands on a Shared Memory Dump File

onstat -g ses command: Print session-related information

Use the **onstat -g ses** command to display information about the session.

By default, only the DBSA can view **onstat -g ses** information. However, when the UNSECURE_ONSTAT configuration parameter is set to `1`, all users can view this information.

Syntax:

```
>>-onstat-- -g--ses--+------------+--------------------------><
                     '-session_id-'
```

You can specify one of the following invocations.

onstat -g ses
Displays a one-line summary for each session

onstat -g ses *session_id*
Displays information for a specific session

Example output for all sessions

Figure 1. **onstat -g ses** *command output*

```
session                                          #RSAM    total      used       dynamic
id       user     tty       pid      hostname   threads  memory     memory     explain
24       informix -         0        -          0        12288      7936       off
23       informix -         17602    carson     1        57344      48968      off
3        informix -         0        -          0        12288      9168       off
2        informix -         0        -          0        12288      7936       off

Last 20 Sessions Terminated

Ses ID  Username  Hostname  PID    Time               Reason
46      user_1    host_1    21220  01/19/2015.15:20   session limit txn time (60s)
43      user_1    host_1    21340  01/19/2015.15:14   session limit memory (5124 KB)
61      user_1    host_1    21404  01/19/2015.15:04   session limit logspace (10242 KB)
64      user_1    host_1    21458  01/19/2015.15:02   session limit txn time (39548 KB)
```

Output description: session section

Session id
The session ID

user
The user who started the session

tty
The tty that is associated with the front end for this session

pid
The process ID associated with the front end for this session

hostname
The hostname from which this session connected

#RSAM threads
The number of RSAM thread that is allocated for this session

total memory
The amount of memory that is allocated for this session

used memory
The amount of memory that is actually used by this session

dynamic explain
Generate explain output of the SQL statements of the session (`on` or `off`)

Output description: Last 20 Sessions Terminated section

Ses ID
The session ID

Username
The user who started the session

Hostname
The hostname from which this session connected

PID
The process ID associated with the front end for this session

Time
The time at which the session was terminated.

Reason
The limit that was exceeded, followed by the limit value in parentheses.

Example output for a specific session

Figure 2. **onstat -g ses** *session_id* command output for a completed SQL statement

Txn Time(s)     120       0
```

Output description: program section

Displays the full path of the client program that is used in your session. Use the client program information to monitor or stop access to the database.

Output description: threads section

Although this section has no title, the following output displays information about threads.

tid
: The thread ID

name
: The name of the thread

rstcb
: RSAM control block

flags
: Describes the status of the thread using the following codes:
  Position 1

  B
  : Waiting on a buffer

  C
  : Waiting on a checkpoint

  G
  : Waiting on a logical-log buffer write

  L
  : Waiting on a lock

  S
  : Waiting on a mutex

  T
  : Waiting on a transaction

  X
  : Waiting on a transaction cleanup

  Y
  : Waiting on a condition

Position 2

*
: An asterisk in this position means that the thread encountered an I/O failure in the middle of a transaction

Position 3

A
: Archive thread

B
: Begin work

P
: Begin Prepare or Prepared work

X
: XA prepared

C
: Committing or committed

R
: Aborting or aborted

H
: Heuristically aborted or heuristically rolling back

Position 4

P
: Primary thread

Position 5

R
: Reading

X
: Critical section

Position 6

R
: Recovery thread

Position 7

M
: Monitor thread

D
: Daemon thread

C
: Cleaner

F
: Flusher

B
: B-tree scanner

curstk
: Current® stack size

status
: Current thread status

Output description: memory pools header section

The information is repeated for each session pool.

name
: Name of pool

class
: Class of the memory where the pool is allocated from. R is for Resident, V is for Virtual, and M is for Message

addr
: Address of the pool structure

totalsize
: Total size of the memory that is acquired by the pool (in bytes)

freesize
: Number of bytes free in the pool

#allocfrag
: Number of allocated memory fragments in the pool

#freefrag
: Number of free fragments in the pool

Output description: Memory pools section

name
: Name of a component which allocated memory from the pool

free
: Number of bytes freed

used
: Number of bytes allocated

Output description: sqscb info section

scb
: The session control block. This is the address of the main session structure in shared memory

sqscb
: SQL level control block of the session

optofc
: The current value of the **OPTOFC** environment variable or ONCONFIG configuration file setting

pdqpriority
: The current value of the **PDQPRIORITY** environment variable or ONCONFIG configuration file setting

optcompind
: The current value of the **OPTCOMPIND** environment variable or ONCONFIG configuration file setting

directives
: The current value of the **DIRECTIVES** environment variable or ONCONFIG configuration file setting

Output description: SQL section

Displays SQL information for the specified session. This section contains the same information that is output from the **onstat -g sql** command. See onstat -g sql command: Print SQL-related session information.

Output description: Last parsed SQL statement section

The Last parsed SQL statement section contains the same information that is output from the **onstat -g sql** command. See onstat -g sql command: Print SQL-related session information.

Output description: Xadatasources participated in this session section

The Xadatasources participated in this session section shows information about the XA data sources that are available during the session, their resource manager identifiers, and whether they are currently active.

Xdatasource name
: The XA data source that participated in the session

RMID
: The identifier of the resource manager for the corresponding XA data source

Active
: Whether the XA data source is still active

Output description: DRDA client info section

The **DRDA client info** section shows information about Distributed Relational Database Architecture™ (DRDA) connections to clients.

Userid
: User ID of the client user

Wrkstnname
: Name of the client workstation

Applname
: Name of the client application, for example `db2jcc_application`

Acctng
: Accounting string from the client, for example `JCC03510nemea`

Programid
: Client program identifier (not used by Informix®)

Autocommit
: Default transaction autocommit mode for Informix data sources

Packagepath
: Client package path (not used by Informix)

Output description: Session limits section

Locks
: The session's number of locks.

Memory(KB)
: The session's memory.

Temp Space(KB)
: The session's temporary table space.

Log Space(KB)
: Log space for single transactions.

Txn Time(s)
: Duration of single transactions.

Figure 3. **onstat -g ses** *session_id* command output for a running SQL statement

onstat -g shard command: Print information about the shard definition

Use the **onstat -g shard** command to display information about the sharding definition.

Syntax:

```
>>-onstat-- -g--shard-----------------------------------------><
```

Output description

The output of the **onstat -g shard** command shows the following information without field labels.

Sharding definition name
: The name of the sharding definition.

Database name
: The name of the database that contains the table or collection that is distributed across multiple shards.

Table owner name
: The owner of the table or collection that is distributed across multiple shards.

Table name
: The name of the table or collection that is distributed across multiple shards.

Shard key
: The shard key that is used for distributing rows or documents. Value can be a table column, document field, or an expression.

Sharding strategy
: The method for determining which database server a new row or document is applied on. Values can be HASH (hash algorithm), CONSISTENT HASH (consistent hash algorithm), or EXPRESSION (expression).

Sharding type
: Specifies source-server action after a row or document is replicated to a target server. Values can be DELETE, KEEP, or INFORMATIONAL.

Shard optimization
: Specifies if queries can skip shard servers that do not contain relevant data. Values can be ENABLED or NOT ENABLED.

Version column
: Specifies the column or key that is used when Enterprise Replication attempts to verify that a source row or document was not updated. The value is a column or document field.

Sharding rule
: The rule for replicating data to a specific database server.

Example: Output for a sharding definition that uses consistent hash-based sharding

For this example, you have a sharding definition that was created by the following command:

```
cdr define shardCollection collection_1 database_1:john.customers_1
   --type=delete --key=b --strategy=chash --partitions=3 --versionCol=column_3
   g_shard_server_1
   g_shard_server_2
   g_shard_server_3
```

The following example shows output when the **onstat -g shard** command is run on **g_shard_server_1**, **g_shard_server_2**, or **g_shard_server_3**.

Figure 1. **onstat -g shard** command output for a sharding definition that uses a consistent hash algorithm to distribute data across multiple shard servers.

```
collection_1 database_1:john.customers_1 key:b CONSISTENT HASH:DELETE SHARD OPTIMIZATION:NOT ENABLED
Matching for delete:column_3
   g_shard_server_1 (65542) (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 4019 and 5469)
                            or (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 5719 and 6123)
                            or (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 2113 and 2652)
   g_shard_server_2 (65543) (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 6124 and 7415)
                            or (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 5470 and 5718)
                            or (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 7416 and 7873)
   g_shard_server_3 (65544) (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 2653 and 3950)
                            or mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) >= 7874
                            or mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) < 2113
                            or (mod(abs(ifx_checksum(b::LVARCHAR, 0)), 10000) between 3951 and 4018)
```

Each shard server has three hashing partitions.

Example: Output for a sharding definition that uses hash-based sharding

For this example, you have a sharding definition that was created by the following command:

```
cdr define shardCollection collection_1 database_1:josh.customers_1
   --type=delete --key=column_2 --strategy=hash --versionCol=column_3
   g_shard_server_A
   g_shard_server_B
   g_shard_server_C
   g_shard_server_D
```

The following example shows output when the **onstat -g shard** command is run on **g_shard_server_A**, **g_shard_server_B**, **g_shard_server_C**, or **g_shard_server_D**.

Figure 2. **onstat -g shard** command output for a sharding definition that uses a hash algorithm to distribute data across multiple shard servers.

```
collection_1 database_1:josh.customers_1 key:column_2 HASH:DELETE SHARD OPTIMIZATION:ENABLED
Matching for delete:column_3
g_shard_server_A (65545) mod(ifx_checksum(column_2::LVARCHAR, 0), 4) = 0
g_shard_server_B (65546) mod(ifx_checksum(column_2::LVARCHAR, 0), 4) in (1, -1)
g_shard_server_C (65547) mod(ifx_checksum(column_2::LVARCHAR, 0), 4) in (2, -2)
g_shard_server_D (65548) mod(ifx_checksum(column_2::LVARCHAR, 0), 4) in (3, -3)
```

Example: Output for a sharding definition that uses expression-based sharding

For this example, you have a sharding definition that was created by the following command:

```
cdr define shardCollection collection_2 database_2:john.customers_2
   --type=keep --key=state --strategy=expression --versionCol=version_column
   g_shard_server_F "IN ('AL','MS','GA')"
   g_shard_server_G "IN ('TX','OK','NM')"
   g_shard_server_H "IN ('NY','NJ')"
   g_shard_server_I REMAINDER
```

The following example shows output when the **onstat -g shard** command is run on **g_shard_server_F**, **g_shard_server_G**, **g_shard_server_H**, or **g_shard_server_I**.

Figure 3. **onstat -g shard** command output for a sharding definition that uses an expression to distribute data across multiple database servers.

```
collection_2 database_2:john.customers_2 key:state EXPRESSION:KEEP SHARD OPTIMIZATION:ENABLED
Matching for delete:version_column
g_shard_server_F (65564) state IN ('AL','MS','GA')
g_shard_server_G (65565) state IN ('TX','OK','NM')
g_shard_server_H (65566) state IN ('NY','NJ')
g_shard_server_I (65567) not ((state IN ('AL','MS','GA')) or (state IN('TX','OK','NM'))
or (state IN ('NY','NJ')))
```

Example: Output for a sharding definition that uses a BSON shard key and expression-based sharding

For this example, you have a sharding definition that was created by the following command:

```
cdr define shardCollection collection_3 database_3:susan.customers_3
   -t delete -k bson_value_lvarchar(data,'age') -s expression -v version
```

```
   g_shard_server_J "BETWEEN 0 and 20"
   g_shard_server_K "BETWEEN 21 and 62"
   g_shard_server_L "BETWEEN 63 and 100"
   g_shard_server_M  REMAINDER
```

The following example shows output when the **onstat -g shard** command is run on **shard_server_J**, **shard_server_K**, **shard_server_L**, or **shard_server_M**.

Figure 4. **onstat -g shard** command output for a sharding definition that uses a BSON shard key and an expression to distribute data across multiple database servers.

```
collection_3 database_3:susan.customers_3 key:bson_value_lvarchar(data,'age')
EXPRESSION:DELETE SHARD OPTIMIZATION:ENABLED
Matching for delete:version
g_shard_server_J (65568) bson_value_lvarchar(data,'age') BETWEEN 0 and 20"
g_shard_server_K (65569) bson_value_lvarchar(data,'age') BETWEEN 21 and 62"
g_shard_server_L (65570) bson_value_lvarchar(data,'age')BETWEEN 63 and 100"
g_shard_server_M (65571) not((bson_value_lvarchar(data,'age') BETWEEN 0 and 20)
or (bson_value_lvarchar(data,'age') BETWEEN 21 and 62) or (bson_value_lvarchar
(data,'age') BETWEEN 63 and 100))
```

onstat -g smb command: Print sbspaces information

Use the **onstat -g smb** command to display detailed information about sbspaces.

Syntax:

```
>>-onstat-- -g--smb--+------------+---------------------------><
                    +-c----------+
                    +-fdd--------+
                    +-lod--------+
                    +-s----------+
                    +-e----------+
                    '-h--+-----+-'
                         +-cad-+
```

```
                +-fdd-+
                '-lod-'
```

Command	Explanation
onstat -g smb c	Lists all the chunks in the sbspace.
onstat -g smb e	Lists the entries of all smart-large-object table types.
onstat -g smb e cad	Lists the entries for the smart-large-object chunk adjunct table.
onstat -g smb e fdd	Lists the entries for the smart-large-object file descriptor table.
onstat -g smb e lod	Lists the entries in the smart-large-object header table.
onstat -g smb fdd	Lists the smart-large-object file descriptors.
onstat -g smb h	Lists the headers of all smart-large-object table types.
onstat -g smb h cad	Lists the header for the smart-large-object chunk adjunct table.
onstat -g smb h fdd	Lists the header for the smart-large-object file descriptor table.
onstat -g smb h lod	Lists the header for the smart-large-object header table.
onstat -g smb lod	Lists the header and entries in the smart-large-object header table.
onstat -g smb s	Lists the sbspace attributes (owner, name, page size, **-Df** flag settings). Fields with a value of 0 or -1 were not initialized during sbspace creation.

Example output for the onstat -g smb c command

Use the **onstat -g smb c** command to monitor the amount of free space in each sbspace chunk, and the size in pages of the user data and metadata. The **onstat -g smb c** command displays the following information for each sbspace chunk:

- Chunk number and sbspace name
- Chunk size and pathname
- Total user data pages and free user data pages
- Location and number of pages in each user-data and metadata areas

In the following example, chunk 2 of sbspace1 has 2253 original free pages (`orig fr`), 2253 user pages (`usr pgs`), and 2245 free pages (`free pg`). For the first user-data area (`Ud1`), the starting page offset is 53 and the number of pages is 1126. For the metadata area (`Md`), the starting page offset is 1179 and the number of pages is 194. For the second user data area (`Ud2`), the starting page offset is 1373 and the number of pages is 1127.

```
Chunk Summary:

sbnum 2  chunk 2
chunk:   address   flags    offset   size   orig fr   usr pgs   free pg
         303cf2a8  F------- 0        2500   2253      2253      2245
         path: /usr11/myname/sbspace1

         start pg   npages
Ud1   :  53         1126
Md    :  1179       194
Ud2   :  1373       1127
```

Output for the onstat -g smb s command

The **onstat -g smb s** command displays the storage attributes for all sbspaces in the system:

- sbspace name, flags, owner
- logging status
- average smart-large-object size
- first extent size, next extent size, and minimum extent size
- maximum I/O access time
- lock mode

For more information on the **onstat -g smb** command, see the *IBM® Informix® Performance Guide*.

onstat -g smx command: Print multiplexer group information

Use the **onstat -g smx** command to display information about the server multiplexer group for servers using SMX.

Syntax:

```
>>-onstat-- -g--smx--+-----+-------------------------------------><
                    '-ses-'
```

Command	Explanation

Command	Explanation
onstat -g smx	Displays SMX connection statistics
onstat -g smx ses	Displays SMX session statistics

Example output

Figure 1. **onstat -g smx** command output

```
SMX connection statistics:
SMX control block: 0x47d5e028

  Peer server name: lx1
  SMX connection address: 0x47d60d10
  Encryption status: Disabled  Total bytes sent: 27055
  Total bytes received: 2006989
  Total buffers sent: 782
  Total buffers received: 7090
  Total write calls: 782
  Total read calls: 7090
  Total retries for write call: 0
  Data compression level: 1
  Data sent: compressed 40760 bytes by 33%
  Data received: compressed 12579324 bytes by 84%
```

Output description

SMX control block
: SMX control block

Peer server name
: Displays the name of the peer server

SMX connection address
: Displays the address of the SMX connection

Encryption status
: Displays whether encryption is enabled or disabled

Total bytes sent
: Displays the total number of bytes sent

Total bytes received
: Displays the total number of bytes received

Total buffers sent
: Displays the total number of buffers sent

Total buffers received
: Displays the total number of buffers received

Total write calls
: Displays the total number of write calls

Total read calls
: Displays the total number of read calls

Total retries for write call
: Displays the total number of retries for write call

Data compression level
: Displays the SMX compression level as set by the SMX_COMPRESS configuration parameter

Data sent: compressed x bytes by y%
: Displays the uncompressed number of bytes and the compression ratio of the data sent

Data received: compressed x bytes by y%
: Displays the uncompressed number of bytes and the compression ratio of the data received

Example Output

Figure 2. onstat -g smx ses Output

```
SMX session statistics:
SMX control block: 0x17c69028

Peer         SMX session        client        reads         writes
name         address            type
delhi_sec      19022050    smx Clone Send            6           183
```

Output Description

SMX control block
: SMX control block

Peer name
: Displays the name of the peer server

SMX session address
: SMX session address

Client type
: Displays type of secondary server

reads
: Displays the total number of session reads

writes
Displays the total number of session writes

onstat -g spi command: Print spin locks with long spins

Use the **onstat -g spi** command to display information about spin locks with long spins.

Syntax:

```
>>-onstat-- -g--spi-----------------------------------------><
```

Many resources in the server are accessed by two or more threads. In some of these accesses (such as updating a shared value), the server must guarantee that only one thread is accessing the resource at a time. A *spin lock* is the mechanism used to provide this mutually exclusive access for some resources. With this type of lock, a thread that did not succeed in acquiring the lock on the first try (because another thread was holding it) repeatedly attempts to acquire the lock until it succeeds.

The overhead cost of a spin lock is small, and spin locks are normally used for resources that require mutual exclusion for short periods of time. However, if a spin lock becomes highly contended, the loop-and-retry mechanism can become expensive.

The **onstat -g spi** command is helpful for identifying performance bottlenecks that are caused by highly contended spin locks. This option lists spin locks with waits, those spin locks for which a thread was not successful in acquiring the lock on its first attempt and thus had to loop and re-attempt.

Example output

Figure 1. **onstat -g spi** command output

```
Spin locks with waits:

Num Waits   Num Loops    Avg Loop/Wait     Name
114         117675        1032.24          lockfr3
 87         256461        2947.83          fast mutex, lockhash[832]
  1             11          11.00          fast mutex, 1:bhash[16668]
  4          51831       12957.75          fast mutex, 1:lru-4
  1            490         490.00          fast mutex, 1:bf[994850] 0xe00002 0x14eb32000
```

Output description

Num Waits (decimal)
Total number of times a thread waited for this spin lock.
Num Loops (decimal)
Total number of attempts before a thread successfully acquired the spin lock.
Avg Loop/Wait (floating point)
Average number of attempts needed to acquire the spin lock. Computed as `Num Loops / Num Waits`.
Name (string)
Uses the following codes to name the spin lock

lockfr
The lock free list. The number after **lockfr** is the index into the lock free list array.

lockhash[]
The lock hash bucket. The field inside the brackets is the index into the lock hash bucket array.

:bhash []
The buffer hash bucket. The field before the colon is the buffer pool index; the field inside the brackets after **bhash** is the index into the buffer hash bucket array.

:lru-
The LRU latch. The field before the colon is the buffer pool index; the field after **lru-** identifies the buffer chain pairs that are being used.

:bf[]
The buffer latch. The field before the colon is the buffer pool index; the field inside the brackets after **bf** is the position of buffer in the buffer array. The next two fields are the partition number and the page header address in memory for the buffer in hex form.

onstat -g sql command: Print SQL-related session information

Use the **onstat -g sql** command to display SQL-related information about a session.

By default, only the DBSA can view **onstat -g sql** syssqltrace information. However, when the UNSECURE_ONSTAT configuration parameter is set to `1`, all users can view this information.

Syntax:

```
>>-onstat-- -g--sql--sessionid---------------------------------><
```

You can specify one of the following invocations.

Invocation
: **Explanation**

onstat -g sql
: Displays a one line summary for each session

onstat -g sql *sessionid*
: Displays SQL information for a specific session

Note: Encrypted passwords and password hint parameters in encryption functions are not shown. The following figure displays an encrypted password in the `Last parsed SQL statement` field.

Figure 1. **onstat -g sql** *command output for a completed SQL statement*

```
onstat -g sql 22

Current statement name : unlcur

Current SQL statement (8) :
  select * from systables, syscolumns, sysindexes

  QUERY_TIMEOUT setting:     0 (No Timeout)
  Clock time elapsed   : 00:00:12
```

```
Last parsed SQL statement :
  select * from systables, syscolumns, sysindexes
```

The QUERY_TIMEOUT setting and clock time are displayed only for running queries, not for DML or DDL statements or administration operations.

onstat -g spf: Print prepared statement profiles

Use the **onstat -g spf** command to display current statistics about SQL queries.

You can use the statistics to determine the cost of each statement.

Syntax:

```
>>-onstat-- -g--spf---------------------------------------------><
```

If SQL tracing is enabled, the information that is shown is a snapshot of the work that is completed by the statement and might change as the statement continues to run. For example, to monitor the growth rate of buffer reads or writes in an active statement, you can issue three **onstat -g spf** runs at 2-second intervals.

If SQL tracing is disabled, a warning message is issued: "Statistics disabled".

Example output

Figure 1. **onstat -g spf** command output

```
Statement profiles
sid   sdb      tottm  execs runtm  pdq scans sorts bfrd  pgrd  bfwrt  pgwrt  lkrqs  lkwts
35    4de84028 0.01   0     0.01   0   0     0     301   352   0      512    2998   0
25    4dc0b028 0.00   0     0.00   0   0     0     0     0     0      0      0      0
...
```

Output description

sid
: The session ID.

sdb
: The last 8 digits of the statement pointer.

tottm
: The current total run time, in seconds, of all statements.

execs
: The current number of completed statement runs. This value does not include statements that are running.

runtm
: The current run time of the statement, in seconds.

pdq
: The current parallel database queries (PDQ) priority level. The PDQ priority value can be any integer from 0 through 100. For more information, see Managing PDQ queries.

scans
: The current number of PDQ scans that are allocated.

sorts
: The current number of completed sorts.

bfrd
: The current number of buffer reads.

pgrd
: The current number of page reads.

bfwrt
: The current number of buffer writes.

pgwrt
: The current number of page writes.

lkrqs
: The current number of lock requests.

lkwts
: The current number of lock waits.

set sql tracing argument: Set global SQL tracing (SQL administration API)

onstat -g src command: Patterns in shared memory

Use the **onstat -g src** command to search for patterns in shared memory.

Syntax:

```
>>-onstat-- -g--src--pattern--mask-----------------------------><
```

Example output

The following example shows output for the **onstat -g src*pattern mask*** command where *pattern* = `0x123` and *mask* = `0xffff`.
Figure 1. **onstat -g src** command output

```
Search Summary:
addr               contents
000000000ad17a50: 01090000 00000000 00000000 00000123   ........ .......#
000000000ad7dec0: 00000001 014e3a0c 00000000 0ade0123   .....N:. .......#
```

Output description

addr (hexadecimal)
: Address in shared memory where search pattern is found

contents (hexadecimal)
: Contents of memory at given address

---

onstat -g ssc command: Print SQL statement occurrences

Use the **onstat -g ssc** command to monitor the number of times that the database server reads the SQL statement in the cache.

By default, only the DBSA can view **onstat -g ssc** syssqltrace information. However, when the UNSECURE_ONSTAT configuration parameter is set to `1`, all users can view this information.

Syntax:

```
>>-onstat-- -g--ssc--+----------+-------------------------------><
                     '-+-all--+-'
                       '-pool-'
```

The **all** option reports the *key-only* cache entries as well as the fully cached statements. If the value in the **hits** column is less than the STMT_CACHE_HITS value, that entry is a *key-only* cache entry. For more information, see memory utilization in the *IBM® Informix® Performance Guide*.

The **pool** option reports usage of all memory pools for the SQL statement cache. The output displays information on the name, class, address, and total size of the memory pools. For more information, see improving query performance in the *IBM Informix Performance Guide*.

Example output

Figure 1. **onstat -g ssc** command output

```

```

Output description - Statement Cache Summary section

#lrus
Number of least recently used queues (LRUS)
currsize
Current® cache size
maxsize
Limit on total cache memory
Poolsize
Total pool size
#hits
The number of hits before insertion. This number equals the value of the STMT_CACHE_HITS configuration parameter
nolimit
The value of the STMT_CACHE_NOLIMIT configuration parameter

Output description - Statement Cache Entries section

The Statement Cache Entries section shows the entries that are fully inserted into the cache.

lru
The index of lru queue to which the cache entry belongs
hash
Hash values of cached entry
ref_count
Number of threads referencing the statement
hits
Number of times a statement matches a statement in the cache. The match can be for a key-only or fully cached entry.
flag
Cache entry flag `-D` indicates that the statement is dropped, `-F` indicates that the statement is fully cached, and `-I` indicates that the statement is in the process of being moved to a fully cached state
heap_ptr
Address of memory heap for cache entry

onstat -g stk command: Print thread stack

Use the **onstat -g stk** *tid* command to display the stack of the thread specified by thread ID.

This option is not supported on all platforms and is not always accurate.

Syntax:

```
>>-onstat-- -g--stk -tid----------------------------------------><
```

Example output

Figure 1. **onstat -g stk** *tid* command output

```
Stack for thread: 2 adminthd
 base: 0x000000010aad5028

onstat -g stm command: Print SQL statement memory usage

Use the **onstat -g stm** command to display the memory that each prepared SQL statement uses.

By default, only the DBSA can view **onstat -g stm** syssqltrace information. However, when the UNSECURE_ONSTAT configuration parameter is set to 1, all users can view this information.

Syntax:

```
>>-onstat-- -g--stm-------------------------------------------><
```

To display the memory for only one session, specify the session ID in the **onstat -g stm** command.

Example output

Figure 1. **onstat -g stm** command output

```
session   65 ------------------------------------------------------------
 sdblock  heapsz  statement ('*' = Open cursor)
 aad8028   16544   SELECT COUNT ( * ) FROM ssc1 WHERE t1_char = ?
 AND t1_key = ? AND t1_short = ?
```

Output description

sdblock
: Address of the statement descriptor block

heapsz
: Size of the statement memory heap

statement
: Query text

onstat -g stq command: Print queue information

Use the **onstat -g stq** command to display information about the queue.

Syntax:

```
>>-onstat-- -g--stq--session-----------------------------------><
```

To view queue information for a particular session specify the *session* option. Omit the *session* option to view queue information for all sessions.

Example output

Figure 1. **onstat -g stq** command output

```
Stream Queue: (session 25 cnt 4)  0:db12400  1:db18400  2:dcf0400  3:dcf6400
 Full Queue:  (cnt 2  waiters 0)  0:0  1:db12400
 Empty Queue: (cnt 0  waiters 0)
```

Output description

session
: Session id

cnt
: Number of stream queue buffers

waiters
: Number of threads waiting for the stream queue buffer

onstat -g sts command: Print stack usage for each thread

Use the **onstat -g sts** command to display information about the maximum and current stack use for each thread.

Syntax:

```
>>-onstat-- -g--sts-------------------------------------------><
```

Example output

Figure 1. **onstat -g sts** command output

```
Stack usage:

onstat -g sym command: Print symbol table information for the oninit utility

Use the **onstat -g sym** command to display symbol table information for the **oninit** utility.

Syntax:

```
>>-onstat-- -g--sym-----------------------------------------><
```

Example output

Figure 1. **onstat -g sym** command output
The following example shows the first few lines from the output:

```
Table for oninit has 23378 entries
    Initial value for -base-: 0x0
        0x3451e0 _start
        0x345300 .ld_int
        0x345348 .ld_llong
        0x3453dc .ld_float
        0x345428 .ld_double
        0x3454c4 .st_int
        0x3454fc .st_llong
        0x34556c .st_float
        0x3455c0 .st_double
        0x34565c .st_float_foreff
        0x345694 .st_double_foreff
        0x345718 main
        0x34c2ac get_cfgfile
        0x34c2fc is_server_alias
```

Output description

The **onstat -g sym** command displays the relative in-memory address and name of symbols (functions and variables) in the **oninit** utility.

onstat -g top command: Print top consumers of resources

Use the **onstat -g top** command to display information about top consumers of various resources such as CPU time, I/O operations, and memory growth.

You can specify the maximum number of consumers to display, along with the sample time interval. The onstat -g top command may be followed by three optional numeric arguments:

```
Syntax:

>>onstat -g top [<keyword pair>] [<max consumers> [<interval> [<repeats>]]]
```

Onstat -g top can take an optional pair of keyword arguments:

- **Top Threads**
  - onstat -g top thread cpu: Threads currently using the most CPU time.
  - onstat -g top thread drd: Threads currently performing the most disk reads.
  - onstat -g top thread bfr: Threads currently performing the most buffer reads.
  - onstat -g top thread bfw: Threads currently performing the most buffer writes.
  - onstat -g top thread plg: Threads currently performing the most physical logging.
  - onstat -g top thread llg: Threads currently performing the most logical logging.
- **Top Sessions**
  - onstat -g top session cpu: Sessions currently using the most CPU time.
  - onstat -g top session drd: Sessions currently performing the most disk reads.
  - onstat -g top session bfr: Sessions currently performing the most buffer reads.
  - onstat -g top session bfw: : Sessions currently performing the most buffer writes.
  - onstat -g top session plg: Sessions currently performing the most physical logging.
  - onstat -g top session llg: Sessions currently performing the most logical logging.
- **Top Chunks**
  - onstat -g top chunk ios: Chunks currently performing the most reads and writes.
  - onstat -g top chunk art: Chunks with the highest average read time.
  - onstat -g top chunk awt: Chunks with the highest average write time.
- **Top Spaces**
  - onstat -g top space ios: Spaces currently performing the most reads and writes.
  - onstat -g top space art: Spaces with the highest average read time.
  - onstat -g top space awt: Spaces with the highest average write time.
- **Top Virtual Memory Pools**
  - onstat -g top mempool gro: Memory pools currently growing the fastest.
- **Top Session Memory**
  - onstat -g top sessmem gro: Sessions currently allocating the most memory.
- **Top Partitions**
  - onstat -g top partition drd: Partitions currently performing the most disk reads.
- **Top Tables**
  - onstat -g top table drd: Tables currently performing the most disk reads.

Example

Figure 1. **onstat -g top** command examples

```
Top 3 spaces for average write times
onstat -g top space awt 3
top 10 tables for disk reads over a 1 minute interval
onstat -g top partition drd 10 60
Top 15 threads for CPU time, sampling every 20 seconds, and repeating 5 times
 onstat -g top thread cpu 15 20 5
Memory pools that are growing, updating every 30 seconds, repeating indefinitely
onstat -g top mempool gro 0 30 0
The least active session in terms of buffer reads, repeating 10 times, with 5 seconds between each update
onstat -g top session BFR 1 5 10
```

Note: To reverse the order of the consumer list, capitalize the second keyword. For example, the following command will display the top *least* active chunks:

```
onstat -g top chunk IOS
```

onstat -g tpf command: Print thread profiles

Use the **onstat -g tpf** command to display thread profiles.

```
Syntax:

>>-onstat-- -g--tpf--tid----------------------------------------><
```

Specify the *tid* thread ID to print the profile for a specific thread. Set *tid* to 0 to display the profiles for all of the threads.

Example output

Figure 1. **onstat -g tpf** command output

```
onstat -g tpf 945

Thread profiles
tid lkreqs lkw dl to lgrs isrd iswr isrw isdl isct isrb lx bfr bfw lsus lsmx seq
945 1969   0   0  0  6181 1782 2069 13   0    0    0    0  16183 7348 743580 0    6
```

Output description

tid
: Thread ID

lkreqs
: Lock requests

lkw
: Lock waits

dl
: Deadlocks

to
: Remote deadlock timeout

lgrs
: Log records

isrd
: Number of reads

iswr
: Number of writes

isrw
: Number of rewrites

isdl
: Number of deletes

isct
: Number of commits

isrb
: Number of rollbacks

lx
: Long transactions

bfr
: Buffer reads

bfw
: Buffer writes

lsus
: Log space currently used

lsmx
: Max log space used

seq
: Sequence scans

onstat -g ufr command: Print memory pool fragments

Use the **onstat -g ufr** command to display a list of the fragments that are currently in use in the specified memory pool.

This command requires an additional argument to specify either a pool name or session ID whose memory pool information is to be displayed. Each session is allocated a memory pool with the same name as the session ID. Use the **onstat -g mem** command to identify the pool name and the **onstat -g ses** command to identify the session ID.

Syntax:

```
>>-onstat-- -g--ufr--+-pool name-+-----------------------------><
                     '-sessionid-'
```

Memory pools are broken into fragments for various uses. With the **onstat -g ufr** command it is possible to see a list of these fragments showing their respective sizes in bytes and the type of information they contain. The information provided is generally used by Technical Support to assist in the analysis of a reported problem.

Example output for a specified pool name

Figure 1. **onstat -g ufr global** command output for a specified pool name

```
Memory usage for pool name global:
size       memid
1736       overhead
23544      mcbmsg
72         messages
33112      osenv
25432      rsam
88         shmblklist
5170664    net
```

Example output for a specified session ID

The following example shows the output for session ID 6.

Figure 2. **onstat -g ufr** command output for a specified session ID

```
Memory usage for pool name 6:
size       memid
3256       overhead
```

```
144         scb

Output description

size (decimal)
: Size, in bytes, of the pool fragment.

memid (string)
: Name of the pool fragment.

onstat -g vpcache command: Print CPU virtual processor and tenant virtual processor private memory cache statistics

Run the **onstat -g vpcache** command to display statistics about CPU virtual processor and tenant virtual processor private memory caches.

Syntax:

```
>>-onstat-- -g--vpcache-----------------------------------------><
```

Example output

The output for each CPU or tenant virtual processor has the same format. The following example shows the output for one CPU virtual processor.

Figure 1. **onstat -g vpcache** command output

```
CPU virtual processor memory block cache statistics - 4096 byte blocks

Number of 4096 byte memory blocks requested for each CPU virtual processor:262144
CPU virtual processor memory block cache mode : Dynamic

vpid    pid          Blocks held  Hit percentage   Free cache

Output description

vpid
: The ID of the virtual processor

pid
: The process ID for the virtual processor that is assigned by the operating system

Blocks held
: The number of 4096 byte blocks that are available in the private memory cache

Hit percentage
: The percentage of time that a block was available when requested

Free cache
: The percentage of time that blocks were freed for reuse without being drained

Current VP total allocations from cache
: The number of times a block or group of blocks was taken from the cache

Total frees
: The number of times a block or group of blocks was added to the cache

size
: The size of the memory blocks, in 4096-byte blocks

cur blks
: The current number of 4096-byte blocks that are allocated (a multiple of `size`)

tgt blks
: The target number of blocks for the cache entry before the cache is drained

alloc
: The number of times a requestor received a block of this size

miss
: The number of times a block was requested but none were available

free
: The number of times a memory block was placed into the cache

drain
: The number of times an aged block was forced out to make room for another block

draintime
: The last time the bin of memory blocks was drained

onstat -g wai command: Print wait queue thread list

Use the **onstat -g wai** command to display a list of the threads in the system that are currently in the wait queue and not currently executing. The output is sorted by thread ID.

Syntax:

```
>>-onstat-- -g--wai-----------------------------------------><
```

Example output

Figure 1. **onstat -g wai** command output

```
Waiting threads:

Output description

tid (decimal)
: Thread ID

tcb (hex)
: In-memory address of the thread control block

rstcb (hex)
: In-memory address of the RSAM thread control block

prty (decimal)
: Thread priority. Higher numbers represent higher priorities

status (string)
: Current® status of the thread

vp- (decimal and string)
: Virtual processor integer ID of the VP on which the thread last ran, concatenated with the name of the VP upon which the thread runs

name (string)
: Name of the thread

onstat -g wmx command: Print all mutexes with waiters

Use the **onstat -g wmx** command to display all of the mutexes with waiters.

Syntax:

```
>>-onstat-- -g--wmx-----------------------------------------><
```

Example output

Figure 1. **onstat -g wmx** command output

```
Mutexes with waiters:
mid      addr              name              holder   lkcnt  waiter   waittime
134825   7000002043a9148   free_lock         11009    0      200      22921
                                                             11010    22918
```

Output description

mid
: Internal mutex identifier

addr
: Address of locked mutex

name
: Name of the mutex

holder
: Thread ID of the thread that is holding the mutex
: 0 = The read/write mutex is held in shared mode

lkcnt
: For a read/write mutex, the current number of threads that are locking the mutex in shared mode. For a relockable mutex, the number of times the mutex was locked or relocked by the thread that is holding the mutex.

waiter
: List of IDs of the threads that are waiting for this mutex

waittime
: Amount of time in seconds that the thread is waiting

onstat -g wst command: Print wait statistics for threads

Use the **onstat -g wst** command to show the wait statistics for the threads within the system.

The WSTATS configuration parameter must be set to `1` to enable wait statistics collection. For more information, see WSTATS configuration parameter .

Syntax:

```
>>-onstat-- -g--wst-----------------------------------------><
```

Example output

```

```

Output description

name (string)
: Thread name

tid (decimal)
: Thread ID

state (string)
: State the thread waited in for this line of output. A single thread can have multiple lines of output if it waited in more than one state. Values that can appear in the `state` field include:

- `chkpt cond`: The thread waited for a checkpoint condition.
- `cp mutex`: The thread waited for checkpoint mutex to become available.
- `deadlock mutex`: The thread waited for a deadlock mutex to become available.
- `empty Q`: The thread waited for an empty buffer on a queue.
- `fork`: The thread waited for a child thread to run.
- `full Q`: The thread waited for a full buffer on a queue.
- `IO Idle`: The I/O thread was idle.
- `IO Wait`: The thread yielded while it waited for I/O completion.
- `join wait`: The thread waited for another thread to exit.
- `lock mutex`: The thread waited for lock mutex to become available.
- `lockfree mutex`: The thread waited for a lock-free mutex to become available.
- `logflush`: Logical log flushing occurred.
- `log mutex`: The thread waited for logical log mutex to become available.
- `logcopy cond`: The thread waited for logical log copy condition.
- `logio cond`: The thread waited for a logical log condition.
- `lrus mutex`: The thread waited for a buffer LRU mutex to become available.
- `misc`: The thread waited for a miscellaneous reason.
- `other cond`: The thread waited for an internal condition.
- `other mutex`: The thread waited for an internal system mutex to become available.
- `other yield`: The thread yielded for an internal reason.
- `OS read`: The thread waited for an operating system read call to complete.
- `OS write`: The thread waited for an operating system write call to complete.
- `ready`: The thread was ready to run.
- `run`: The thread ran.
- `sort io`: The thread waited for sort I/O completion.
- `vp mem sync`: The thread waited for synchronization of virtual processor memory.
- `yield bufwait`: The thread yielded while it waited for a buffer to become available.
- `yield 0`: The thread yielded with an immediate timeout.
- `yield time`: The thread yielded with a timeout.
- `yield forever`: The thread yielded and stays that way until it wakes up.

n (decimal)
: Number of times the thread waited in this state

avg(us) (floating point)
: Average user time the thread spent waiting in this state per wait occurrence. Time is in microseconds; an `s` after the value indicates user time in seconds.

max(us) (floating point)
: Maximum user time the thread spent waiting in this state for a single wait occurrence. Time is in microseconds; an `s` after the value indicates user time in seconds.

WSTATS configuration parameter

onstat -G command: Print TP/XA transaction information

Use the **onstat -G** command to display information about global transactions generated through the TP/XA library.

Syntax:

```
>>-onstat-- -G-------------------------------------------------><
```

Example output

Figure 1. **onstat -G** command output

```
Global Transaction Identifiers
address    flags  isol    timeout  fID       gtl  bql  data      dbpartnum
```

```
45cb0318   -LH-G  COMMIT  0        4478019   2    2    30323032  100163
```

For a tightly coupled transaction, all branches share the same transaction address shown in the address column.

Output description

address
: Transaction address

flags
: **Flag codes for position 1 (current transaction state):**

  A
  : User thread attached to the transaction

  S
  : TP/XA suspended transaction

  C
  : TP/XA waiting for rollback

  Flag codes for position 2 (transaction mode):

  T
  : Tightly-coupled mode (MTS)

  L
  : Loosely-coupled mode (default mode)

  Flag codes for position 3 (transaction stage):

  B
  : Begin work

  P
  : Distributed query prepared for commit

  X
  : TP/XA prepared for commit

  C
  : Committing or committed

  R
  : Rolling back or rolled back

  H
  : Heuristically rolling back or rolled back

  Flag code for position 4:

  X
  : XA data source global transaction

  Flag codes for position 5 (type of transaction):

  G
  : Global transaction

  C
  : Distributed query coordinator

  S
  : Distributed query subordinate

  B
  : Both distributed query coordinator and subordinate

  M
  : Redirected global transaction

isol
: Transaction isolation level

timeout
: Transaction lock timeout

fID
: Format ID

gtl
: Global transaction ID length

bql
: Branch qualifier length

data
: Transaction-specific data

dbpartnum
: Database identifier of where the transaction starts

onstat -h command: Print buffer header hash chain information

Use the **onstat -h** command to display information about the buffer header hash chains (sometimes called "hash buckets") that are used to access pages in each buffer pool.

Syntax:

```
>>-onstat-- -h-------------------------------------------------><
```

Example output

The output is displayed in the form of a numeric histogram of chain lengths, with summary information for each buffer pool. All numeric values in the output are decimal. Shorter hash chains enable requested buffers to be located more quickly by the server, because on average it will need to check fewer buffer headers on a target chain to find the target buffer.

The page size of the buffer pool in bytes is shown as a header to the output for each buffer pool. The histogram and summary information are then presented for that buffer pool.

Figure 1. **onstat -h** command output

```
Buffer pool page size: 2048

buffer hash chain length histogram
   # of chains          of len
          3423               0
          4546               1
           223               2
          8192   total chains
          4992   hashed buffs
          5000    total buffs

Buffer pool page size: 4096

buffer hash chain length histogram
   # of chains          of len
           707               0
           315               1
             2               2
          1024   total chains
           319   hashed buffs
          1000    total buffs
```

Output description

Histogram Information on Hash Chains

The histogram information has a row for each buffer hash chain length that presently exists in the system. Each row has two columns:

of chains
: Number of hash chains of the given length

of len
: Length of these chains

Summary Information Per Buffer Pool

total chains
: Number of hash chains that exist for this buffer pool

hashed buffs
: Number of buffer headers currently hashed into the hash chains for this buffer pool

total buffs
: Total number of buffers in this buffer pool

onstat -i command: Initiate interactive mode

Use the **onstat -i** command to put the **onstat** utility in the interactive mode.

Syntax:

```
>>-onstat-- -i--+-------------+--------------------------------><
               +-r--seconds--+
               '-rz--seconds-'
```

In interactive mode, you can enter multiple **onstat** options per session, but only one at a time. An **onstat** prompt appears and allows you to enter an option.

Important: In interactive mode, do not precede the option with a dash.

Additional options

Two additional options, **onstat r *seconds*** and **onstat rz *seconds***, are available in interactive mode. The **onstat r *seconds*** option is similar to the current **onstat -r *seconds*** option, which repeatedly generates a display. If an administrator executes **onstat r *seconds*** at the interactive-mode prompt, the prompt changes to reflect the specified interval in seconds and reappears, waiting for the next command. In the following example, the display generated by the next command repeats every three seconds:

```
onstat> r 3
onstat[3]>
```

The **onstat rz *seconds*** option enables you to repeat the next command as specified and set all profile counters to 0 between each execution.

Terminating interactive mode or repeating sequence

To terminate the interactive mode, press `CTRL-d`.

To terminate a repeating sequence, press `CTRL-c`.

onstat -j command: Provide onpload status information

Use the **onstat -j** command to provide information about the status of an **onpload** job.

The **onstat -j** command provides an interactive mode that is analogous to the **onstat -i** command.

Syntax:

```
>>-onstat-- -j-------------------------------------------------><
```

When **onpload** starts, it writes a series of messages to **stdout** or to a log file. The following lines show a typical **onpload** log file:

```
Mon Jul 23 16:11:30 2010

SHMBASE         0x4400000
CLIENTNUM       0x49010000
Session ID 1

Load Database   -> cnv001
Load Table      -> cnv001a
Load File       -> testrec.dat
Record Mapping  -> cnv001a

Database Load Completed -- Processed 50 Records
Records Inserted-> 50
Detected Errors--> 0
Engine Rejected--> 0

Mon Jul 23 16:11:37 2010
```

Output description

The two lines that start with SHMBASE and CLIENTNUM provide the information that you need to locate shared memory for an instance of **onpload**. The **oninit** process has similar values stored in the $ONCONFIG file. When you use the **onstat** utility to gather information about the **oninit** process, the **onstat** utility uses information from $INFORMIXDIR/etc/$ONCONFIG file to locate shared memory. When you use **onstat** to gather information about **onpload**, you must give the **onstat** utility the name of a file that contains SHMBASE and CLIENTNUM information.

Typically the file that contains the SHMBASE and CLIENTNUM information is the log file. For example, if the **onpload** log file is **/tmp/cnv001a.log**, you can enter the following command:

```
onstat -j /tmp/cnv001a.log
```

The previous command causes the **onstat** utility to attach to **onpload** shared memory and to enter interactive mode. You can then enter a question mark (?) or any other pseudo request to see a usage message displayed. An example follows:

```
onstat> ?
Interactive Mode: One command per line, and - are optional.
    -rz    repeat option every n seconds (default: 5) and
           zero profile counts
  MT COMMANDS:
    all    Print all MT information
    ath    Print all threads
    wai    Print waiting threads
    act    Print active threads
    rea    Print ready threads
    sle    Print all sleeping threads
    spi    print spin locks with long spins
    sch    print VP scheduler statistics
    lmx    Print all locked mutexes
    wmx    Print all mutexes with waiters
    con    Print conditions with waiters
    stk <tid>   Dump the stack of a specified thread
    glo    Print MT global information
    mem <pool name|session id>   print pool statistics.
    seg    Print memory segment statistics.
    rbm    print block map for resident segment
    nbm    print block map for non-resident segments
```

```
    afr <pool name|session id> Print allocated poolfragments.
    ffr <pool name|session id> Print free pool fragments.
    ufr <pool name|session id> Print pool usage breakdown
    iov   Print disk IO statistics by vp
    iof   Print disk IO statistics by chunk/file
    ioq   Print disk IO statistics by queue
    iog   Print AIO global information
    iob   Print big buffer usage by IO VP
    sts   Print max and current stack sizes
    qst   print queue statistics
    wst   print thread wait statistics
    jal   Print all Pload information
    jct   Print Pload control table
    jpa   Print Pload program arguments
    jta   Print Pload thread array
    jmq   Print Pload message queues, jms for summary only
onstat>
```

Most of the options are the same as those that you use to gather information about Informix®, with the following exceptions:

```
jal   Print all Pload information
jct   Print Pload control table
jpa   Print Pload program arguments
jta   Print Pload thread array
jmq   Print Pload message queues, jms for summary only
```

These options apply only to **onpload**. You can use the **onstat -j** command to check the status of a thread, locate the VP and its PID, and then attach a debugger to a particular thread. The options for the **onstat** utility that do not apply to **onpload** are not available (for example, **onstat -g ses**).

onstat -k command: Print active lock information

Use the **onstat -k** command to print information about active locks, including the address of the lock in the lock table.

Syntax:

```
>>-onstat-- -k-------------------------------------------------><
```

Example output

The maximum number of locks available is specified by the value of the LOCKS configuration parameter in the onconfig file.

Figure 1. onstat -k command output

```
Locks
address  wtlist   owner    lklist   type     tblsnum  rowid    key#/bsiz
a095f78  0        a4d9e68  0        HDR+S    100002   203         0
 1 active, 2000 total, 2048 hash buckets, 0 lock table overflows
```

In the following output, the number 2 in the last row shows an Enterprise Replication pseudo lock:

```
Locks
address  wtlist    owner    lklist   type    tblsnum  rowid    key#/bsiz
a1993e8  0         5c2f03d0 a19be30     S         2   1c05a            0
```

Output description

address
: Is the address of the lock in the lock table
If a user thread is waiting for this lock, the address of the lock shows in the **wait** field of the **onstat -u** (users) output.

wtlist
: Is the first entry in the list of user threads that is waiting for the lock, if there is one

owner
: Is the shared-memory address of the thread that is holding the lock
This address corresponds to the address in the **address** field of **onstat -u** (users) output. When the **owner** value is displayed in parentheses, it represents the shared memory address of a transaction structure. This scenario is possible only when a lock is allocated for a global transaction. This address corresponds to the address field of the output for **onstat -G**.

lklist
: Is the next lock in a linked list of locks that are held by the owner listed

type
: Uses the following codes to indicate the type of lock:

  HDR
  : Header

  B
  : Bytes

  S
  : Shared

  X

Exclusive

I
: Intent

U
: Update

IX
: Intent-exclusive

IS
: Intent-shared

SIX
: Shared, intent-exclusive

tblsnum
: Is the tblspace number of the locked resource. If the number is less than 10000, it indicates Enterprise Replication pseudo locks.

rowid
: Is the row identification number
The rowid provides the following lock information:

- If the rowid equals zero, the lock is a table lock.
- If the rowid ends in two zeros, the lock is a page lock.
- If the rowid is six digits or fewer and does not end in zero, the lock is probably a row lock.
- If the rowid is more than six digits, the lock is probably an index key-value lock.

key#/bsiz
: Is the index key number, or the number of bytes locked for a VARCHAR lock
If this field contains 'K-' followed by a value, it is a key lock. The value identifies which index is being locked. For example, K-1 indicates a lock on the first index that is defined for the table.

LOCKS configuration parameter

onstat -l command: Print physical and logical log information

Use the **onstat -l** command to display information about the physical logs, logical logs, and temporary logical logs.

Syntax:

```
>>-onstat-- -l-----------------------------------------------><
```

Example Output

Figure 1. **onstat -l** command output

```
Physical Logging
Buffer bufused  bufsize  numpages numwrits pages/io

 8 active, 8 total
```

Output description for the physical log files

The first section of the display describes the physical-log configuration:

buffer
: Is the number of the physical-log buffer

bufused
: Is the number of pages of the physical-log buffer that are used

bufsize
: Is the size of each physical-log buffer in pages

numpages
: Is the number of pages written to the physical log

numwrits
Is the number of writes to disk
pages/io
Is calculated as `numpages/numwrits`
This value indicates how effectively physical-log writes are being buffered.

phybegin
Is the physical page number of the beginning of the log
physize
Is the size of the physical log in pages
phypos
Is the current position in the log where the next log-record write is to occur
phyused
Is the number of pages used in the log
%used
Is the percent of pages used

The second section of the **onstat -l** command output describes the logical-log configuration:

buffer
Is the number of the logical-log buffer
bufused
Is the number of pages used in the logical-log buffer
bufsize
Is the size of each logical-log buffer in pages
numrecs
Is the number of records written
numpages
Is the number of pages written
numwrits
Is the number of writes to the logical log
recs/pages
Is calculated as `numrecs/numpages`
You cannot affect this value. Different types of operations generate different types (and sizes) of records.

pages/io
is calculated as `numpages/numwrits`
You can affect this value by changing the size of the logical-log buffer (specified as LOGBUFF in the ONCONFIG file) or by changing the logging mode of the database (from buffered to unbuffered, or vice versa).

The following fields are repeated for each logical-log file:

address
Is the address of the log-file descriptor
number
Is logid number for the logical-log file
The logid numbers might be out of sequence because either the database server or administrator can insert a log file in-line.

flags
Provides the status of each log as follows:

A
Newly added (and ready to use)
B
Backed up
C
Current® logical-log file
D
Marked for deletion
To drop the log file and free its space for reuse, you must perform a level-0 backup of all storage spaces

F
Free, available for use
L
The most recent checkpoint record
U
Used

uniqid
Is the unique ID number of the log
begin
Is the beginning page of the log file
size
Is the size of the log in pages
used
Is the number of pages used
%used
Is the percent of pages used
active
Is the number of active logical logs
total
Is the total number of logical logs

Output description for temporary logical log files

The database server uses *temporary logical logs* during a warm restore because the permanent logs are not available then. The following fields are repeated for each temporary logical-log file:

address
Is the address of the log-file descriptor
number
Is logid number for the logical-log file
flags
Provides the status of each log as follows:

B
Backed up
C
Current logical-log file
F
Free, available for use
U
Used

uniqid
Is the unique ID number of the log
begin
Is the beginning page of the log file
size
Is the size of the log in pages
used
Is the number of pages used
%used
Is the percent of pages used
active
Is the number of active temporary logical logs

LOGBUFF configuration parameter
PHYSBUFF configuration parameter

onstat -L command: Print the number of free locks

Use the **onstat -L** command to print the number of free locks on a lock-free list.

```
Syntax:

>>-onstat-- -L-------------------------------------------------><
```

Example output

Figure 1. **onstat -L** output

```
num   list head     available locks
0     10a143b70     19996
1     101010101     200
3     020202020     300
```

Output description

num
The list number
list head
The starting address of the list
available locks
The number of locks on this list

onstat -m command: Print recent system message log information

Use the **onstat -m** command to display the 20 most recent lines of the system message log.

You can use the **onstat -m** command option with the database server in any mode, including offline.

Syntax:

```
>>-onstat-- -m-----------------------------------------------><
```

Example output

Output from this command lists the full pathname of the message log file and the 20 file entries. A date-and-time header separates the entries for each day. A time stamp prefaces single entries within each day. The name of the message log is specified as MSGPATH in the **ONCONFIG** file.

Figure 1. **onstat -m** command output

```
Message Log File: /work/11.50/dbspaces/star3.log
11:26:33  Checkpoint Completed:  duration was 0 seconds.
11:26:33  Checkpoint loguniq 1, logpos 0x23c408, timestamp: 0x2cc2 Interval: 9
```

onstat -o command: Output shared memory contents to a file

Use the **onstat -o** command to write the contents of shared memory to a specified file for later analysis. If you do not specify an output file, a file named **onstat.out** is created in the current directory.

Syntax:

```
>>-onstat-- -o--+---------+----+---------+---------------------><
               +-nobuffs-+    '-outfile-'
               '-full----'
```

Use the **nobuffs** option to exclude the buffer pool in the resident segment of shared memory from the output file. This results in a smaller output file.

Use the **full** option to create an output file that is the same size as the shared memory segments for the IBM® Informix® instance. You must have enough room in the file system to handle the output.

If you do not specify either the **nobuffs** or the **full** option, the output is controlled by the database server DUMPSHMEM configuration parameter setting:

- If DUMPSHMEM is set to 0 or to 1, **onstat -o** command writes a full shared-memory dump file.
- If DUMPSHMEM is set to 2, **onstat -o** command writes a **nobuffs** shared-memory dump file that excludes the buffer pool in the resident segment.

By running additional **onstat** commands against the file, you can gather information from a previously saved shared memory dump. The *outfile* that you create with the **onstat -o** command is the *infile* that you can use as a source file to run the additional **onstat** commands. For more information, see Running onstat Commands on a Shared Memory Dump File.

DUMPSHMEM configuration parameter (UNIX)

onstat -p command: Print profile counts

Use the **onstat -p** command to display information about profile counts either since you started the database server or since you ran the **onstat -z** command.

Syntax:

```
>>-onstat-- -p-----------------------------------------------><
```

Example output

Figure 1. **onstat -p** command output

```

```

Output description

The first portion of the output describes reads and writes.

Reads and writes are tabulated in three categories: from disk, from buffers, and number of pages (read or written).

The first **%cached** field is a measure of the number of reads from buffers compared to reads from disk. The second **%cached** field is a measure of the number of writes to buffers compared to writes to disk.

The database server buffers the information and writes the information to the disk in pages. For this reason, the number of disk writes displayed as `dskwrits` is usually less than the number of writes that an individual user runs:

dskreads
The number of actual reads from disk
pagreads
The number of pages read
bufreads
Is the number of reads from shared memory
%cached
The percent of reads cached in the buffer pool.
If `bufreads` exceeds the maximum integer (or long) value, its internal representation becomes a negative number, but the value appears as `0.0`.

dskwrits
The actual number of physical writes to disk
This number includes the writes for the physical and logical logs reported in **onstat -l** .

pagwrits
The number of pages written
bufwrits
The number of writes to shared memory
%cached
The percent of writes cached in the buffer pool.

The next portion of the **-p** display tabulates the number of times different ISAM calls were executed. The calls occur at the lowest level of operation and do not necessarily correspond one-to-one with SQL statement execution. A single query might generate multiple ISAM calls. These statistics are gathered across the database server and cannot be used to monitor activity on a single database unless only one database is active or only one database exists:

isamtot
The total number of calls
open
Increments when a tblspace is opened
start
Increments the pointer within an index
read
Increments when the read function is called
write
Increments with each write call
rewrite
Increments when an update occurs
delete
Increments when a row is deleted
commit
Increments each time that an **iscommit()** call is made
No one-to-one correspondence exists between this value and the number of explicit COMMIT WORK statements that are executed.

rollbk
Increments when a transaction is rolled back

The next portion of the **onstat -p** command output displays information about generic pages. The Generic Page Manager provides an API for Informix® to manage nonstandard pages in the database server buffer pool. The following table describes the Generic Page Manager fields in the **onstat -p** command output.

gp_read
The number of generic page reads
gp_write
The number of generic page writes
gp_rewrt
The number of generic page updates
gp_del
The number of generic page deletes
gp_alloc
The number of generic page allocations
gp_free
The number of generic pages freed and returned to tblspaces
gp_curs
The number of cursors used against generic pages

The next portion of the **onstat -p** command output displays the number of times that a resource was requested when none was available:

ovlock
Number of times that sessions attempted to exceed the maximum number of locks

For more information, see “LOCKS” on page 1-56.

ovuserthread
The number of times that a user attempted to exceed the maximum number of user threads
ovbuff
The number of times that the database server did not find a free shared-memory buffer
When no buffers are free, the database server writes a dirty buffer to disk and then tries to find a free buffer.

usercpu
Is the total user CPU time that all user threads use, expressed in seconds
This entry is updated every 15 seconds.

syscpu
The total system CPU time that all user threads use, expressed in seconds
This entry is updated every 15 seconds.

numckpts
The number of checkpoints since the boot time
flushes
The number of times that the buffer pool wasflushed to the disk

The next portion of the **onstat -p** command output contains miscellaneous information, as follows:

bufwaits
Increments each time that a user thread must wait for a buffer
lokwaits
Increments each time that a user thread must wait for a lock
lockreqs
Increments each time that a lock is requested
deadlks
Increments each time that a potential deadlock is detected and prevented
dltouts
Increments each time that the distributed deadlock time-out value is exceeded while a user thread is waiting for a lock
ckpwaits
Is the number of checkpoint waits
compress
Increments each time that a data page is compressed
seqscans
Increments for each sequential scan

*
The last portion of the **onstat -p** command output contains the following information:

ixda-RA
The count of read-aheads that go from index leaves to data pages
idx-RA
The count of read-aheads that traverse index leaves
da-RA
The count of data-path-only scans
logrec-RA
The log records that the database server read ahead
RA-pgsused
The number of pages used that the database server read ahead
lchwaits
Stores the number of times that a thread was required to wait for a shared-memory latch
Many latch waits typically results from a high volume of processing activity in which the database server is logging most of the transactions.

DEADLOCK_TIMEOUT configuration parameter

onstat -P command: Print partition information

Use the **onstat -P** command to display the partition number and the pages in the buffer pool for all of the partitions.

```
Syntax:

>>-onstat-- -P-------------------------------------------------><
```

For information about running **onstat -P** on a dump file created without the buffer pool, see Running onstat Commands on a Shared Memory Dump File.

Example output

Figure 1. **onstat -P** command output

```
Buffer pool page size: 2048
partnum  total    btree    data     other    dirty
0        36       1        8        27       0
```

```

Output description

Buffer pool page size
: The size, in bytes, of the buffer pool pages.

partnum
: The partition number.

total
: The total number of partitions.

btree
: The number of B-tree pages in the partition.

data
: The number of data pages in the partition.

other
: The number of other pages in the partition.

dirty
: The number of dirty pages in the partition.

---

onstat -r command: Repeatedly print selected statistics

Use the **onstat -r** command to repeatedly print the statistics for other options specified in the command at specified intervals.

Syntax:

```
>>-onstat-- -r--+-------------------------+--------------------><
               +-seconds--other_options-+
               '-other_options----------'
```

Use the **onstat -r *seconds other_options*** command to specify the seconds to repeat the other option.

Use **onstat -r *other_options*** command to have the option repeat every five seconds, which allows the other options to be concatenated with the **-r** option, as in this example: `onstat -rFh`.

The **onstat -r** command can be used in both command mode and interactive mode, and can be useful for repeating command output to monitor system resource utilization.

Example output running the onstat -r command every five seconds

Figure 1. command output

```
onstat -r

IBM Informix Dynamic Server Version 11.70.F       -- On-Line -- Up 20:05:25 -- 1067288 Kbytes

IBM Informix Dynamic Server Version 11.70.F       -- On-Line -- Up 20:05:30 -- 1067288 Kbytes

IBM Informix Dynamic Server Version 11.70.F       -- On-Line -- Up 20:05:35 -- 1067288 Kbytes
```

Example output running the onstat -r command every ten seconds

Figure 2. command output

```
onstat -r 10

IBM Informix Dynamic Server Version 11.50.F       -- On-Line -- Up 20:06:58 -- 1067288 Kbytes
```

```
IBM Informix Dynamic Server Version 11.50.F       -- On-Line -- Up 20:07:08 -- 1067288 Kbytes

IBM Informix Dynamic Server Version 11.50.F       -- On-Line -- Up 20:07:18 -- 1067288 Kbytes
```

Example output running the onstat -r every one second, with the -h option

```

onstat -R command: Print LRU, FLRU, and MLRU queue information

Use the **onstat -R** command to display detailed information about the LRU queues, FLRU queues, and MLRU queues. For each queue, the **onstat -R** command displays the number of buffers in the queue and the number and percentage of buffers that have been modified.

For an in-depth discussion of the three types of queues, see LRU queues in the shared-memory chapter of the *IBM® Informix® Administrator's Guide*.

Syntax:

```
>>-onstat-- -R-------------------------------------------------><
```

Example output

Figure 1. **onstat -R** command output

```
        Buffer pool page size: 2048
        8 buffer LRU queue pairs              priority levels
    # f/m   pair total     % of    length       LOW      HIGH
     0 f         375     100.0%      375        375         0
     1 m                   0.0%        0          0         0
     2 f         375     100.0%      375        375         0
     3 m                   0.0%        0          0         0
     4 f         375     100.0%      375        375         0
     5 m                   0.0%        0          0         0
     6 F         375     100.0%      375        375         0

     6 f         250     100.0%      250        250         0
     7 m                   0.0%        0          0         0
    0 dirty, 1000 queued, 1000 total, 1024 hash buckets, 8192 buffer size
    start clean at  60.000% (of pair total) dirty, or 150 buffs dirty, stop at
      50.000%
```

Output description

Buffer pool page size
: Is the page size of the buffer pool in bytes

#
: Shows the queue number
Each LRU queue is composed of two subqueues: an FLRU queue and a MLRU queue. (For a definition of FLRU and MLRU queues, see LRU queues in the shared-memory chapter of the *IBM Informix Administrator's Guide*.) Thus, queues 0 and 1 belong to the first LRU queue, queues 2 and 3 belong to the second LRU queue, and so on.

f/m
: Identifies queue type
This field has four possible values:

  f
  : Free LRU queue
  In this context, free means not modified. Although nearly all the buffers in an LRU queue are available for use, the database server attempts to use buffers from the FLRU queue rather than the MLRU queue. (A modified buffer must be written to disk before the database server can use the buffer.)

  F
  : Free LRU with fewest elements
  The database server uses this estimate to determine where to put unmodified (free) buffers next.

  m
  : MLRU queue

  M
  : MLRU queue that a flusher is cleaning

length
: Tracks the length of the queue measured in buffers

% of
: Shows the percent of LRU queue that this subqueue composes
For example, suppose that an LRU queue has 50 buffers, with 30 of those buffers in the MLRU queue and 20 in the FLRU queue. The **% of** column would list percents of 60.00 and 40.00, respectively.

pair total
: Provides the total number of buffers in this LRU queue

priority levels

Displays the priority levels: `LOW, MED_LOW, MED_HIGH, HIGH`

The **onstat -R** command also lists the priority levels.

Summary information follows the individual LRU queue information. You can interpret the summary information as follows:

dirty
Is the total number of buffers that have been modified in all LRU queues
queued
Is the total number of buffers in LRU queues
total
Is the total number of buffers
hash buckets
Is the number of hash buckets
buffer size
Is the size of each buffer
start clean
Is the value specified in the **lru_max_dirty** field of the BUFFERPOOL configuration parameter
stop at
Is the value specified in the **lru_min_dirty** field of the BUFFERPOOL configuration parameter
priority downgrades
Is the number of LRU queues downgraded to a lower priority.
priority upgrades
Is the number of LRU queues upgraded to a higher priority.

---

onstat -s command: Print latch information

Use the **onstat -s** command to display general latch information, including the resource that the latch controls.

Syntax:

```
>>-onstat-- -s-------------------------------------------------><
```

Example output

Figure 1. **onstat -s** command output

```
IBM Informix Dynamic Server Version 14.10.F         -- On-Line (CKPT REQ)
-- Up 00:19:21 -- 167608 Kbytes
Blocked:CKPT

Latches with lock or userthread set
name     address           lock wait userthread
physlog  4410d5a8          0    0    45a616b8
```

Output description

name
Identifies the resource that the latch controls with the following abbreviations:

archive
Storage-space backup
bf
Buffers
bh
Hash buffers
chunks
Chunk table
ckpt
Checkpoints
dbspace
Dbspace table
flushctl
Page-flusher control
flushr
Page cleaners
locks
Lock table
loglog
Logical log
LRU
LRU queues
physb1
First physical-log buffer
physb2

Second physical-log buffer

physlog
: Physical log

pt
: Tblspace tblspace

tblsps
: Tblspace table

users
: User table

address
: Is the address of the latch
This address appears in the **onstat -u** (users) command output wait field if a thread is waiting for the latch.

lock
: Indicates if the latch is locked and set
The codes that indicate the lock status (`1` or `0`) are computer dependent.

wait
: Is the shared-memory address of the user thread that is waiting for a latch, or is blank when no user threads are waiting

userthread
: Is the shared-memory address of the user thread that holds the latch
This address corresponds to the value in the **tcb** column of the **onstat -g ath** output. You can compare this address with the user addresses in the **onstat -u** output to obtain the user-process identification number.

---

onstat -t and onstat -T commands: Print tblspace information

Use the **onstat -t** command to display tblspace information for active tblspaces. Use the **onstat -T** command to display tblspace information for all tblspaces.

The **onstat -t** command also lists the number of active tblspaces and the total number of tblspaces.

Syntax:

```
>>-onstat--+- -t-+-----------------------------------------><
           '- -T-'
```

Example output

Figure 1. **onstat -t** command output

```
Tblspaces
 n address  flgs ucnt tblnum   physaddr         npages nused  npdata nrows  nextns
62 a40dc70  0    1    100001   1:14             250    250    0      0      1
195 ac843e0  0    1    1000df   1:236             16     9      4      53     2
 2 active, 221 total
```

Output description

n
: Is a counter of open tblspaces

address
: Is the address of the tblspace in the shared-memory tblspace table

flgs
: Uses the following flag bits to describe the flag:

0x00000002
: Flush the partition info at the next checkpoint.

0x00000004
: Drop partition is in progress.

0x00000008
: Partition is a pseudo partition (sysmaster).

0x00000020
: ALTER TABLE is in progress.

0x00000040
: Partition has been dropped.

0x00000800
: Partition is the system temp table.

0x00001000
: Partition is the user temp table.

0x00008000
: Online index create or drop in progress.

0x00400000
: A single user access to the partition is requested.

0x00800000
: Drop partition is completed.

0x40000000
Flush the partition info. The partition flush can be delayed until later in the checkpoint process.

ucnt
Is the usage count, which indicates the number of user threads currently accessing the tblspace

tblnum
Is the tblspace number expressed as a hexadecimal value
The integer equivalent appears as the **partnum** value in the **systables** system catalog table.

physaddr
Is the physical address (on disk) of the tblspace

npages
Is the number of pages allocated to the tblspace

nused
Is the number of used pages in the tblspace

npdata
Is the number of data pages used

nrows
Is the number of data rows used

nextns
Is the number of noncontiguous extents allocated
This number is not the same as the number of times that a next extent has been allocated.

onstat -u command: Print user activity profile

Use the **onstat -u** command to display a profile of user activity.

Syntax:

```
>>-onstat-- -u-------------------------------------------------><
```

Example output

Figure 1. **onstat -u** command output

```
Userthreads
address  flags   sessid   user     tty      wait     tout locks nreads   nwrites
a4d8018  ---P--D 1        informix -        0        0    0     58       4595

a4d9858  ---P--D 7        informix -        0        0    0     0        0
a4d9e68  Y--P--- 21       niraj    -        a65e5a8  0    1     0        0
 6 active, 128 total, 7 maximum concurrent
```

Output description

The **-u** option displays the following output for each user thread.

address
The shared-memory address of the user thread in the user table.
Compare this address with the addresses displayed in the output from the **-s** option (latches); the output from the **-b**, **-B**, and **-X** options (buffers); and the output from the **-k** option (locks) to learn what resources this thread is holding or waiting for.

flags
Provides the status of the session.
The flag codes for position 1:

B
Waiting for a buffer
C
Waiting for a checkpoint
G
Waiting for a write of the logical-log buffer
L
Waiting for a lock
S
Waiting for mutex
T
Waiting for a transaction
Y
Waiting for condition
X
Waiting for a transaction cleanup (rollback)
DEFUNCT
The thread has incurred a serious assertion failure, and has been suspended to allow other threads to continue their work.

The flag code for position 2:

*
: Transaction active during an I/O failure

The flag code for position 3:

A
: A dbspace backup thread

For other values that appear here, see the third position of flag codes for the **-x** option.

The flag code for position 4:

P
: Primary thread for a session

The flag codes for position 5:

R
: Reading

X
: Thread in critical section

The flag codes for position 6:

R
: Thread used in recovery (for example, physical or logical recovery)

-
: Thread not used in recovery

The flag codes for position 7:

B
: A B-tree cleaner thread

C
: Terminated user thread waiting for cleanup

D
: A daemon thread

F
: A page-cleaner thread

sessid
: The session identification number.
During operations such as parallel sorting and parallel index building, a session might have many user threads associated with it. For this reason, the session ID identifies each unique session.

user
: The user login name, which is derived from the operating system

tty
: The name of the standard error (stderr) file that the user is using, which is derived from the operating system.
This field is blank on Windows.

wait
: If the user thread is waiting for a specific latch, lock, mutex, or condition, this field displays the address of the resource. Use this address to map to information provided in the output from the **-s** (latch) option or the **-k** (lock) option. If the wait is for a persistent condition, run a **grep** for the address in the output from the **onstat -a** command.

tout
: The number of seconds left in the current wait
If the value is `0`, the user thread is not waiting for a latch or lock. If the value is `-1`, the user thread is in an indefinite wait.

locks
: The number of locks that the user thread is holding
The **-k** output should include a listing for each lock held.)

nreads
: The number of disk reads that the user thread has executed

nwrites
: The number of write calls that the user thread has executed
All write calls are writes to the shared-memory buffer cache.

The last line of the **onstat -u** command output displays the maximum number of concurrent user threads that were allocated since you initialized the database server. For example, the last line of a sample **onstat -u** command output is as follows:

```
4 active, 128 total, 17 maximum concurrent
```

The last part of the line, `17 maximum concurrent`, indicates that the maximum number of user threads that were running concurrently since you initialized the database server is 17.

The output also indicates the number of active users and the maximum number of users allowed.

onstat -x command: Print database server transaction information

Use the **onstat -x** command to display transaction information on the database server.

Syntax:

```
>>-onstat-- -x-------------------------------------------------><
```

The transaction information is required only in the following situations:

- X/Open environment
- Database server participation in distributed queries
- Database server uses the Microsoft Transaction Server (MTS) transaction manager

Example output

Figure 1. **onstat -x** command output

```
Transactions

```

Output description

You can interpret output from the **onstat -x** command as follows:

address
: The shared-memory address of the transaction structure

flags
: The flag codes for position 1 (current transaction state):

  A
  : User thread attached to the transaction

  S
  : TP/XA suspended transaction

  C
  : TP/XA waiting for rollback

  The flag codes for position 2 (transaction mode):

  T
  : Tightly-coupled mode (MTS)

  L
  : Loosely-coupled mode (default mode)

  The flag codes for position 3 (transaction stage):

  B
  : Begin work

  P
  : Distributed query prepared for commit

  X
  : TP/XA prepared for commit

  C
  : Committing or committed

  R
  : Rolling back or rolled back

  H

Heuristically rolling back or rolled back

The flag code for position 4:

X
XA transaction

The flag codes for position 5 (type of transaction):

G
Global transaction
C
Distributed query coordinator
S
Distributed query subordinate
B
Both distributed query coordinator and subordinate
M
Redirected global transaction

userthread
The thread that owns the transaction (**rstcb** address)
locks
The number of locks that the transaction holds
begin logpos
The position within the log when the BEGIN WORK record was logged.
current logpos
The current log position of the most recent record that the transaction is wrote too (As a transaction rolls back, the current log position will actually wind back until it gets to the beginning log position. When the beginning log position is reached, the rollback is complete.)
isol
The isolation level.
est. rb time
The estimated time the server needs to rollback the transaction. As a transaction goes forward, this time increases. If a transaction rolls back, the time decreases as the transaction unwinds.
retrys
Are the attempts to start a recovery thread for the distributed query
coord
The name of the transaction coordinator when the subordinate is executing the transaction
This field tells you which database server is coordinating the two-phase commit.

The last line of the **onstat -x** command output indicates that `8` is the maximum number of concurrent transactions since you initialized the database server.

```
8 active, 128 total, 8 maximum concurrent
```

- Determine the position of a logical-log record
  Use the **onstat -x** command to determine the position of a logical-log record.
- Determine the mode of a global transaction
  The **onstat -x** command is useful for determining whether a global transaction is executing in loosely-coupled or tightly-coupled mode.

Determine the position of a logical-log record

Use the **onstat -x** command to determine the position of a logical-log record.

The **curlog** and **logposit** fields provide the exact position of a logical-log record. If a transaction is not rolling back, **curlog** and **logposit** describe the position of the most recently written log record. When a transaction is rolling back, these fields describe the position of the most recently “undone” log record. As the transaction rolls back, the **curlog** and **logposit** values decrease. In a long transaction, the rate at which the **logposit** and **beginlg** values converge can help you estimate how much longer the rollback is going to take.

For an **onstat -x** command example, see monitoring a global transaction in the chapter on multiphase commit protocols in the *IBM® Informix® Administrator's Guide*.

Determine the mode of a global transaction

The **onstat -x** command is useful for determining whether a global transaction is executing in loosely-coupled or tightly-coupled mode.

The second position of the flags column in the output from the **onstat -x** command displays the flags for global transactions. The `T` flag indicates tightly-coupled mode and the `L` flag indicates loosely-coupled mode.

- *Loosely-coupled mode* means that the different database servers coordinate transactions but do not share locks. Each branch in a global transaction has a separate transaction XID. The records from all branches display as separate transactions in the logical log.
- *Tightly-coupled mode* means that the different database servers coordinate transactions and share resources such as locking and logging. In a global transaction, all branches that access the same database share the same transaction XID. Log records for branches with the same XID appear under the same session ID. MTS uses tightly-coupled mode.

onstat -X command: Print thread information

Use the **onstat -X** command to obtain precise information about the threads that are waiting for buffers.

For each buffer in use, the **onstat -X** command displays general buffer information that is also available with either the **onstat -b** or **onstat -B** commands. For more information, refer to the **onstat -b** command in onstat -b command: Print buffer information for buffers in use.

Syntax:

```
>>-onstat-- -X-------------------------------------------------><
```

Example output

Figure 1. **onstat -X** command output

```
        Buffers (Access)
    address  owner    flags pagenum          memaddr  nslots pgflgs scount   waiter
        Buffer pool page size: 2048
     0 modified, 3000 total, 4096 hash buckets, 2048 buffer size
        Buffer pool page size: 8192
     0 modified, 1000 total, 1024 hash buckets, 8192 buffer size
```

Output description

The **onstat -X** command has a **waiter** field to list all user threads that are waiting for the buffer, whereas the **onstat -b** and **onstat -B** commands contain a **waitlist** field that displays the address of the first user thread that is waiting for the buffer. The maximum number of shared buffers is specified in the **buffers** field in the BUFFERPOOL configuration parameter in the ONCONFIG file.

Buffer pool page size
: The size of the buffer pool pages in bytes

address
: The address of the buffer header in the buffer table

flags
: Flags identifying the current status of the buffer page:

  0x01
  : Modified Data

  0x02
  : Data

  0x04
  : LRU

  0x08
  : Error

  0x10
  : Shared lock

  0x20
  : LRU AIO write in progress

  0x40
  : Chunk write in progress

  0x80
  : Exclusive lock

  0x100
  : Cleaner assigned to LRU

  0x200
  : Buffer should avoid bf_check calls

  0x400
  : Do log flush before writing page

  0x800
  : Buffer has been 'buff' -checked

  0x8000
  : Buffer has been pinned

pagenum
: The physical page number on the disk

memaddr
: The buffer memory address

nslots
: The number of slot-table entries in the page
  This field indicates the number of rows (or portions of a row) that are stored on the page.

pgflgs
: Uses the following values, alone or in combination, to describe the page type:

  1
  : Data page

  2

Tblspace page

4
Free-list page

8
Chunk free-list page

9
Remainder data page

b
Partition resident blobpage

c
Blobspace resident blobpage

d
Blob chunk free-list bit page

e
Blob chunk blob map page

10
B-tree node page

20
B-tree root-node page

40
B-tree branch-node page

80
B-tree leaf-node page

100
Logical-log page

200
Last page of logical log

400
Sync page of logical log

800
Physical log

1000
Reserved root page

2000
No physical log required

8000
B-tree leaf with default flags

scount
Displays the number of threads that are waiting for the buffer

waiter
Lists the addresses of all user threads that are waiting for the buffer

onstat -z command: Clear statistics

Use the **onstat -z** command to clear database server statistics, including statistics that relate to Enterprise Replication, and set the profile counts to 0.

If you use the **onstat -z** command to reset and monitor the count of some fields, be aware that profile counts are incremented for all activity that occurs in any database that the database server manages. Any user can reset the profile counts and thus interfere with monitoring that another user is conducting.

Syntax:

```
>>-onstat-- -z-------------------------------------------------><
```

Return codes on exiting the onstat utility

The **onstat** utility displays a set of return codes when you exit the utility.

Example

The following lines are an example of the messages and return codes that are displayed when you exit the **onstat** utility:

```
GLS failures: -1
Failed to attach shared memory: -1
Failed to attach shared memory when running 'onstat -': 255
All other errors detected by onstat: 1
No errors detected by onstat: 0
Administration mode: 7
```

Return code values

The following table lists the database server mode that corresponds to the return codes that are displayed when you exit the **onstat** utility.

Value	Explanation
-1	GLS locale initialization failed or failed to attach to shared memory
0	Initialization mode
1	Quiescent mode
2	Recovery mode
3	Backup mode
4	Shutdown mode
5	Online mode
6	Abort mode
7	User mode
255	Off-Line mode

SQL Administration API

- SQL Administration API Functions
  These topics describe the SQL administration API **admin()** and **task()** functions.

SQL Administration API Functions

These topics describe the SQL administration API **admin()** and **task()** functions.

- SQL Administration API Overview
  Use the SQL administration API to remotely administer through SQL statements.
- SQL administration API portal: Arguments by privilege groups
  You can view a list of **admin()** and **task()** function arguments, which are sorted by privilege groups, with links to information about the arguments.
- add bufferpool argument: Add a buffer pool (SQL administration API)
  Use the add bufferpool argument with the **admin()** or **task()** function to create a buffer pool.
- add chunk argument: Add a new chunk (SQL administration API)
  Use the add chunk argument with the **admin()** or **task()** function to add a chunk to a dbspace or blobspace.
- add log argument: Add a new logical log (SQL administration API)
  Use the add log argument with the **admin()** or **task()** function to add a logical log to a dbspace.
- add memory argument: Increase shared memory (SQL administration API)
  Use the add memory argument with the **admin()** or **task()** function to add to the virtual portion of shared memory.
- add mirror argument: Add a mirror chunk (SQL administration API)
  Use the add mirror argument with the **admin()** or **task()** function to add a mirror chunk to a dbspace.
- alter chunk argument: Change chunk status to online or offline (SQL administration API)
  Use the alter chunk argument with the **admin()** or **task()** function to bring a chunk online or take a chunk offline in a dbspace, blobspace, or sbspace.
- alter logmode argument: Change the database logging mode (SQL administration API)
  Use the alter logmode argument with the **admin()** or **task()** function to change the database logging mode to ANSI, buffered, non-logging, or unbuffered.
- alter plog argument: Change the physical log (SQL administration API)
  Use the alter plog argument with the **admin()** or **task()** function to change the location and size of the physical log.
- archive fake argument: Perform an unrecorded backup (SQL administration API)
  Use the archive fake argument with the **admin()** or **task()** function to perform a backup operation to clone the data in a server without creating a persistent backup that could be used to perform a restore.
- autolocate database add argument: Add a dbspace to the dbspace list (SQL administration API)
  Use the autolocate database add argument with the **admin()** or **task()** function to add a dbspace to the list of available dbspaces for the automatic location and fragmentation of tables for the specified database.
- autolocate database anywhere argument: Add all dbspaces to the dbspace list (SQL administration API)
  Use the autolocate database anywhere argument with the **admin()** or **task()** function to specify that the database server can use any non-critical dbspace for the automatic location and fragmentation of tables for the specified database.
- autolocate database argument: Specify dbspaces for automatic location and fragmentation (SQL administration API)
  Use the autolocate database argument with the **admin()** or **task()** function to specify the list of available dbspaces for the automatic location and fragmentation of tables for the specified database.
- autolocate database off argument: Disable automatic fragmentation for a database (SQL administration API)
  Use the autolocate database off argument with the **admin()** or **task()** function to disable the automatic location and fragmentation of tables for a specified database.
- autolocate database remove argument: Remove a dbspace from the dbspace list (SQL administration API)
  Use the autolocate database remove argument with the **admin()** or **task()** function to remove a dbspace from the list of available dbspaces into which the database server can automatically locate and fragment tables for the specified database.
- cdr argument: Administer Enterprise Replication (SQL administration API)
  Use the cdr argument with the **admin()** or **task()** function to administer Enterprise Replication.

- cdr add trustedhost argument: Add trusted hosts (SQL administration API)
  Use the cdr add trustedhost argument with the **admin()** or **task()** function to add trusted-host relationships for database servers in a high-availability cluster or Enterprise Replication domain. For a database to participate in a high-availability cluster or Enterprise Replication domain, its host must be listed in the trusted-host files of the other high-availability or replication servers.
- cdr autoconfig serv argument: Autoconfigure connectivity and replication (SQL administration API)
  The cdr autoconfig serv argument with the **admin()** or **task()** function can autoconfigure connectivity for servers in a high-availability cluster or Enterprise Replication domain, and can autoconfigure replication.
- cdr list trustedhost argument: List trusted hosts (SQL administration API)
  Use the cdr list trustedhost argument with the **admin()** or **task()** function to list trusted-host information from the file that is specified by the database server's REMOTE_SERVER_CFG configuration parameter.
- cdr remove trustedhost argument: Remove trusted hosts (SQL administration API)
  Use the cdr remove trustedhost argument with the **admin()** or **task()** function to remove entries from a database server's trusted-host file.
- check data argument: Check data consistency (SQL administration API)
  Use the check data argument with the **admin()** or **task()** function to check or repair all pages in the specified partition for consistency.
- check extents argument: Check extent consistency (SQL administration API)
  Use the check extents argument with the **admin()** or **task()** function to verify that the extents on disk correspond to the current control information.
- check partition argument: Check partition consistency (SQL administration API)
  Use the check partition argument with the **admin()** or **task()** function to print tblspace information for a table or fragment.
- checkpoint argument: Force a checkpoint (SQL administration API)
  Use the checkpoint argument with the **admin()** or **task()** function to force a checkpoint.
- clean sbspace argument: Release unreferenced smart large objects (SQL administration API)
  Use the clean sbspace argument with the **admin()** or **task()** function to release any unreferenced BLOB or CLOB objects from the sbspace.
- create blobspace argument: Create a blobspace (SQL administration API)
  Use the create blobspace argument with the **admin()** or **task()** function to create a blobspace.
- create blobspace from storagepool argument: Create a blobspace from the storage pool (SQL administration API)
  Use the create blobspace from storagepool argument with the **admin()** or **task()** function to create a blobspace from an entry from the storage pool.
- create chunk argument: Create a chunk (SQL administration API)
  Use the create chunk argument with the **admin()** or **task()** function to create a chunk in a dbspace or in a blobspace.
- create chunk from storagepool argument: Create a chunk from the storage pool (SQL administration API)
  Use the create chunk from storagepool argument with the **admin()** or **task()** function to manually create a chunk from an entry in the storage pool.
- create database argument: Create a database (SQL administration API)
  Use the create database argument with the **admin()** or **task()** function to create a database.
- create dbaccessdemo argument: Create the demonstration database (SQL administration API)
  Use the create dbaccessdemo argument with the **admin()** or **task()** function to create the **stores_demo** demonstration database.
- create dbspace argument: Create a dbspace (SQL administration API)
  Use the create dbspace argument with the **admin()** or **task()** function to create a dbspace.
- create dbspace from storagepool argument: Create a dbspace from the storage pool (SQL administration API)
  Use the create dbspace from storagepool argument with the **admin()** or **task()** function to create a permanent dbspace from an entry in the storage pool.
- create plogspace: Create a plogspace (SQL administration API)
  Use the create plogspace argument with the **admin()** or **task()** function to create a plogspace in which to store the physical log.
- create sbspace argument: Create an sbspace (SQL administration API)
  Use the create sbspace argument with the **admin()** or **task()** function to create an sbspace.
- create sbspace from storagepool argument: Create an sbspace from the storage pool (SQL administration API)
  Use the create sbspace from storagepool argument with the **admin()** or **task()** function to create an sbspace from an entry from the storage pool.
- create sbspace with accesstime argument: Create an sbspace that tracks access time (SQL administration API)
  Use the create sbspace with accesstime argument with the **admin()** or **task()** function to create an sbspace that tracks the time of access for all smart large objects stored in the sbspace.
- create sbspace with log argument: Create an sbspace with transaction logging (SQL administration API)
  Use the create sbspace with log argument with the **admin()** or **task()** function to create an sbspace with transaction logging turned on.
- create tempdbspace argument: Create a temporary dbspace (SQL administration API)
  Use the **create tempdbspace** argument with the **admin()** or **task()** function to create a temporary dbspace.
- create tempdbspace from storagepool argument: Create a temporary dbspace from the storage pool (SQL administration API)
  Use the create tempdbspace from storagepool argument with the **admin()** or **task()** function to create a temporary dbspace from an entry from the storage pool.
- create tempsbspace argument: Create a temporary sbspace (SQL administration API)
  Use the create sbspace argument with the **admin()** or **task()** function to create an sbspace.
- create tempsbspace from storagepool argument: Create a temporary sbspace from the storage pool (SQL administration API)
  Use the create tempsbspace from storagepool argument with the **admin()** or **task()** function to create a temporary sbspace from an entry from the storage pool.
- defragment argument: Dynamically defragment partition extents (SQL administration API)
  Use the defragment argument with the **admin()** or **task()** function to defragment tables or indexes to merge non-contiguous extents.
- drop blobspace argument: Drop a blobspace (SQL administration API)
  Use the drop blobspace argument with the **admin()** or **task()** function to drop the specified blobspace.
- drop blobspace to storagepool argument: Return space from an empty blobspace to the storage pool (SQL administration API)
  Use the drop blobspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty blobspace to the storage pool.
- drop chunk argument: Drop a chunk (SQL administration API)
  Use the drop chunk argument with the **admin()** or **task()** function to drop the specified chunk from a dbspace, blobspace, or sbspace.
- drop chunk to storagepool argument: Return space from an empty chunk to the storage pool (SQL administration API)
  Use the drop chunk to storagepool argument with the **admin()** or **task()** function to return the space from an empty chunk to the storage pool.
- drop database argument: Drop a database (SQL administration API)
  Use the drop database argument with the **admin()** or **task()** function to drop a database.
- drop dbspace argument: Drop a dbspace (SQL administration API)
  Use the drop dbspace argument with the **admin()** or **task()** function to drop the specified dbspace.
- drop dbspace to storagepool argument: Return space from an empty dbspace to the storage pool (SQL administration API)
  Use the drop dbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty dbspace to the storage pool.
- drop log argument: Drop a logical log (SQL administration API)
  Use the drop log argument with the **admin()** or **task()** function to drop the specified logical log.
- drop plogspace: Drop the plogspace (SQL administration API)
  Use the drop plogspace argument with the **admin()** or **task()** function to drop the plogspace.
- drop sbspace argument: Drop an sbspace (SQL administration API)
  Use the drop sbspace argument with the **admin()** or **task()** function to drop the specified sbspace.

- drop sbspace to storagepool argument: Return space from an empty sbspace to the storage pool (SQL administration API)
  Use the drop sbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty sbspace to the storage pool.
- drop tempdbspace argument: Drop a temporary dbspace (SQL administration API)
  Use the drop tempdbspace argument with the **admin()** or **task()** function to drop the specified temporary dbspace.
- drop tempdbspace to storagepool argument: Return space from an empty temporary dbspace to the storage pool (SQL administration API)
  Use the drop tempdbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty temporary dbspace to the storage pool.
- drop tempsbspace to storagepool argument: Return space from an empty temporary sbspace to the storage pool (SQL administration API)
  Use the drop tempsbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty temporary sbspace to the storage pool.
- export config argument: Export configuration parameter values (SQL administration API)
  Use the export config argument with the **admin()** or **task()** function to export a file that contains all configuration parameters and their current values.
- file status argument: Display the status of a message log file (SQL administration API)
  Use the file status argument with the **admin()** or **task()** function to specify the status of an online, ON-Bar activity, or ON-Bar debug message log file.
- grant admin argument: Grant privileges to run SQL administration API commands
  Use the grant admin argument with the **admin()** or **task()** function to grant privileges to run SQL administration API commands.
- ha make primary argument: Change the mode of a secondary server (SQL administration API)
  Use the ha make primary argument with the **admin()** or **task()** function to change the specified secondary server to a primary or standard server.
- ha rss argument: Create an RS secondary server (SQL administration API)
  Use the ha rss argument with the **admin()** or **task()** function to create a remote standalone (RS) secondary server.
- ha rss add argument: Add an RS secondary server to a primary server (SQL administration API)
  Use the ha rss add argument with the **admin()** or **task()** function to associate a primary server with a remote standalone (RS) secondary server.
- ha rss change argument: Change the password of an RS secondary server (SQL administration API)
  Use the ha rss change argument with the **admin()** or **task()** function to change the connection password for the specified RS secondary server.
- ha rss delete argument: Delete an RS secondary server (SQL administration API)
  Use the ha rss delete argument with the **admin()** or **task()** function to stop replication and delete the RS secondary server.
- ha sds clear argument: Stop shared-disk replication (SQL administration API)
  Use the ha sds clear argument with the **admin()** or **task()** function to stop replication to shared disk (SD) secondary servers and convert the primary server to a standard server.
- ha sds primary argument: Convert an SD secondary server to a primary server (SQL administration API)
  Use the ha sds primary argument with the **admin()** or **task()** function to change a shared disk (SD) secondary server to a primary server.
- ha sds set argument: Create a shared-disk primary server (SQL administration API)
  Use the ha sds set argument with the **admin()** or **task()** function to define a primary server to replicate to shared disk (SD) secondary servers.
- ha set idxauto argument: Replicate indexes to secondary servers (SQL administration API)
  Use the ha set idxauto argument with the **admin()** or **task()** function to control whether indexes are automatically replicated to secondary servers.
- ha set ipl argument: Log index builds on the primary server (SQL administration API)
  Use the ha set ipl argument with the **admin()** or **task()** function to control whether to log index builds on the primary server.
- ha set primary argument: Define an HDR primary server (SQL administration API)
  Use the ha set primary argument with the **admin()** or **task()** function to define a High-Availability Data Replication (HDR) primary server and specify the secondary server.
- ha set secondary argument: Define an HDR secondary server (SQL administration API)
  Use the ha set secondary argument with the **admin()** or **task()** function to define a High-Availability Data Replication (HDR) secondary server and specify the primary server.
- ha set standard argument: Convert an HDR server into a standard server (SQL administration API)
  Use the **ha set standard** argument with the **admin()** or **task()** function to convert a High-Availability Data Replication (HDR) primary or secondary server to a standard server.
- ha set timeout argument: Change SD secondary server timeout (SQL administration API)
  Use the ha set timeout argument with the **admin()** or **task()** function to change the amount of time in seconds that the primary server waits for acknowledgments from shared disk (SD) secondary servers.
- import config argument: Import configuration parameter values (SQL administration API)
  Use the import config argument with the **admin()** or **task()** function to import a file that contains one or more dynamically updatable configuration parameters and apply the new values.
- index compress repack shrink arguments: Optimize the storage of B-tree indexes (SQL administration API)
  Use the index compress repack shrink argument with the **admin()** or **task()** function to compress detached B-tree indexes, consolidate free space (repack), and return free space (shrink) in partitions.
- index estimate_compression argument: Estimate index compression (SQL administration API)
  Use the index estimate_compression argument with the **admin()** or **task()** function to estimate if you can save disk space by compressing a B-tree index.
- master_key reset argument: Change the keystore password (SQL administration API)
  Use the master_key reset argument with the **admin()** or **task()** function to change the password for the storage space encryption keystore. The password is used to encrypt the keystore for storage space encryption.
- message log delete argument: Delete a message log file (SQL administration API)
  Use the message log delete argument or file delete argument with the **admin()** or **task()** function to specify the particular online, ON-Bar activity, or ON-Bar debug message log to delete.
- message log rotate argument: Rotate the message log file (SQL administration API)
  Use the message log rotate argument or the file rotate argument with the **admin()** or **task()** function to specify the particular online, ON-Bar activity, or ON-Bar debug message log file to rotate, and to indicate the maximum number of message logs to rotate.
- message log truncate argument: Delete the contents of a message log file (SQL administration API)
  Use the message log truncate argument or file truncate argument with the **admin()** or **task()** function to specify the particular online, ON-Bar activity, or ON-Bar debug message log file to truncate. When the database server truncates a message log file, it deletes the messages in the log file, but keeps the log file.
- modify chunk extend argument: Extend the size of a chunk (SQL administration API)
  Use the modify chunk extend argument with the **admin()** or **task()** function to extend the size of the chunk by a specified minimum amount. The chunk must be marked as extendable.
- modify chunk extendable argument: Mark a chunk as extendable (SQL administration API)
  Use the modify chunk extendable argument with the **admin()** or **task()** function to specify that a particular chunk in an unmirrored dbspace or temporary dbspace can be extended..
- modify chunk extendable off argument: Mark a chunk as not extendable (SQL administration API)
  Use the modify chunk extendable off argument with the **admin()** or **task()** function to specify that a particular chunk cannot be extended.
- modify chunk swap_mirror argument: Switch primary and mirror chunk files without any downtime(SQL administration API)
  Use the modify chunk swap_mirror argument with the **admin()** or **task()** function to easily migrate data from old disk drives to new ones without downtime.
- modify space swap_mirror argument: Switch all primary and mirror chunk files for a space without any downtime (SQL administration API)
  Use the modify space swap_mirrors argument with the **admin()** or **task()** function to easily migrate data from old disk drives to new ones without downtime.

- modify config arguments: Modify configuration parameters (SQL administration API)
  Use the modify config argument with the **admin()** or **task()** function to change the value of a configuration parameter in memory until you restart the database server. Use the modify config persistent argument to change the value of a configuration parameter in memory and preserve the value in the onconfig file after you restart the server.
- modify space expand argument: Expand the size of a space (SQL administration API)
  Use the modify space expand argument with the **admin()** or **task()** function to immediately expand the size of a space, when you do not want to wait for Informix® to automatically expand the space.
- modify space sp_sizes argument: Modify sizes of an extendable storage space (SQL administration API)
  Use the modify space sp_sizes argument with the **admin()** or **task()** function to modify the create, extend, and maximum sizes that are associated with expanding a storage space. Modify the sizes to control how Informix uses storage pool entries for a particular storage space.
- onbar argument: Backup the storage spaces (SQL administration API)
  Use the onbar argument with the **admin()** or **task()** function to backup the storage spaces.
- onmode and a arguments: Add a shared-memory segment (SQL administration API)
  Use the onmode and a arguments with the **admin()** or **task()** function to add a shared-memory segment.
- onmode and c arguments: Force a checkpoint (SQL administration API)
  Use the onmode and c arguments with the **admin()** or **task()** function to force a checkpoint.
- onmode and C arguments: Control the B-tree scanner (SQL administration API)
  Use the onmode and C arguments with the **admin()** or **task()** function to control the B-tree scanner for cleaning indexes of deleted items.
- onmode and d arguments: Set data-replication types (SQL administration API)
  Use the onmode and d arguments with the **admin()** or **task()** function to change the mode of a server participating in high-availability data replication (HDR).
- onmode and D arguments: Set PDQ priority (SQL administration API)
  Use the onmode and D arguments with the **admin()** or **task()** function to temporarily reset the PDQ resources that the database server can allocate to any one decision-support query.
- onmode and e arguments: Change usage of the SQL statement cache (SQL administration API)
  Use the onmode and e arguments with the **admin()** or **task()** function to temporarily change the mode of the SQL statement cache.
- onmode and F arguments: Free unused memory segments (SQL administration API)
  Use the onmode and F arguments with the **admin()** or **task()** function to free unused memory segments.
- onmode and h arguments: Update sqlhosts caches (SQL administration API)
  Use the onmode and h arguments with the **admin()** or **task()** function to Update sqlhosts caches.
- onmode and j arguments: Switch the database server to administration mode (SQL administration API)
  Use the onmode and j arguments with the **admin()** or **task()** function to change the database server to administration mode.
- onmode and l arguments: Switch to the next logical log (SQL administration API)
  Use the onmode and l arguments with the **admin()** or **task()** function to switch the current logical-log file to the next logical-log file.
- onmode and m arguments: Switch to multi-user mode (SQL administration API)
  Use the onmode and m arguments with the **admin()** or **task()** function to change the database server to multi-user mode.
- onmode and M arguments: Temporarily change decision-support memory (SQL administration API)
  Use the onmode and M arguments with the **admin()** or **task()** function to temporarily change the size of memory available for parallel queries.
- onmode and n arguments: Unlock resident memory (SQL administration API)
  Use the onmode and n arguments with the **admin()** or **task()** function to end forced residency of the resident portion of shared memory.
- onmode and O arguments: Mark a disabled dbspace as down (SQL administration API)
  Use the onmode and O arguments with the **admin()** or **task()** function to mark a disabled dbspace as down so that the checkpoint that is being blocked by the disabled dbspace can continue and any blocked threads are released.
- onmode and p arguments: Add or remove virtual processors (SQL administration API)
  Use the onmode and p arguments with the **admin()** or **task()** function to dynamically add or remove virtual processors for the current database server session. This function does not update the onconfig file.
- onmode and Q arguments: Set maximum number for decision-support queries (SQL administration API)
  Use the onmode and Q arguments with the **admin()** or **task()** function to change the maximum number of concurrently executing decision-support queries.
- onmode and r arguments: Force residency of shared memory (SQL administration API)
  Use the onmode and r arguments with the **admin()** or **task()** function to start forced residency of the resident portion of shared memory.
- onmode and S arguments: Set maximum number of decision-support scans (SQL administration API)
  Use the onmode and S arguments with the **admin()** or **task()** function to change the maximum number of concurrently executing decision-support scans for the current session.
- onmode and W arguments: Reset statement cache attributes (SQL administration API)
  Use the onmode and W arguments with the **admin()** or **task()** function to change whether and when a statement can be inserted into the SQL cache.
- onmode and wf arguments: Permanently update a configuration parameter (SQL administration API)
  Use the onmode and wf arguments with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in the **onconfig** file.
- onmode and wm arguments: Temporarily update a configuration parameter (SQL administration API)
  Use the onmode and wm arguments with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in memory.
- onmode, wm, and AUTO_LRU_TUNING arguments: Change LRU tuning status (SQL administration API)
  Use the onmode, wm, and AUTO_LRU_TUNING arguments with the **admin()** or **task()** function to change the LRU tuning status without updating the onconfig file. .
- onmode and Y arguments: Change query plan measurements for a session (SQL administration API)
  Use the onmode and Y arguments with the **admin()** or **task()** function to change the output of query plan measurements for an individual session.
- onmode and z arguments: Terminate a user session (SQL administration API)
  Use the onmode and z arguments with the **admin()** or **task()** function to terminate the specified user session.
- onmode and Z arguments: Terminate a distributed transaction (SQL administration API)
  Use the onmode and Z arguments with the **admin()** or **task()** function to terminate the specified distributed transaction. Use this function only if communication between the participating database servers has been lost. If applications are performing distributed transactions, terminating one of the distributed transactions can leave your client/server database system in an inconsistent state.
- onsmsync argument: Synchronize with the storage manager catalog (SQL administration API)
  Use the onsmsync argument with the **admin()** or **task()** function to synchronize the **sysutils** database and emergency boot file with the storage manager catalog.
- onstat argument: Monitor the database server (SQL administration API)
  Use the onstat argument with the **admin()** or **task()** function to monitor the database server.
- ontape archive argument: Backup the data on your database (SQL administration API)
  Use the ontape archive argument with the **admin()** or **task()** function to create a backup of your database data.
- print error argument: Print an error message (SQL administration API)
  Use the print error argument with the **admin()** or **task()** function to print the message associated with the specified error number.
- print file info argument: Display directory or file information (SQL administration API)
  Use the print file info argument with the **admin()** or **task()** function to display information about a directory or a file
- print partition argument: Print partition information (SQL administration API)
  Use the print partition argument with the **admin()** or **task()** function to print the headers of a specified partition.

- rename space argument: Rename a storage space (SQL administration API)
  Use the rename space argument with the **admin()** or **task()** function to rename a dbspace, blobspace, sbspace, or extspace.
- reset config argument: Revert configuration parameter value (SQL administration API)
  Use the reset config argument with the **admin()** or **task()** function to revert the value of a dynamically updatable configuration parameter to its value in the onconfig file. Dynamically updatable configuration parameters are those parameters that you can change for a session with an **onmode** or SQL administration API command.
- reset config all argument: Revert all dynamically updatable configuration parameter values (SQL administration API)
  Use the reset config all argument with the **admin()** or **task()** function to revert the values of all dynamically updatable configuration parameter to their values in the onconfig file. Dynamically updatable configuration parameters are those parameters that you can change for a session with an **onmode** or SQL administration API command.
- reset sysadmin argument: Move the sysadmin database (SQL administration API)
  Use the reset sysadmin argument with the **admin()** or **task()** function to move the **sysadmin** database to the specified dbspace. Moving the **sysadmin** database resets the database back to the original state when it was first created; all data, **command history**, and results tables are lost. Only built-in tasks, sensors, and thresholds remain in the **sysadmin** tables.
- restart listen argument: Stop and start a listen thread dynamically (SQL administration API)
  Use the restart listen argument with the **admin()** or **task()** function to stop and then start an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.
- revoke admin argument: Revoke privileges to run SQL administration API commands
  Use the revoke admin argument with the **admin()** or **task()** function to revoke privileges to run SQL administration API commands.
- scheduler argument: Stop or start the scheduler (SQL administration API)
  Use the scheduler argument with the **admin()** or **task()** function to start or stop the scheduler.
- scheduler lmm enable argument: Specify automatic low memory management settings (SQL administration API)
  Use the scheduler lmm enable argument with the **admin()** or **task()** function to start automatic low memory management and to update low memory threshold settings.
- scheduler lmm disable argument: Stop automatic low memory management (SQL administration API)
  Use the scheduler lmm disable argument with the **admin()** or **task()** function to stop the current and subsequent invocations of automatic low memory management.
- set chunk argument: Change the status of a chunk (SQL administration API)
  Use the set chunk argument with the **admin()** or **task()** function to change the status of a blobspace, dbspace, or sbspace to online or offline.
- set dataskip argument: Start or stop skipping a dbspace (SQL administration API)
  Use the set dataskip argument with the **admin()** or **task()** function to specify whether the database server skips a dbspace that is unavailable during the processing of a transaction.
- set index compression argument: Change index page compression (SQL administration API)
  Use the set index compression argument with the **admin()** or **task()** function to modify the level at which two partially used index pages are merged.
- set onconfig memory argument: Temporarily change a configuration parameter (SQL administration API)
  Use the set onconfig memory argument with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in memory.
- set onconfig permanent argument: Permanently change a configuration parameter (SQL administration API)
  Use the set onconfig permanent argument with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in the **onconfig** file.
- set sbspace accesstime argument: Control access time tracking (SQL administration API)
  Use the set sbspace accesstime argument with the **admin()** or **task()** function to start or stop tracking the time of access for all smart large objects stored in the sbspace.
- set sbspace avg_lo_size argument: Set the average size of smart large objects (SQL administration API)
  Use the set sbspace avg_lo_size argument with the **admin()** or **task()** function to specify an expected average size of the smart large objects in the specified sbspace so that the database server can calculate the size of the metadata area.
- set sbspace logging argument: Change the logging of an sbspace (SQL administration API)
  Use the set sbspace logging argument with the **admin()** or **task()** function to specify whether the database server logs changes to the user data area of the sbspace.
- set sql tracing argument: Set global SQL tracing (SQL administration API)
  Use the set sql tracing argument with the **admin()** or **task()** function to set global SQL tracing.
- set sql tracing database argument: Change database tracing (SQL administration API)
  Use the set sql tracing database argument with the **admin()** or **task()** function to start or stop tracing for a database, or list which databases are being traced.
- set sql tracing session argument: Control tracing for a session (SQL administration API)
  Use the set sql tracing session argument with the **admin()** or **task()** function to change SQL tracing for the current session.
- set sql tracing user argument: Control tracing for users (SQL administration API)
  Use the set sql tracing user argument with the **admin()** or **task()** function to change SQL tracing for users.
- set sql user tracing argument: Set global SQL tracing for a user session (SQL administration API)
  Use the set sql user tracing argument with the **admin()** or **task()** function to set the mode of global SQL tracing for a specified user session.
- start json listener argument: Start the MongoDB API wire listener (deprecated)
  Use the start json listener argument with the **admin()** or **task()** function to start the MongoDB API wire listener.
- start listen argument: Start a listen thread dynamically (SQL administration API)
  Use the start listen argument with the **admin()** or **task()** function to start an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.
- start mirroring argument: Starts storage space mirroring (SQL administration API)
  Use the start mirroring argument with the **admin()** or **task()** function to start mirroring for a specified dbspace, blobspace, or sbspace.
- statement cache enable argument: Enable the SQL statement cache (SQL administration API)
  Use the statement cache enable argument with the **admin()** or **task()** function to enable the statement cache.
- statement cache flush argument: Flush the SQL statement cache (SQL administration API)
  Use the statement cache flush argument with the **admin()** or **task()** function to flush the statement cache.
- statement cache hits argument: Specify the number of hits in the SQL statement cache (SQL administration API)
  Use the statement cache hits argument with the **admin()** or **task()** function to specify the number of hits in the SQL statement cache.
- statement cache nolimit argument: Control whether to insert qualified statements into the SQL statement cache (SQL administration API)
  Use the statement cache nolimit argument with the **admin()** or **task()** function to control whether to insert statements into the SQL statement cache after its size is greater than the STMT_CACHE_SIZE value.
- statement cache off argument: Disable the SQL statement cache (SQL administration API)
  Use the statement cache off argument with the **admin()** or **task()** function to turn off the SQL statement cache.
- statement cache save argument: Save the SQL statement cache (SQL administration API)
  Use the statement cache save argument with the **admin()** or **task()** function to save the statement cache.
- statement cache restore argument: Restore the SQL statement cache (SQL administration API)
  Use the statement cache restore argument with the **admin()** or **task()** function to restore the statement cache.
- stop json listener: Stop the wire listener (deprecated)
  Use the stop json listener argument with the **admin()** or **task()** function to stop the wire listener.

- stop listen argument: Stop a listen thread dynamically (SQL administration API)
  Use the stop listen argument with the **admin()** or **task()** function to stop an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.
- stop mirroring argument: Stops storage space mirroring (SQL administration API)
  Use the stop mirroring argument with the **admin()** or **task()** function to stop mirroring for a specified dbspace, blobspace, or sbspace.
- storagepool add argument: Add a storage pool entry (SQL administration API)
  Use the storagepool add argument with the **admin()** or **task()** function to add an entry to the *storage pool* (a collection of available raw devices, cooked files, or directories that Informix can use to automatically add space to an existing storage space).
- storagepool delete argument: Delete one storage pool entry (SQL administration API)
  Use the storagepool delete argument with the **admin()** or **task()** function to delete an entry from the storage pool.
- storagepool modify argument: Modify a storage pool entry (SQL administration API)
  Use the storagepool modify argument with the **admin()** or **task()** function to modify an entry for a directory, cooked file, or raw device that Informix can use when additional storage space is required.
- storagepool purge argument: Delete storage pool entries (SQL administration API)
  Use the storagepool purge argument with the **admin()** or **task()** function to delete all storage pool entries, storage pool entries that have a status of `Full`, or storage pool entries that have a status of `Error`.
- Table and fragment pfsc_boost argument: Enable or disable a boosted partition free space cache (PFSC)
  You can enable and disable a boosted partition free space cache for a table or fragment using SQL administration API **admin()** or **task()** functions and arguments.
- Table and fragment compress and uncompress operations (SQL administration API)
  You can compress and uncompress the data in a table or in table fragments with SQL administration API **admin()** or **task()** functions and arguments. Compression operations apply only to the contents of data rows and the images of those data rows that appear in logical log records.
- tenant create argument: Create a tenant database (SQL Administration API)
  Use the **tenant create** argument with the **admin()** or **task()** function to create a tenant database.
- tenant drop argument: Drop a tenant database (SQL Administration API)
  Use the tenant drop argument with the **admin()** or **task()** function to drop a tenant database.
- tenant update argument: Modify tenant database properties (SQL Administration API)
  Use the tenant update argument with the **admin()** or **task()** function to modify the properties of a tenant database.

SQL Administration API Overview

Use the SQL administration API to remotely administer through SQL statements.

The SQL administration API consists of two functions: **admin()** and **task()**. These functions perform the same operations, but return results in different formats. These functions take one or more arguments that define the operation. Many of the operations are ones that you can also complete with command line utilities. The advantage of using the SQL administration API functions is that you can run them remotely from other database servers; whereas you must be directly connected to the database server on which to run command line utility commands.

You can invoke the **admin()** and **task()** functions within SQL statements that can include an expression, or you can use the EXECUTE FUNCTION statement to call them. Run the **admin()** or **task()** function within a transaction that does not include any other statements.
Note: When connected to a secondary node, the **admin()** function is disabled and will always return a value of -1. In addition, the **task()** function will return an error for commands that involve modifying disk structures, since these administrative actions are meant to be executed only on primary or standalone nodes.
The SQL administration API functions are defined in the **sysadmin** database. You must be connected to the **sysadmin** database, either directly or remotely, to run these functions.

The SQL administration API functions can be run only by the following users:

- The user **informix**
- The **root** user, if Connect privilege on the **sysadmin** database is granted to the user
- The DBSA group members, if Connect privilege on the **sysadmin** database is granted to the role
- Users granted privileges to SQL administration API commands by the **admin()** and **task()** functions with **grant admin** argument.

You can generate SQL administration API commands for reproducing the storage spaces, chunks, and logs that exist in a file. To do this, run the **dbschema** utility with the **-c** option.

- admin() and task() Function Syntax Behavior
  The **admin()** and **task()** functions take one or more arguments as quoted strings separated by commas.
- admin() and task() Argument Size Specifications
  By default, the units for arguments specifying sizes in **admin()** and **task()** functions are kilobytes. You can specify other units.
- admin() and task() Function Return Codes
  The **admin()** and **task()** functions perform equivalent tasks but produce different types of return codes. Use the **admin()** function if you want an integer return code, or the **task()** function if you want a textual return code.

Related information:
Storage space, chunk, and log creation

admin() and task() Function Syntax Behavior

The **admin()** and **task()** functions take one or more arguments as quoted strings separated by commas.

The syntax for the **admin()** and **task()** functions includes the following rules:

- Each argument must be delimited by a pair of single (') quotation marks or double (") quotation marks.

- Arguments must be separated by a comma.
- The maximum number of arguments is 28.
- Most arguments are not case-sensitive, with the following exceptions:
  - The argument that immediately follows the initial onmode argument is case-sensitive.
    For example:

    ```
    EXECUTE FUNCTION task("onmode","D","50");
    ```

  - The arguments included with the cdr argument are case-sensitive.
    For example:

    ```
    EXECUTE FUNCTION task("cdr define server",
                          "-c=g_amsterdam","--init g_amsterdam");
    ```

- If you are not directly connected to the **sysadmin** database, you must include the **sysadmin** database name and the server name, according to the standard Database Object Name syntax. For example, if your server name is **ids_server**, you could run the following statement:

  ```
  EXECUTE FUNCTION sysadmin@ids_server:admin("add bufferpool","2",
  "50000","8","60.0","50.0");
  ```

  For more information on the Database Object Name syntax, see the *IBM® Informix® Guide to SQL: Syntax*.

admin() and task() Argument Size Specifications

By default, the units for arguments specifying sizes in **admin()** and **task()** functions are kilobytes. You can specify other units.

You can use the following units in size arguments to the **admin()** and **task()** functions:

Notation	Corresponding Units
B	Bytes
K	Kilobytes (Default)
M	Megabytes
G	Gigabytes
T	Terabytes
P	Petabytes

The letter case of these characters is ignored.

Any white space that separates the size specification and the units abbreviation in the same argument is ignored. For example, the specifications `"128M"` and `"128 m"` are both interpreted as 128 megabytes.

When a size argument is omitted, the default size for that object applies, based either on the setting of a configuration parameter, or on the system default if no parameter is set. Storage spaces, for example, have a default size of 100 megabytes.

admin() and task() Function Return Codes

The **admin()** and **task()** functions perform equivalent tasks but produce different types of return codes. Use the **admin()** function if you want an integer return code, or the **task()** function if you want a textual return code.

When you run the **admin()** or **task()** function, it:

- Performs the specified operation.
- Returns a value that signifies whether the function succeeded or failed.
- Inserts a row into the **command_history** table of the **sysadmin** database.

The return codes for the **admin()** and **task()** functions indicate whether the function succeeded or failed in different formats:

- The **task()** function returns a textual message. The message is also inserted into the **cmd_ret_msg** column in the new row that the **task()** function inserts into the **command_history** table.
- The **admin()** function returns an integer. This number is also inserted into the **cmd_number** column in the new row that the **admin()** function inserts into the **command_history** table.
  - If this value is greater than zero, the function succeeded, and a new row was inserted into the **command_history** table.
  - If this value is zero, the function succeeded, but could not insert a new row into the **command_history** table.
  - If this value is less than zero, the function failed, but a new row was inserted into the **command_history** table.

The operation that the **admin()** or **task()** function specifies occurs in a separate transaction from the insertion of the new row into the **command_history** table. If the command executes successfully, but the insertion into the **command_history** table fails, the command takes effect, but an **online.log** error entry indicates the problem.

If the **command_history.cmd_number** serial counter is 200 when this function is called, and the command succeeds, then Informix® executes the command and returns the integer 201. If the command fails, this example returns the value –201.

Suppose the **task()** function had executed the same command:

```
EXECUTE FUNCTION task("check extents");
```

This command instructs the database server to check the extents, and returns a message indicating whether the command succeeded or failed.
If the **command_history.cmd_number** serial counter is 201 when this function is called, and the command fails, then the returned value is –202. Suppose that the next SQL administration API function that the DBSA invokes is this:

```
EXECUTE FUNCTION admin('create dbspace',
   'dbspace2', '/work/CHUNKS/dbspace2', "20M");
```

If in this case the command succeeds, the returned value is 203. The DBSA can use the following query to examine the two rows of the **command_history** table that these calls to the **admin()** function inserted:

```
SELECT * FROM command_history WHERE cmd_number IN (202,203);
```

This query returns two rows:

```
cmd_number       202
cmd_exec_time    2009-04-17 16:26:14
cmd_user         informix
cmd_hostname     olympia
cmd_executed     create dbspace
cmd_ret_status   -1
cmd_ret_msg      Unable to create file /work/dbspace2

cmd_number       203
cmd_exec_time    2009-04-17 16:26:15
cmd_user         informix
cmd_hostname     olympia
cmd_executed     create dbspace
cmd_ret_status   0
cmd_ret_msg      created dbspace number 2 named dbspace2
```

Note: When connected to a secondary node, the **admin()** function is disabled and will always return a value of -1. In addition, the **task()** function will return an error for commands that involve modifying disk structures, since these administrative actions are meant to be executed only on primary or standalone nodes.

SQL administration API portal: Arguments by privilege groups

You can view a list of **admin()** and **task()** function arguments, which are sorted by privilege groups, with links to information about the arguments.

Privilege groups identify what SQL administration API commands a user can run. Some function arguments are in multiple privilege groups. Privilege groups are granted to users so that they can run the commands that they need for their jobs. By default, only user **informix** or the DBSA can run SQL administration API commands.

Use the **grant admin** argument to grant privileges and the **revoke admin** argument to revoke privileges.

- ADMIN: The user can run all SQL administration API functions.
- BAR privilege group: The user can run backup and restore functions.
- FILE privilege group: The user can manage the message log and display file information.
- GRANT privilege group: The user has the privilege to grant and revoke privileges.
- HA privilege group: The user can run high-availability functions.
- MISC privilege group: The user can administer the database server.
- MONITOR privilege group: The user can run all SQL administration API functions that only display information.
- OPERATOR: The user can run all SQL administration API functions except functions in the GRANT privilege group.
- REPLICATION privilege group: The user can run Enterprise Replication **cdr** utility functions.
- SQL privilege group: The user can run functions that are related to SQL statements for managing databases.
- SQLTRACE privilege group: The user can run SQL tracing functions.
- STORAGE privilege group: The user can run space-related functions.
- TENANT privilege group: The user can run tenant database functions.
- WAREHOUSE: The user can run Informix® Warehouse Accelerator administration tools. See Permissions for administering Informix Warehouse Accelerator.

BAR privilege group

The BAR privilege group includes SQL administration API function arguments to back up your databases.

Table 1. **admin()** and **task()** Function Arguments for backup and restore

Argument	Version
archive fake argument: Perform an unrecorded backup (SQL administration API)	11.50.xC1
ontape archive argument: Backup the data on your database (SQL administration API)	11.70.xC2
onbar argument: Backup the storage spaces (SQL administration API)	11.70.xC2
onsmsync argument: Synchronize with the storage manager catalog (SQL administration API)	11.70.xC2

FILE privilege group

The FILE privilege group includes SQL administration API function arguments to manage message logs and display file information.

Table 2. **admin()** and **task()** Function Arguments for Message Log Commands

Argument	Version
file status argument: Display the status of a message log file (SQL administration API)	11.10.xC3
message log rotate argument: Rotate the message log file (SQL administration API)	11.10.xC3
message log delete argument: Delete a message log file (SQL administration API)	11.10.xC3
message log truncate argument: Delete the contents of a message log file (SQL administration API)	11.10.xC3
print file info argument: Display directory or file information (SQL administration API)	11.70.xC2

GRANT privilege group

The GRANT privilege group includes SQL administration API function arguments to grant or revoke privileges for running SQL administration API commands to other users.

Table 3. **admin()** and **task()** Function Arguments for granting and revoking privileges

Argument	Version
grant admin argument: Grant privileges to run SQL administration API commands	12.10.xC1
revoke admin argument: Revoke privileges to run SQL administration API commands	12.10.xC1

HA privilege group

The HA privilege group includes SQL administration API function arguments to manage high-availability clusters.

Table 4. **admin()** and **task()** Function Arguments for high-availability cluster Commands

Argument	Version
ha make primary argument: Change the mode of a secondary server (SQL administration API)	11.50.xC1
ha rss argument: Create an RS secondary server (SQL administration API)	11.50.xC1
ha rss add argument: Add an RS secondary server to a primary server (SQL administration API)	11.50.xC1
ha rss change argument: Change the password of an RS secondary server (SQL administration API)	11.50.xC1
ha rss delete argument: Delete an RS secondary server (SQL administration API)	11.50.xC1
ha sds clear argument: Stop shared-disk replication (SQL administration API)	11.50.xC1
ha sds primary argument: Convert an SD secondary server to a primary server (SQL administration API)	11.50.xC1
ha sds set argument: Create a shared-disk primary server (SQL administration API)	11.50.xC1
ha set idxauto argument: Replicate indexes to secondary servers (SQL administration API)	11.50.xC1
ha set ipl argument: Log index builds on the primary server (SQL administration API)	11.50.xC1
ha set primary argument: Define an HDR primary server (SQL administration API)	11.50.xC1
ha set secondary argument: Define an HDR secondary server (SQL administration API)	11.50.xC1
ha set standard argument: Convert an HDR server into a standard server (SQL administration API)	11.50.xC1
ha set timeout argument: Change SD secondary server timeout (SQL administration API)	11.50.xC1
onmode and d arguments: Set data-replication types (SQL administration API)	11.50.xC1

MISC privilege group

The MISC privilege group includes SQL administration function arguments to administer the database server:

- onstat
- Configuration parameters
- Data, partitions, and extents
- Listen threads
- Message log
- Memory
- PDQ
- Server mode
- SQL statement cache
- Other administrative tasks

onstat

SQL administration API function arguments to monitor the database server by running **onstat** commands.

Table 5. **admin()** and **task()** Function Arguments for onstat Commands

Argument	Version
onstat argument: Monitor the database server (SQL administration API)	12.10.xC1

Configuration parameters

SQL administration API function arguments to update configuration parameters.

Table 6. **admin()** and **task()** Function Arguments for Configuration Parameter Commands

Argument	Version
export config argument: Export configuration parameter values (SQL administration API)	12.10xC1
import config argument: Import configuration parameter values (SQL administration API)	12.10xC1
modify config arguments: Modify configuration parameters (SQL administration API)	12.10xC1
onmode and wf arguments: Permanently update a configuration parameter (SQL administration API)	11.10.xC1
onmode and wm arguments: Temporarily update a configuration parameter (SQL administration API)	11.10.xC1
onmode, wm, and AUTO_LRU_TUNING arguments: Change LRU tuning status (SQL administration API)	11.10.xC1
reset config argument: Revert configuration parameter value (SQL administration API)	12.10xC1
reset config all argument: Revert all dynamically updatable configuration parameter values (SQL administration API)	12.10xC1
set onconfig memory argument: Temporarily change a configuration parameter (SQL administration API)	11.50.xC3
set onconfig permanent argument: Permanently change a configuration parameter (SQL administration API)	11.50.xC3

Data, partitions, and extents

SQL administration API function arguments to manage data, partitions, and extents.

Table 7. **admin()** and **task()** Function Arguments for Data, Partition, and Extent Commands

Argument	Version
check data argument: Check data consistency (SQL administration API)	11.10.xC1
check extents argument: Check extent consistency (SQL administration API)	11.10.xC1
check partition argument: Check partition consistency (SQL administration API)	11.10.xC1
checkpoint argument: Force a checkpoint (SQL administration API)	11.10.xC1
create dbaccessdemo argument: Create the demonstration database (SQL administration API)	12.10.xC1
onmode and C arguments: Control the B-tree scanner (SQL administration API)	11.10.xC1
onmode and c arguments: Force a checkpoint (SQL administration API)	11.10.xC1
print partition argument: Print partition information (SQL administration API)	11.10.xC1
set dataskip argument: Start or stop skipping a dbspace (SQL administration API)	11.10.xC1
set index compression argument: Change index page compression (SQL administration API)	11.50.xC2

Listen threads

SQL administration API function arguments to control listen threads for a SOCTCP or TLITCP network protocol without interrupting existing connections.

Table 8. **admin()** and **task()** Function Arguments for Listen Thread Commands

Argument	Version
restart listen argument: Stop and start a listen thread dynamically (SQL administration API)	11.50.xC6
start listen argument: Start a listen thread dynamically (SQL administration API)	11.50.xC6
stop listen argument: Stop a listen thread dynamically (SQL administration API)	11.50.xC6

Message log

SQL administration API function arguments to manage message logs.

Table 9. **admin()** and **task()** Function Arguments for Message Log Commands

Argument	Version
file status argument: Display the status of a message log file (SQL administration API)	11.10.xC3
message log rotate argument: Rotate the message log file (SQL administration API)	11.10.xC3
message log delete argument: Delete a message log file (SQL administration API)	11.10.xC3
message log truncate argument: Delete the contents of a message log file (SQL administration API)	11.10.xC3

Memory

SQL administration API function arguments to manage memory.

Table 10. **admin()** and **task()** Function Arguments for Memory Commands

Argument	Version
add bufferpool argument: Add a buffer pool (SQL administration API)	11.10.xC1
add memory argument: Increase shared memory (SQL administration API)	11.10.xC1
onmode and a arguments: Add a shared-memory segment (SQL administration API)	11.10.xC1
onmode and F arguments: Free unused memory segments (SQL administration API)	11.10.xC1
onmode and n arguments: Unlock resident memory (SQL administration API)	11.10.xC1
onmode and r arguments: Force residency of shared memory (SQL administration API)	11.10.xC1
scheduler lmm enable argument: Specify automatic low memory management settings (SQL administration API)	11.70.xC3 11.50xC9
scheduler lmm disable argument: Stop automatic low memory management (SQL administration API)	11.70.xC3 11.50xC9

PDQ

SQL administration API function arguments to manage PDQ.

Table 11. **admin()** and **task()** Function Arguments for PDQ Commands

Argument	Version
onmode and D arguments: Set PDQ priority (SQL administration API)	11.10.xC1
onmode and M arguments: Temporarily change decision-support memory (SQL administration API)	11.10.xC1
onmode and Q arguments: Set maximum number for decision-support queries (SQL administration API)	11.10.xC1
onmode and S arguments: Set maximum number of decision-support scans (SQL administration API)	11.10.xC1

Server mode

SQL administration API function arguments to change the server mode.

Table 12. **admin()** and **task()** Function Arguments for Server Mode Commands

Argument	Version
onmode and j arguments: Switch the database server to administration mode (SQL administration API)	11.10.xC1
onmode and m arguments: Switch to multi-user mode (SQL administration API)	11.10.xC1

SQL statement cache

SQL administration API function arguments to manage the SQL statement cache.

Table 13. **admin()** and **task()** Function Arguments for SQL Statement Cache Commands

Argument	Version
onmode and e arguments: Change usage of the SQL statement cache (SQL administration API)	11.10.xC1
onmode and W arguments: Reset statement cache attributes (SQL administration API)	11.10.xC1

Other administrative tasks

SQL administration API function arguments to manage other administrative tasks.

Table 14. **admin()** and **task()** Function Arguments for other administrative task Commands

Argument	Version
alter logmode argument: Change the database logging mode (SQL administration API)	11.10.xC1
create dbaccessdemo argument: Create the demonstration database (SQL administration API)	12.10.xC1
onmode and e arguments: Change usage of the SQL statement cache (SQL administration API)	11.10.xC1
onmode and l arguments: Switch to the next logical log (SQL administration API)	11.10.xC1
onmode and p arguments: Add or remove virtual processors (SQL administration API)	11.10.xC1
onmode and Y arguments: Change query plan measurements for a session (SQL administration API)	11.10.xC1
onmode and z arguments: Terminate a user session (SQL administration API)	11.10.xC1
onmode and Z arguments: Terminate a distributed transaction (SQL administration API)	11.10.xC1
print error argument: Print an error message (SQL administration API)	11.10.xC1
reset sysadmin argument: Move the sysadmin database (SQL administration API)	11.10.xC1
scheduler argument: Stop or start the scheduler (SQL administration API)	11.10.xC1

MONITOR privilege group

The MONITOR privilege group includes SQL administration function arguments to monitor the message log, Enterprise Replication, and compression estimates.

Table 15. **admin()** and **task()** Function Arguments for monitoring the message log, Enterprise Replication, or compression estimates

Argument	Version
cdr error, **cdr finderr**, **cdr list repair**, **cdr list replicate**, **cdr list replicateset**, **cdr list server**, **cdr list template**, **cdr stats recv**, and **cdr stats rqm** arguments cdr argument: Administer Enterprise Replication (SQL administration API)	12.10.xC1
file status argument: Display the status of a message log file (SQL administration API)	11.10.xC3
index estimate_compression argument: Estimate index compression (SQL administration API)	12.10.xC1
print error argument: Print an error message (SQL administration API)	11.10.xC1
onstat argument: Monitor the database server (SQL administration API)	12.10.xC1
table estimate_compression and **fragment estimate_compression** arguments table or fragment arguments: Compress data and optimize storage (SQL administration API)	11.50.xC4

REPLICATION privilege group

The REPLICATION privilege group includes SQL administration API function arguments to manage Enterprise Replication.

Table 16. **admin()** and **task()** Function Arguments for Enterprise Replication Commands

Argument	Version
cdr argument: Administer Enterprise Replication (SQL administration API)	11.50.xC3

SQL privilege group

The SQL privilege group includes SQL administration API function arguments to create and drop databases and view error messages.

Table 17. **admin()** and **task()** Function arguments for databases and error messages

Argument	Version
create database argument: Create a database (SQL administration API)	11.70.xC2
create dbaccessdemo argument: Create the demonstration database (SQL administration API)	12.10.xC1
drop database argument: Drop a database (SQL administration API)	11.70.xC2
print error argument: Print an error message (SQL administration API)	11.10.xC1

SQLTRACE privilege group

The SQLTRACE privilege group includes SQL administration API function arguments to manage SQL tracing.

Table 18. **admin()** and **task()** Function Arguments for SQL Tracing Commands

Argument	Version
set sql tracing argument: Set global SQL tracing (SQL administration API)	11.10.xC1
set sql tracing database argument: Change database tracing (SQL administration API)	11.50.xC3
set sql tracing session argument: Control tracing for a session (SQL administration API)	11.50.xC3
set sql tracing user argument: Control tracing for users (SQL administration API)	11.10.xC1
set sql user tracing argument: Set global SQL tracing for a user session (SQL administration API)	11.50.xC3

STORAGE privilege group

The STORAGE privilege group includes SQL administration API function arguments for managing the following aspects of storage:

- Storage space encryption argument
- Automatic table storage location arguments
- Compression
- Logical and physical logs
- Mirroring
- Storage spaces
- Storage provisioning

Storage space encryption argument

SQL administration API function argument to change the master encryption key for storage space encryption.

Table 19. **admin()** and **task()** Function Arguments for storage space encryption command

Argument	Version

Argument	Version
master_key reset argument: Change the keystore password (SQL administration API)	12.10.xC8

Automatic table storage location arguments

SQL administration API function arguments to manage the list of dbspaces that store automatically allocated fragments.

Table 20. **admin()** and **task()** Function Arguments for table storage commands

Argument	Version
autolocate database add argument: Add a dbspace to the dbspace list (SQL administration API)	12.10.xC3
autolocate database anywhere argument: Add all dbspaces to the dbspace list (SQL administration API)	12.10.xC3
autolocate database argument: Specify dbspaces for automatic location and fragmentation (SQL administration API)	12.10.xC3
autolocate database off argument: Disable automatic fragmentation for a database (SQL administration API)	12.10.xC3
autolocate database remove argument: Remove a dbspace from the dbspace list (SQL administration API)	12.10.xC3

Compression

SQL administration API function arguments to manage the compression of data and to optimize storage.

Table 21. **admin()** and **task()** Function Arguments for Compression Commands

Argument	Version
index compress repack shrink arguments: Optimize the storage of B-tree indexes (SQL administration API)	12.10.xC1
index estimate_compression argument: Estimate index compression (SQL administration API)	12.10.xC1
table or fragment arguments: Compress data and optimize storage (SQL administration API)	11.50.xC4
purge compression dictionary arguments: Remove compression dictionaries (SQL administration API)	11.50.xC4

For an overview of compression and storage optimization commands, see Table and fragment compress and uncompress operations (SQL administration API).

Logical and physical logs

SQL administration API function arguments to manage logical and physical logs.

Table 22. **admin()** and **task()** Function Arguments for Log Commands

Argument	Version
add log argument: Add a new logical log (SQL administration API)	11.10.xC1
alter logmode argument: Change the database logging mode (SQL administration API)	11.10.xC1
alter plog argument: Change the physical log (SQL administration API)	11.10.xC1
drop log argument: Drop a logical log (SQL administration API)	11.10.xC1

Mirroring

SQL administration API function arguments to manage mirroring.

Table 23. **admin()** and **task()** Function Arguments for Mirror Commands

Argument	Version
add mirror argument: Add a mirror chunk (SQL administration API)	11.10.xC1
start mirroring argument: Starts storage space mirroring (SQL administration API)	11.10.xC1
stop mirroring argument: Stops storage space mirroring (SQL administration API)	11.10.xC1

Storage spaces

SQL administration API function arguments to manage chunks, blobspaces, dbspaces, and sbspaces.

Table 24. **admin()** and **task()** Function Arguments for Space Commands

Argument	Version
add chunk argument: Add a new chunk (SQL administration API)	11.10.xC1
alter chunk argument: Change chunk status to online or offline (SQL administration API)	11.10.xC1
clean sbspace argument: Release unreferenced smart large objects (SQL administration API)	11.10.xC1
create blobspace argument: Create a blobspace (SQL administration API)	11.10.xC1
create chunk argument: Create a chunk (SQL administration API)	11.10.xC1
create dbaccessdemo argument: Create the demonstration database (SQL administration API)	12.10.xC1

Argument	Version
create dbspace argument: Create a dbspace (SQL administration API)	11.10.xC1
create sbspace argument: Create an sbspace (SQL administration API)	11.10.xC1
create sbspace with accesstime argument: Create an sbspace that tracks access time (SQL administration API)	11.70.xC4
create sbspace with log argument: Create an sbspace with transaction logging (SQL administration API)	11.70.xC4
create tempdbspace argument: Create a temporary dbspace (SQL administration API)	11.10.xC1
create tempsbspace argument: Create a temporary sbspace (SQL administration API)	11.70.xC4
drop blobspace argument: Drop a blobspace (SQL administration API)	11.10.xC1
drop chunk argument: Drop a chunk (SQL administration API)	11.10.xC1
drop dbspace argument: Drop a dbspace (SQL administration API)	11.10.xC1
drop sbspace argument: Drop an sbspace (SQL administration API)	11.10.xC1
drop tempdbspace argument: Drop a temporary dbspace (SQL administration API)	11.10.xC1
onmode and O arguments: Mark a disabled dbspace as down (SQL administration API)	11.10.xC1
print error argument: Print an error message (SQL administration API)	11.10.xC1
rename space argument: Rename a storage space (SQL administration API)	11.10.xC1
set chunk argument: Change the status of a chunk (SQL administration API)	11.10.xC1
set sbspace accesstime argument: Control access time tracking (SQL administration API)	11.10.xC1
set sbspace avg_lo_size argument: Set the average size of smart large objects (SQL administration API)	11.10.xC1
set sbspace logging argument: Change the logging of an sbspace (SQL administration API)	11.10.xC1

Storage provisioning

SQL administration API function arguments to manage chunks, blobspaces, dbspaces, and sbspaces from storage pools.

Table 25. **admin()** and **task()** Function Arguments for Storage Provisioning Space Commands

Argument	Version
create blobspace from storagepool argument: Create a blobspace from the storage pool (SQL administration API)	11.70.xC1
create chunk from storagepool argument: Create a chunk from the storage pool (SQL administration API)	11.70.xC1
create dbspace from storagepool argument: Create a dbspace from the storage pool (SQL administration API)	11.70.xC1
create plogspace: Create a plogspace (SQL administration API)	12.10.xC3
create sbspace from storagepool argument: Create an sbspace from the storage pool (SQL administration API)	11.70.xC1
create tempdbspace argument: Create a temporary dbspace (SQL administration API)	11.70.xC1
create tempsbspace from storagepool argument: Create a temporary sbspace from the storage pool (SQL administration API)	11.10.xC1
create tempdbspace from storagepool argument: Create a temporary dbspace from the storage pool (SQL administration API)	11.70.xC1
drop blobspace to storagepool argument: Return space from an empty blobspace to the storage pool (SQL administration API)	11.70.xC1
drop chunk to storagepool argument: Return space from an empty chunk to the storage pool (SQL administration API)	11.70.xC1
drop dbspace to storagepool argument: Return space from an empty dbspace to the storage pool (SQL administration API)	11.70.xC1
drop plogspace: Drop the plogspace (SQL administration API)	12.10.xC3
drop sbspace to storagepool argument: Return space from an empty sbspace to the storage pool (SQL administration API)	11.70.xC1
drop tempdbspace to storagepool argument: Return space from an empty temporary dbspace to the storage pool (SQL administration API)	11.70.xC1
drop tempsbspace to storagepool argument: Return space from an empty temporary sbspace to the storage pool (SQL administration API)	11.70.xC1
modify chunk extend argument: Extend the size of a chunk (SQL administration API)	11.70.xC1
modify chunk extendable off argument: Mark a chunk as not extendable (SQL administration API)	11.70.xC1
modify chunk extendable argument: Mark a chunk as extendable (SQL administration API)	11.70.xC1
modify space expand argument: Expand the size of a space (SQL administration API)	11.70.xC1
modify space sp_sizes argument: Modify sizes of an extendable storage space (SQL administration API)	11.70.xC1
storagepool add argument: Add a storage pool entry (SQL administration API)	11.70.xC1
storagepool modify argument: Modify a storage pool entry (SQL administration API)	11.70.xC1
storagepool delete argument: Delete one storage pool entry (SQL administration API)	11.70.xC1

Argument	Version
storagepool purge argument: Delete storage pool entries (SQL administration API)	11.70.xC1

TENANT privilege group

The TENANT privilege group includes SQL administration API function arguments to manage tenant databases.

Table 26. **admin()** and **task()** Function Arguments for Tenant Database Commands

Argument	Version
tenant create argument: Create a tenant database (SQL Administration API)	12.10.xC4
tenant drop argument: Drop a tenant database (SQL Administration API)	12.10.xC4
tenant update argument: Modify tenant database properties (SQL Administration API)	12.10.xC4

add bufferpool argument: Add a buffer pool (SQL administration API)

Use the add bufferpool argument with the **admin()** or **task()** function to create a buffer pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"add bufferpool"--,--"page_size"--)--;---------------------><
```

Element	Description	Key Considerations
page_size	The page size in KB.	The page size must be an integral multiple of the default page size, and cannot be greater than 16 KB. On Windows, the page size is always 4 KB.

Usage

Use add bufferpool argument to create a buffer pool for a page size that does not already have a buffer pool. All other characteristics of the buffer pool that you create are set to the values of the fields in the default line of the BUFFERPOOL configuration parameter.

This function is equivalent to the **onparams -b -g** command and the BUFFERPOOL configuration parameter.

Example

The following example adds a buffer pool with a page size of 8 KB:

```
EXECUTE FUNCTION task("add bufferpool","8");
```

Related reference:
onparams -b: Add a buffer pool
BUFFERPOOL configuration parameter

add chunk argument: Add a new chunk (SQL administration API)

Use the add chunk argument with the **admin()** or **task()** function to add a chunk to a dbspace or blobspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"add chunk"--,--"space_name"--,--"path_name"----------------->

>--+-------------------------------------------------------------------------+-->
   '-,--"disk_size"--+-------------------------------------------------------+-'
                     '-,--"offset"--+-------------------------------------+-'
                                    '-,--"mirror_path"--+-----------------+-'
                                                        '-,--"mirror_offset"-'

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
disk_size	The amount of disk space to add in kilobytes.	See admin() and task() Argument Size Specifications.
mirror_offset	The location of the mirror chunk.	
mirror_path	The path to the mirror chunk.	If you are adding a chunk to a mirrored storage space, you must also add a mirror chunk.
offset	The location of the new chunk.	
path_name	The path of the added disk space.	
space_name	The name of the dbspace, blobspace, or sbspace to which you are adding disk space.	

Usage

The size of the chunk must be equal to or greater than 1000 KB and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 4 TB.

This function is equivalent to the **onspaces -a** command.

Example

The following example adds a 5 MB chunk of raw disk space, at an offset of 5200 kilobytes, to a dbspace named **dbspc3**:

```
EXECUTE FUNCTION task("add chunk", "dbspc3","\\.\e:","5120","5200");
```

The following example adds a 10 MB mirror chunk to a blobspace named **blobsp3** with an offset of 200 kilobytes for both the primary and mirror chunks:

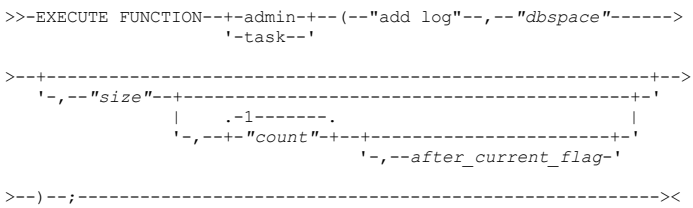
```
EXECUTE FUNCTION task("add chunk","blobsp3","/dev/raw_dev1","10240",
"200","/dev/raw_dev2","200");
```

Related reference:
onspaces -a: Add a chunk to a dbspace or blobspace
onspaces -a: Add a chunk to an sbspace

add log argument: Add a new logical log (SQL administration API)

Use the add log argument with the **admin()** or **task()** function to add a logical log to a dbspace.

Syntax



Element	Description	Key Considerations
after_current_flag	Whether to add the new log after the current log or after the last logical log (default).	Possible values are: • 1 = Add the new log after the current log. • 0 = Add the new log after the last log.
count	The number of log files to create. The default is 1.	The number must not cause the total number of logical-log files to exceed 32,767.
dbspace	The name of the dbspace in which to insert a logical-log file.	You can add a log file to a dbspace only if the database server has adequate contiguous space. You can add a log file during a backup. You cannot add a log file to a blobspace or sbspace.
size	The size in kilobytes of the new logical-log file. The default is the size specified by the LOGSIZE configuration parameter.	This value must be an unsigned integer greater than or equal to 200 KB. Also see admin() and task() Argument Size Specifications.

Usage

The newly added log files have a status of A and are immediately available for use. Use **onstat -l** to view the status of your logical-log files. It is recommended that you take a level-0 backup of the root dbspace and the dbspace that contains the log file as soon as possible after running this function.

By default, the new log file is added after the last logical log. Include `1` as the fifth argument to insert the logical-log file after the current log file.

This function resembles the **onparams -a -d** command, which can add a single logical-log file. You can add multiple logical-log files to the specified dbspace, however, with a single invocation of this function.

Example

The command in the following example adds three logical logs after the current log, each with a size of 5 MB:

```
EXECUTE FUNCTION task ("add log","logdbs","5M",3,1);
```

Related reference:
onparams -a -d dbspace: Add a logical-log file

add memory argument: Increase shared memory (SQL administration API)

Use the add memory argument with the **admin()** or **task()** function to add to the virtual portion of shared memory.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"add memory"--,--"memory_size"--)--;------------------------><
```

Element	Description	Key Considerations
memory_size	The size, in kilobytes, of the new virtual shared-memory segment.	This value must not exceed the operating system limit for the size of shared-memory segments. Also see admin() and task() Argument Size Specifications.

Usage

This size defaults to the SHMADD configuration parameter.

This function is equivalent to the **onmode -a** command.

Example

The following example adds 500 KB of virtual shared-memory:

```
EXECUTE FUNCTION task("add memory","500");
```

Related reference:
onmode -a: Add a shared-memory segment

add mirror argument: Add a mirror chunk (SQL administration API)

Use the add mirror argument with the **admin()** or **task()** function to add a mirror chunk to a dbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"add mirror"--,--"space_name"--,--"path_name"--,------------->

>--"offset"--,--"mirror_path"--,--"mirror_offset"--)--;-------><
```

Element	Description	Key Considerations
mirror_path	The disk partition or unbuffered device of the initial chunk of the dbspace, blobspace, or sbspace that performs the mirroring.	
mirror_offset	The offset to reach the mirrored chunk of the newly mirrored dbspace, blobspace, or sbspace.	See admin() and task() Argument Size Specifications.

Element	Description	Key Considerations
offset	The offset into the disk partition or into the unbuffered device in kilobytes to reach the initial chunk of the newly mirrored dbspace, blobspace, or sbspace.	See admin() and task() Argument Size Specifications.
path_name	The disk partition or unbuffered device of the initial chunk of the dbspace, blobspace, or sbspace that you want to mirror.	
space_name	The name of a dbspace, blobspace, or sbspace to mirror.	

Usage

This function is equivalent to the **onspaces -m** command.

Example

The following example adds a mirror chunk to a blobspace named **blobsp3**:

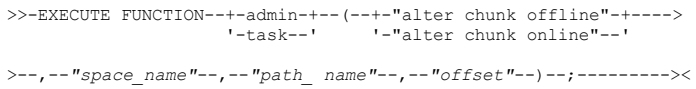
```
EXECUTE FUNCTION task("add mirror","blobsp3","/dev/raw_dev1",
"10240","/dev/raw_dev2","200");
```

Related reference:
onspaces -m: Start mirroring

alter chunk argument: Change chunk status to online or offline (SQL administration API)

Use the alter chunk argument with the **admin()** or **task()** function to bring a chunk online or take a chunk offline in a dbspace, blobspace, or sbspace.

Syntax



Element	Description	Key Considerations
space_name	The name of the blobspace, dbspace, or sbspace.	
path_name	The disk partition or unbuffered device of the chunk.	
offset	The offset (in kilobytes) into the disk partition or unbuffered device to reach the chunk. The default is 0.	See admin() and task() Argument Size Specifications.

Usage

The chunk must be in a mirrored pair, or a non-primary chunk within a noncritical dbspace.

Use the alter chunk online argument to change the chunk status to online.

Use the alter chunk offline argument to change the chunk status to offline.

This function is equivalent to the **onspaces -s** command.

Example

The following example brings a chunk in a space named dbspace4 online:

```
EXECUTE FUNCTION task("alter chunk online","dbspace4","/dev/raw_dev1","0");
```

Related reference:
onspaces -s: Change status of a mirrored chunk

alter logmode argument: Change the database logging mode (SQL administration API)

Use the alter logmode argument with the **admin()** or **task()** function to change the database logging mode to ANSI, buffered, non-logging, or unbuffered.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"alter logmode"--,--"database_name"--,--+-"a"-+--)--;------><
                                           +-"b"-+
                                           +-"n"-+
                                           '-"u"-'
```

Element	Description	Key Considerations
database_name	The name of the database with the logging mode that you want to alter.	

Usage

Unlike when you change the database logging mode with the **ondblog** or **ontape** utilities, when you use this function, the database remains accessible, and a level-0 backup is not always required. Ensure that no other session is active before running this function or it will fail.

Use the "a" argument to change the database logging to be ANSI compliant. After you create or convert a database to ANSI mode, you cannot change it back to any of the other logging modes.

Use the "b" argument to change the database logging to be buffered, so that transaction information is written to a buffer before it is written to a logical log.

Use the "n" argument to change the database logging to be non-logging, so that no database transactions are logged. You must perform a level-0 backup prior to using this argument.

Use the "u" argument to change the database logging to be unbuffered, so that data is not written to a buffer before it is written to a logical log.

Example

The following example changes the logging mode of a database named **employee** to unbuffered logging:

```
EXECUTE FUNCTION task("alter logmode","employee","u");
```

Related concepts:
The onlog utility

alter plog argument: Change the physical log (SQL administration API)

Use the alter plog argument with the **admin()** or **task()** function to change the location and size of the physical log.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"alter plog"--,--"dbspace"--+---------------------+--)--;---><
                               '-,--"phys_log_size"-'
```

Element	Description	Key Considerations
dbspace	The location of the physical log.	The space allocated for the physical log must be contiguous.
phys_log_size	The size, specified in kilobytes, of the physical log.	See admin() and task() Argument Size Specifications.

Usage

To change only the size, specify the current dbspace of the physical log.

This function is equivalent to the **onparams -p** command.

Example

The following example moves the physical log to a dbspace called **phsdbs**:

```
EXECUTE FUNCTION task ("alter plog","physdbs","49 M");
```

Related reference:
onparams -p: Change physical-log parameters

archive fake argument: Perform an unrecorded backup (SQL administration API)

Use the archive fake argument with the **admin()** or **task()** function to perform a backup operation to clone the data in a server without creating a persistent backup that could be used to perform a restore.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"archive fake"--)--;-------><
                     '-task--'
```

Usage

Use this function to populate the secondary server in a High-Availability Data Replication pair.

This function is equivalent to running the **ontape** command with the **-F** option.

Example

The following example starts an unrecorded backup:

```
EXECUTE FUNCTION task("archive fake");
```

autolocate database add argument: Add a dbspace to the dbspace list (SQL administration API)

Use the autolocate database add argument with the **admin()** or **task()** function to add a dbspace to the list of available dbspaces for the automatic location and fragmentation of tables for the specified database.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"autolocate database add"--,--"database_name"--,--"dbspace"-->

>--)--;-----------------------------------------------------><
```

Element	Description	Key Considerations
database_name	Name of the database	
dbspace	Name of a dbspace to add to the list of names of the dbspaces in which the database server can automatically create fragments.	The dbspace must exist.

Usage

The AUTOLOCATE configuration parameter or session environment variable must be set to a positive integer.

The list of available dbspaces is stored in the **sysautolocate** system catalog table.

Example

The following command adds the dbspace **dbspace9** to the list of available dbspaces for automatic location and fragmentation for tables in the **customer** database.

```
EXECUTE FUNCTION task("autolocate database add", "customer", "dbspace9");
```

Related reference:
AUTOLOCATE configuration parameter
autolocate database argument: Specify dbspaces for automatic location and fragmentation (SQL administration API)
autolocate database remove argument: Remove a dbspace from the dbspace list (SQL administration API)
autolocate database anywhere argument: Add all dbspaces to the dbspace list (SQL administration API)
autolocate database off argument: Disable automatic fragmentation for a database (SQL administration API)

autolocate database anywhere argument: Add all dbspaces to the dbspace list (SQL administration API)

Use the autolocate database anywhere argument with the **admin()** or **task()** function to specify that the database server can use any non-critical dbspace for the automatic location and fragmentation of tables for the specified database.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"autolocate database anywhere"--,--"database_name"--)--;---><
```

Element	Description	Key Considerations
database_name	Name of the database	Cannot be the name of a tenant database.

Usage

This command replaces any previous list of dbspaces with a list of all available dbspaces. Dbspaces that are dedicated to tenant database are not available. The list of available dbspaces is stored in the **sysautolocate** system catalog table.

The AUTOLOCATE configuration parameter or session environment variable must be set to a positive integer.

Example

The following command adds all non-critical dbspaces to the list of available dbspaces for automatic location and fragmentation for tables in the **potential_cust** database:

```
EXECUTE FUNCTION task("autolocate database anywhere", "potential_cust");
```

Related reference:
AUTOLOCATE configuration parameter
autolocate database argument: Specify dbspaces for automatic location and fragmentation (SQL administration API)
autolocate database add argument: Add a dbspace to the dbspace list (SQL administration API)
autolocate database remove argument: Remove a dbspace from the dbspace list (SQL administration API)
autolocate database off argument: Disable automatic fragmentation for a database (SQL administration API)

autolocate database argument: Specify dbspaces for automatic location and fragmentation (SQL administration API)

Use the autolocate database argument with the **admin()** or **task()** function to specify the list of available dbspaces for the automatic location and fragmentation of tables for the specified database.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"autolocate database"--,--"database_name"--,--"dbspace_list"-->

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
database_name	Name of the database	Cannot be the name of a tenant database.
dbspace_list	A comma-separated list of names of the dbspaces in which the database server can automatically create fragments.	The dbspaces must exist. The dbspaces cannot be dedicated to a tenant database.

Usage

The AUTOLOCATE configuration parameter or session environment variable must be set to a positive integer.

By default, all dbspaces are available. The list of available dbspaces is stored in the **sysautolocate** system catalog table.

Example

The following command limits the list of available dbspaces for automatic location and fragmentation for tables in the **customer** database:

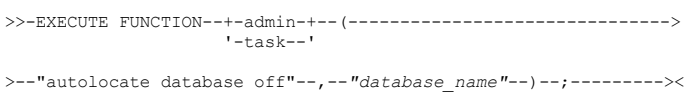
```
EXECUTE FUNCTION task("autolocate database", "customer",
 "dbspace1,dbspace2,dbspace4,dbspace8");
```

Related reference:
AUTOLOCATE configuration parameter
autolocate database add argument: Add a dbspace to the dbspace list (SQL administration API)
autolocate database remove argument: Remove a dbspace from the dbspace list (SQL administration API)
autolocate database anywhere argument: Add all dbspaces to the dbspace list (SQL administration API)
autolocate database off argument: Disable automatic fragmentation for a database (SQL administration API)

autolocate database off argument: Disable automatic fragmentation for a database (SQL administration API)

Use the autolocate database off argument with the **admin()** or **task()** function to disable the automatic location and fragmentation of tables for a specified database.

Syntax



Element	Description	Key Considerations
database_name	Name of the database	

Usage

New tables that you create in the specified database are stored in the same dbspace as the database and are not fragmented. Existing tables that were automatically fragmented are not allocated new fragments as the table grows.

Example

The following command disables automatic location and fragmentation of tables in the **customer_old** database:

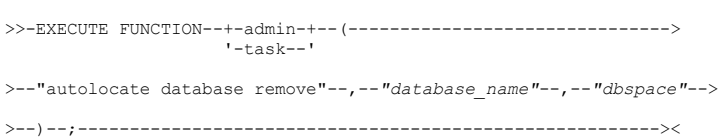
```
EXECUTE FUNCTION task("autolocate database off", "customer_old");
```

Related reference:
AUTOLOCATE configuration parameter
autolocate database argument: Specify dbspaces for automatic location and fragmentation (SQL administration API)
autolocate database add argument: Add a dbspace to the dbspace list (SQL administration API)
autolocate database remove argument: Remove a dbspace from the dbspace list (SQL administration API)
autolocate database anywhere argument: Add all dbspaces to the dbspace list (SQL administration API)

autolocate database remove argument: Remove a dbspace from the dbspace list (SQL administration API)

Use the autolocate database remove argument with the **admin()** or **task()** function to remove a dbspace from the list of available dbspaces into which the database server can automatically locate and fragment tables for the specified database.

Syntax



Element	Description	Key Considerations
database_name	Name of the database	
dbspace	Name of the dbspace to remove from the list of names of dbspaces in which the database server can automatically create fragments.	The dbspace must exist.

Usage

The AUTOLOCATE configuration parameter or session environment variable must be set to a positive integer.

The list of available dbspaces is stored in the **sysautolocate** system catalog table.

Example

The following command removes **dbspace1** from the list of available dbspaces for the **customer** database.

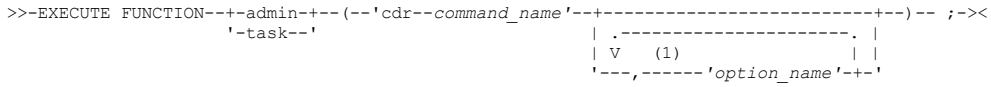
```
EXECUTE FUNCTION task("autolocate database remove", "customer", "dbspace1");
```

Related reference:
AUTOLOCATE configuration parameter
autolocate database argument: Specify dbspaces for automatic location and fragmentation (SQL administration API)
autolocate database add argument: Add a dbspace to the dbspace list (SQL administration API)
autolocate database anywhere argument: Add all dbspaces to the dbspace list (SQL administration API)
autolocate database off argument: Disable automatic fragmentation for a database (SQL administration API)

cdr argument: Administer Enterprise Replication (SQL administration API)

Use the cdr argument with the **admin()** or **task()** function to administer Enterprise Replication.

Syntax



Notes:

1. Maximum of six option arguments.

Element	Description	Key Considerations
command_name	The name of a **cdr** command.	You cannot include any hyphens, flags, or other constraining options to *command_name* that the **cdr** command-line utility requires. You cannot use abbreviations.
option_name	One or more elements of the **cdr** command-line options to the *command_name*.	The elements must be delimited by quotation marks. Also, include (in the correct order) any hyphens, flags, or other elements of **cdr** command-line options that the *command_name* requires. You can use abbreviations.

Usage

Use these functions to produce the same effect as with the **cdr** command-line utility to manage Enterprise Replication.

The SQL administration API supports **cdr** commands used to administer Enterprise Replication. The following commands for monitoring Enterprise Replication are not supported:

- **cdr list grid**
- **cdr list replicate**
- **cdr list replicateset**
- **cdr list server**
- **cdr list template**
- **cdr stats recv**
- **cdr stats rqm**
- **cdr –V**
- **cdr view**

The first argument must include only the **cdr** command names exactly as specified in the appendix for the **cdr** utility in the , such as **cdr define server**. Command names are case-sensitive and abbreviations (such as **cdr sto replset** instead of **cdr stop replicateset**) are **not** supported. The SQL administration API does not perform any validation before passing the parameters to the **cdr** utility.

The second and any following arguments include the command options. The options can be specified in one or up to six arguments.

The following example illustrates the use of the SQL administration API to define an Enterprise Replication server:

```
EXECUTE FUNCTION task ( 'cdr define server', '--connect=g_amsterdam
        --ats=/local0/er/ats --ris=/local0/er/ris --init g_amsterdam' );
```

The following example shows how the options can be spread over several arguments; the above statement can also be written as:

```
EXECUTE FUNCTION task( 'cdr define server',
                      '--connect=g_amsterdam',
                      '--ats=/local0/er/ats',
                      '--ris=/local0/er/ris',
                      '--init g_amsterdam' );
```

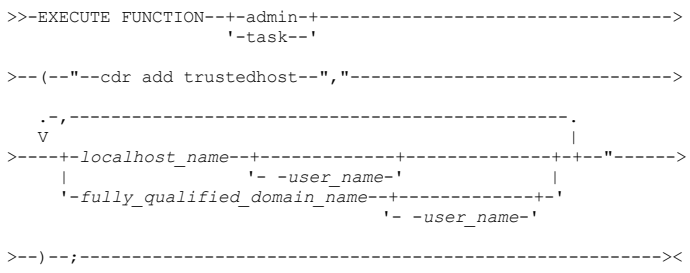
The following example shows double quoted strings within an argument:

```
EXECUTE FUNCTION task('cdr change replicate',
'-d repl_1 -"db1@server1:antonio.table1" "db2@server2:carlo.table2"');
```

cdr add trustedhost argument: Add trusted hosts (SQL administration API)

Use the cdr add trustedhost argument with the **admin()** or **task()** function to add trusted-host relationships for database servers in a high-availability cluster or Enterprise Replication domain. For a database to participate in a high-availability cluster or Enterprise Replication domain, its host must be listed in the trusted-host files of the other high-availability or replication servers.

Syntax



Element	Description	Key Considerations
localhost_name	The localhost name for a database server.	
fully_qualified_domain_name	The full domain name for a database server.	
user_name	A user account with authority over the database-server instance at the specified host.	

Usage

The cdr add trustedhost argument with the **admin()** or **task()** function adds values to the file that is specified by a database server's REMOTE_SERVER_CFG configuration parameter. If a database server is part of a high-availability cluster, trusted-host information also propagates to the trusted-host files of the other cluster servers. The trusted-host values specify the localhost names or fully qualified domain names for the other database servers in a shard cluster. For added security, you can specify user names that are associated with specific hosts.

If the REMOTE_SERVER_CFG configuration parameter is not set, and you run the SQL administration API **task()** or **admin()** function with the **cdr add trustedhost** argument, the database server performs the following actions:

1. The REMOTE_SERVER_CFG configuration parameter is set to authfile.*DBSERVER*.
2. The authfile.*DBSERVER* file is created in $INFORMIXDIR/etc.
3. The specified trusted-host information is added to $INFORMIXDIR/etc/authfile.*DBSERVER*.

If you run cdr add trustedhost argument with the **admin()** or **task()** function on a server in a high-availability cluster, the trusted-host information is added to the trusted-host files of all database servers in the cluster.

You must be a Database Server Administrator (DBSA) to run the **admin()** or **task()** function with the cdr add trustedhost argument.

To see the entries in the trusted host file, run the **admin()** or **task()** function with the cdr list trustedhost argument.

Example 1: Adding trusted host values to a trusted-host file

The following command adds six trusted-host values to the file specified by database server's REMOTE_SERVER_CFG configuration parameter:

```
EXECUTE FUNCTION task("cdr add trustedhost","myhost1, myhost1.ibm.com,
   myhost2, myhost2.ibm.com, myhost3, myhost3.ibm.com");
```

The task specifies localhost names and fully qualified domain names for three database servers.

Example 2: Adding trusted host and trusted user values to a trusted-host file

The following command adds four trusted host and user combinations to the file specified by database server's REMOTE_SERVER_CFG configuration parameter:

```
EXECUTE FUNCTION task("cdr add trustedhost", "myhost1 informix,
    myhost1.ibm.com informix, myhost2 user_1, myhost2.ibm.com user_1");
```

The task specifies localhost names, fully qualified domain names, and user names for two database servers.

Related reference:
REMOTE_SERVER_CFG configuration parameter
Related information:
Enabling sharding for JSON or relational data

cdr autoconfig serv argument: Autoconfigure connectivity and replication (SQL administration API)

The cdr autoconfig serv argument with the **admin()** or **task()** function can autoconfigure connectivity for servers in a high-availability cluster or Enterprise Replication domain, and can autoconfigure replication.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--'--cdr autoconfig serv--'---->
                     '-task--'

>--+-------------------------------------------------------------------------+-->
   '-,'--+----------------------+--+-| Source options |----------------------+-'
         '-| Connect Option  |-'  +-| Target options |----------------------+
                                   '-| Source options |--| Target options |-'

>--)--;-------------------------------------------------------><

Connect option

|--+- -c -server-------------+---------------------------------|
   +- --connect=server-------+
   +- -c -server_group-------+
   '- --connect=server_group-'

Source options

|-- --sourcehost--host-- --sourceport--port---------------------|

Target options

|-- --targethost--host-- --targetport--port---------------------|
```

Element	Purpose	Restrictions
host	The name of a database server host.	
port	The port number that is used for communication	
server	Name of the database server to connect to	The name must be the name of a database server or server connection.
server_group	Name of the database server group that includes the database server to connect to	The name must be the name of an existing database server group.

The following table describes the options to **cdr autoconfig serv**.

Long Form	Short Form	Meaning
--sourcehost	**-H**	The host of the database server that is sending autoconfiguration information. If **--sourcehost** and **--sourceport** are not specified, the database server where the function is run is considered the source database server.
--sourceport	**-P**	The port that is used by the database server that is sending autoconfiguration information.
--targethost	**-h**	The host of the database server that is receiving autoconfiguration information.
--targetport	**-p**	The port that is used by the database server that is receiving autoconfiguration information.

Usage

Run the **admin()** or **task()** function with the **cdr autoconfig serv** argument can autoconfigure connectivity for servers in a high-availability cluster or Enterprise Replication domain, and can autoconfigure replication if you are adding database servers to an Enterprise Replication domain. The CDR_AUTO_DISCOVER configuration parameter must be set to `1` on all database servers that are participating in an Enterprise Replication domain, before you can run the **admin()** or **task()** function with the **cdr autoconfig serv** argument. A newly installed database server that is added to an Enterprise Replication domain through the **cdr autoconfig serv** argument must have a configured storage pool.

If the source server is already configured for Enterprise Replication, the function performs the following actions:

1. The source server propagates its trusted-host file to target server.
2. The target server adds entries for itself and all other replication servers to its sqlhosts file.
3. The source server updates its sqlhost file with entries for the target server.
4. Each replication server updates its sqlhost file and trusted-host file with entries for the target server.

5. The target server sets its CDR_DBSPACE configuration parameter and creates the dbspace that is required for Enterprise Replication.
6. The target server sets its CDR_QDATA_SBSPACE configuration parameter and creates the sbspace that is required for Enterprise Replication.
7. The aborted transactions spooling (ATS) file directory $INFORMIXDIR/tmp/ats_*dbservername* is created on the target server.
8. The row information spooling (RIS) file directory $INFORMIXDIR/tmp/ris_*dbservername* is created on the target server.
9. Replication to the target server starts.

If the source server is not configured for Enterprise Replication, the function performs the additional actions:

1. The source server adds entries for itself to its sqlhosts file.
2. The source server sets its CDR_DBSPACE configuration parameter and creates the dbspace that is required for Enterprise Replication.
3. The source server sets its CDR_QDATA_SBSPACE configuration parameter and creates the sbspace that is required for Enterprise Replication.
4. The aborted transactions spooling (ATS) file directory $INFORMIXDIR/tmp/ats_*dbservername* is created on the source server.
5. The row information spooling (RIS) file directory $INFORMIXDIR/tmp/ris_*dbservername* is created on the source server.
6. Replication on the source server begins before replication on the target server begins.

The following restrictions apply to the **admin()** or **task()** function with the **cdr autoconfig serv** argument:

- All replication servers must be active, or the function fails.
- Do not run the **admin()** or **task()** function with the **cdr autoconfig serv** argument if you have configured trusted-host information, manually, rather than through running the **admin()** or **task()** function with the **cdr add trustedhost** argument.
- Do not run the **admin()** or **task()** function with the **cdr autoconfig serv** argument if your replication servers have secure ports that are configured.
- The **admin()** or **task()** function with the **cdr autoconfig serv** argument does not copy hosts.equiv information to the trusted-host file that is set by the REMOTE_SERVER_CFG configuration parameter. Run the **admin()** or **task()** function with the **cdr add trustedhost** argument if you must add information from the hosts.equiv file to the trusted-host file that is set by the REMOTE_SERVER_CFG configuration parameter.

Database servers are configured serially. Parallel configuration is not supported.

You can run this function as a **cdr utility** command.

Example 1: Configure Enterprise Replication on the local server

For this example, you have a local database server that is not configured for Enterprise Replication:

The following task function is run on the local server:

```
EXECUTE FUNCTION task('cdr autoconfig server');
```

The task function configures Enterprise Replication on the local server.

Example 2: Configure connectivity and ER between two stand-alone servers by using source syntax

For this example, you have two database servers:

- **server_1** on **host_1** is configured for Enterprise Replication
- **server_2** on **host_2** is not configured for Enterprise Replication

```
EXECUTE FUNCTION task('cdr autoconfig server', '--connect server_2
   --sourcehost host_1 --sourceport 9020');
```

The task function performs the following actions:

1. The command connects to **server_2**.
2. Enterprise Replication is defined on **server_2**.
3. **server_1** replicates its data to **server_2**

Example 3: Configure connectivity and ER between two stand-alone servers by using target syntax

The following command

```
EXECUTE FUNCTION task('cdr autoconfig server', '--connect server_1
   --targethost host_2 --targetport 9030');
```

The task function performs the following actions:

1. The command connects to **server_1**.
2. Enterprise Replication is defined on **server_2**.
3. **server_1** replicates its data to **server_2**

cdr autoconfig serv
CDR_AUTO_DISCOVER configuration parameter

cdr list trustedhost argument: List trusted hosts (SQL administration API)

Use the cdr list trustedhost argument with the **admin()** or **task()** function to list trusted-host information from the file that is specified by the database server's REMOTE_SERVER_CFG configuration parameter.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--("--cdr list trustedhost--");-->
                     '-task--'
```

Usage

You must be a Database Server Administrator (DBSA) to run this function.

Example

The following command lists the trusted-host entries from the database server's trusted-host file:

```
EXECUTE FUNCTION task("cdr list trustedhost");
```

The following example output shows a potential result of using the **cdr list trustedhost** argument.

```
myhost1 user_1
myhost1.example.com user_1
myhost2 user_2
myhost2.example.com user_2
```

Related reference:
REMOTE_SERVER_CFG configuration parameter
Related information:
Enabling sharding for JSON or relational data

cdr remove trustedhost argument: Remove trusted hosts (SQL administration API)

Use the cdr remove trustedhost argument with the **admin()** or **task()** function to remove entries from a database server's trusted-host file.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                     '-task--'

>--("--cdr remove trustedhost--","------------------------------>

   .-,-------------------------------------------.
   V                                             |
>----+-localhost_name---------------------------+-+--"--)--;--->
     +-fully_qualified_domain_name--------------+
     +-localhost_name-- -user_name--------------+
     '-fully_qualified_domain_name-- -user_name-'
```

Element	Description	Key Considerations
localhost_name	The localhost name for a database server.	If you do not specify a *user_name* in the command, all entries that include the specified host name are removed.
fully_qualified_domain_name	The full domain name for a database server.	If you do not specify a *user_name* in the command, all entries that include the specified fully qualified domain name are removed.
user_name	The user account with authority over the database-server instance at the specified host.	

Usage

The cdr remove trustedhost argument removes trusted-host entries from the trusted-host file that is specified by a database server's REMOTE_SERVER_CFG configuration parameter. For a database to participate in a high-availability cluster or Enterprise Replication domain, its host must be listed in the trusted-host files of the other high-availability or replication servers. When you run the **admin()** or **task()** function with the cdr remove trustedhost argument on a server in a high-availability cluster, the trusted-host entries are removed from the trusted host files of all cluster servers.

To see the entries in the trusted host file, run the **admin()** or **task()** function with the cdr list trustedhost argument.

You must be a Database Server Administrator (DBSA) to run the cdr remove trustedhost argument with the **admin()** or **task()** function.

Example 1: Removing host entries from a trusted-host file

The following command removes a localhost name value and a fully qualified domain name value from the trusted-host file that is specified by the database server's REMOTE_SERVER_CFG configuration parameter:

```
EXECUTE FUNCTION task("cdr remove trustedhost","myhost1, myhost1.ibm.com");
```

The **myhost1** and **myhost1.ibm.com** entries from the database server's trusted-host file are removed.

Example 2: Removing host and user entries from a trusted-host file

The following command removes localhost name values, fully qualified domain name values, and user name values from the trusted-host file that is specified by the database server's REMOTE_SERVER_CFG configuration parameter:

```
EXECUTE FUNCTION task("cdr remove trustedhost",
   "myhost2 john,myhost2.ibm.com john,myhost3 informix,myhost3.ibm.com informix");
```

The **myhost2** with user **john**, **myhost2.ibm.com** with user **john**,**myhost3** with user **informix**, and **myhost3.ibm.com** with user **informix** entries from the database server's trusted-host file are removed.

Related reference:
REMOTE_SERVER_CFG configuration parameter
Related information:
Enabling sharding for JSON or relational data

check data argument: Check data consistency (SQL administration API)

Use the check data argument with the **admin()** or **task()** function to check or repair all pages in the specified partition for consistency.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                     '-task--'

>--(--+-"check data"--------+--,--"partition_number"--)--;----->
      +-"check data only"---+
      '-"check data repair"-'
```

Element	Description	Key Considerations
partition_number	The partition number in which to check the data.	Find the partition numbers in the **partnum** column of the **systables** system catalog table.

Usage

Use the **check data** argument to read all pages, except for sbpages, and check each page for consistency. This argument is equivalent to the **oncheck -cD** command.

Use the **check data only** argument to read all pages, except for blobpages and sbpages, and check each page for consistency. This argument is equivalent to the **oncheck -cd** command.

Use the **check data repair** argument to repair inconsistent pages. This argument is equivalent to the **oncheck -cD -y** command.

Example

The following example checks the consistency of all pages in the partition `1048611`:

```
EXECUTE FUNCTION task("check data","1048611");
```

Related reference:
oncheck -cd and oncheck -cD commands: Check pages

check extents argument: Check extent consistency (SQL administration API)

Use the check extents argument with the **admin()** or **task()** function to verify that the extents on disk correspond to the current control information.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                     '-task--'

>--(--"check extents"--+------------------+--)--;------------->
                       '-,--dbspace_number-'
```

Element	Description	Key Considerations
dbspace_number	The number of the dbspace to check.	

Usage

Run this function to check each chunk-free list and corresponding free space and each tblspace extent. If you do not specify a dbspace number, all dbspaces are checked. The function checks dbspaces, blobspaces, smart-large-object extents, and user-data and metadata information in sbspace chunks.

This function is equivalent to the **oncheck -ce** command.

Example

The following example checks the extents in the dbspace with the number **2**:

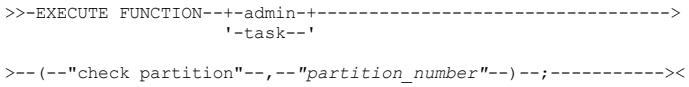
```
EXECUTE FUNCTION task("check extents",2);
```

Related reference:
oncheck -ce, -pe: Check the chunk-free list

check partition argument: Check partition consistency (SQL administration API)

Use the check partition argument with the **admin()** or **task()** function to print tblspace information for a table or fragment.

Syntax



Element	Description	Key Considerations
partition_number	The number of the partition that you want to check for consistency.	Find the partition numbers in the **partnum** column of the **systables** system catalog table.

Usage

The check partition argument with the **task()** function returns information that is equivalent to output of the **oncheck -pt** command. The output contains general information such as the maximum row size, the number of keys, the number and size of extents, the pages allocated and used per extent, the current serial value, and the date that the table was created.

The **admin()** function returns an integer that you can use to find information in the **command_history** table in the **sysadmin** database.

Example

The following example prints information for partition `1048611`:

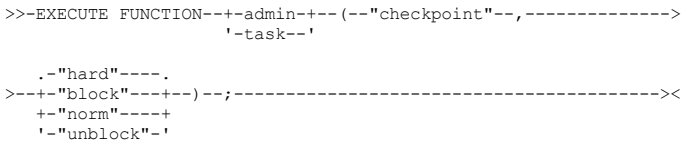
```
EXECUTE FUNCTION task("check partition","1048611");
```

Related reference:
oncheck -pt and -pT: Display tblspaces for a Table or Fragment

checkpoint argument: Force a checkpoint (SQL administration API)

Use the checkpoint argument with the **admin()** or **task()** function to force a checkpoint.

Syntax



Usage

This function forces a checkpoint that flushes the buffers to disk. You can use this function to force a checkpoint if the most recent checkpoint record in the logical log was preventing the logical-log file from being freed (status U-B-L).
Use the block argument to prevent the database server from processing any transactions. Use this option to perform an external backup on Informix®. While the database server is blocked, users cannot access it, except in read-only mode. No transactions can complete until the database server is unblocked.

Use the hard argument to force a blocking checkpoint. This is the default.

Use the norm argument to force a nonblocking checkpoint.

Use the unblock argument to unblock the database server. When the database server is unblocked, data transactions and normal database server operations can resume. Use this option after you complete an external backup on Informix.

This function is equivalent to the **onmode -c** command.

Example

The following example starts a blocking checkpoint:

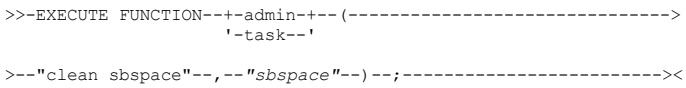
```
EXECUTE FUNCTION task("checkpoint","block");
```

Related reference:
onmode -c: Force a checkpoint

clean sbspace argument: Release unreferenced smart large objects (SQL administration API)

Use the clean sbspace argument with the **admin()** or **task()** function to release any unreferenced BLOB or CLOB objects from the sbspace.

Syntax



Element	Description	Key Considerations
sbspace	The name of the sbspace to clean.	

Usage

This function is equivalent to the **onspaces -cl** command.

Example

The following example cleans an sbspace named **sbsp1**:

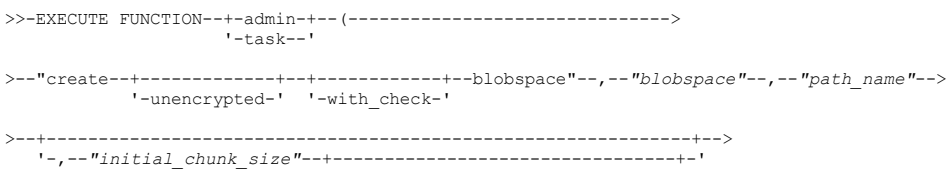
```
EXECUTE FUNCTION task("clean sbspace","sbsp1");
```

Related reference:
onspaces -cl: Clean up stray smart large objects in sbspaces

create blobspace argument: Create a blobspace (SQL administration API)

Use the create blobspace argument with the **admin()** or **task()** function to create a blobspace.

Syntax



```
                    '-,--"offset"--+----------------+-'
                                   '-,--"page_size"-'

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
blobspace	The name of the blobspace to be created.	
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new blobspace.	See admin() and task() Argument Size Specifications.
offset	The offset, in kilobytes, into the disk partition or into the device to reach the initial chunk of the new blobspace.	See admin() and task() Argument Size Specifications.
page_size	The blobspace blobpage size.	You specify the size of a blobpage in multiples of the default Informix® page size for your operating system. For more information, see blobpage size considerations in the *IBM® Informix Performance Guide*.
path_name	The disk partition or device of the initial chunk of the blobspace that you are creating.	

Usage

Use the create with_check blobspace argument to check the specified path name and return an error if it does not exist.

Use the **create unencrypted blobspace** argument to create an unencrypted blobspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -b** command.

Example

The following example creates a blobspace that has a size of 20 MB with an offset of 0 and page size of 2. The blob pages are 2*base page size = 8 K on Windows (4 K base page size).

```
EXECUTE FUNCTION task ("create with_check blobspace","blobs3",
"$INFORMIXDIR/WORK/blobs3","20 M","0","2");
```

Related reference:
onspaces -c -b: Create a blobspace
Avoid overwriting a chunk

create blobspace from storagepool argument: Create a blobspace from the storage pool (SQL administration API)

Use the create blobspace from storagepool argument with the **admin()** or **task()** function to create a blobspace from an entry from the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--create -+--------------+--blobspace from storagepool--"---->
              '-unencrypted-'

>--,--"blobspace"--,--"initial_chunk_size"--,--+-------------------------------------------+-->
                                               '-,--"blobpage_size"--+---------------------+-'
                                                                     '-,--"mirroring_flag"-'

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
blobspace	The name of the blobspace.	The blobspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the `$` character.
blobpage_size	The blobpage size, specified in terms of *page_unit*, the number of disk pages per blobpage	The page size is optional. However if you specify `1` for mirroring, you must also specify a page size.
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new blobspace.	See admin() and task() Argument Size Specifications.

Element	Description	Key Considerations
mirroring_flag	Either: • 1 = mirroring • 0 = no mirroring	The mirroring flag is optional.

Use the **create unencrypted blobspace from storagepool** argument to create an unencrypted blobspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

Examples

The following command creates a mirrored blobspace named `blobspace1`. The new blobspace has a size of 100 gigabytes and a blobpage size of 100 pages.

```
EXECUTE FUNCTION task("create blobspace from storagepool", "blobspace1", "100 GB",
 "100", "1");
```

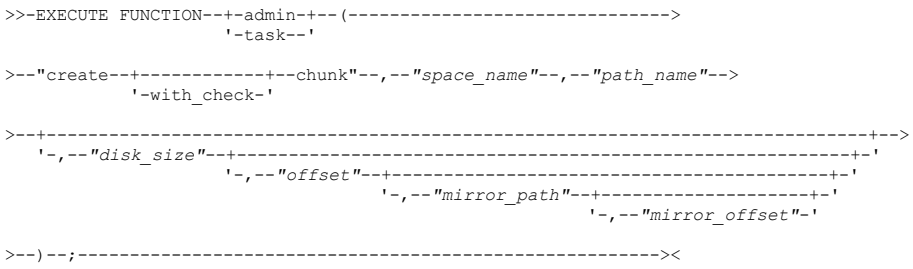
The following command creates an unmirrored blobspace named `blobspace2` with the default blobpage size, so a blobpage size is not specified:

```
EXECUTE FUNCTION task("create blobspace from storagepool", "blobspace2", "5000");
```

create chunk argument: Create a chunk (SQL administration API)

Use the create chunk argument with the **admin()** or **task()** function to create a chunk in a dbspace or in a blobspace.

Syntax



Element	Description	Key Considerations
disk_size	The amount of disk space to add in kilobytes.	See admin() and task() Argument Size Specifications.
mirror_offset	The location of the mirror chunk.	
mirror_path	The path to the mirror chunk. If you are adding a chunk to a mirrored storage space, you must also add a mirror chunk.	
offset	The location of the new chunk.	
path_name	The path of the added disk space.	
space_name	The name of the dbspace, blobspace, or sbspace to which you are adding disk space.	

Usage

Use the create with_check chunk argument to check the specified path name and return an error if it does not exist.

This function is equivalent to the **onspaces -a** command.

Example

The following example adds a 5 MB chunk of raw disk space, at an offset of 5200 kilobytes, to a dbspace named **dbspc3**:

```
EXECUTE FUNCTION task("create chunk", "dbspc3","\\.\e:","5120","5200");
```

The following example adds a 10 MB mirror chunk to a blobspace named **blobsp3** with an offset of 200 kilobytes for both the primary and mirror chunks:

```
EXECUTE FUNCTION task("create with_check chunk","blobsp3","/dev/raw_dev1","10240",
"200","/dev/raw_dev2","200");
```

Related reference:
onspaces -a: Add a chunk to a dbspace or blobspace
Avoid overwriting a chunk
onspaces -a: Add a chunk to an sbspace

create chunk from storagepool argument: Create a chunk from the storage pool (SQL administration API)

Use the create chunk from storagepool argument with the **admin()** or **task()** function to manually create a chunk from an entry in the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--create chunk from storagepool--"-------------------------->

>--,--"space_name"--,--"initial_chunk_size"--)--;-------------><
```

Element	Description	Key Considerations
space_name	The name of the storage space to which you are adding the chunk.	
initial_chunk_size	The size, in kilobytes, of the initial chunk.	See admin() and task() Argument Size Specifications.

Usage

You can also use an SQL administration API command with the modify space expand argument to manually create a chunk from the storage pool and add the chunk to the specified storage space. However, if the space has extendable chunks, Informix® might extend a chunk instead of creating a new one. Unlike the modify space expand argument, the create chunk from storagepool argument forces Informix to add a chunk.

Example

The following command adds a chunk to the dbspace named `logdbs`. The new chunk has a size of 200 megabytes.

```
EXECUTE FUNCTION task("create chunk from storagepool", "logdbs", "200 MB");
```

Related reference:
modify space expand argument: Expand the size of a space (SQL administration API)

create database argument: Create a database (SQL administration API)

Use the create database argument with the **admin()** or **task()** function to create a database.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"create database------------->
                     '-task--'

>--+-------------------------+--+-------------------------+----->
   '-with--+-log-----------+-'  '-+-nlscase insensitive-+-'
           +-buffered log--+      '-nlscase sensitive---'
           '-log mode ansi-'

>--"--,--"database_name"--+--------------------------------+----->
                          '-,--"dbspace"--+-------------+-'
                                          '-,--"locale"-'

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
database_name	The name of the database.	
dbspace	The name of the dbspace to store the data for this database. The default is the root dbspace.	The dbspace must already exist on the database server.
locale	The locale associated with the database.	The values for *locale* are the same as the values for the DB_LOCALE environment variable. If you omit this property, the locale is set by the value of the DB_LOCALE environment variable. The default locale is US English.

Usage

This function is equivalent to the CREATE DATABASE statement.

You cannot use this function to create a tenant database. You create a tenant database with the **tenant create** argument.

Examples

The following example creates the database named `demodbs` with unbuffered logging:

```
EXECUTE FUNCTION task("create database with log","demodbs");
```

The following example creates a database that is not case-sensitive named `demodbs2` with ANSI compliant logging in the dbspace named `dataspace1`:

```
EXECUTE FUNCTION task("create database with log mode ansi nlscase insensitive",
"demodbs2","dataspace1");
```

The following example creates a database named `demodbs3` with a French-Canadian locale in the dbspace name `dataspace1`:

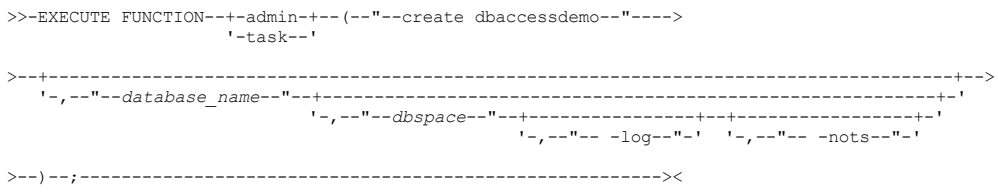
```
EXECUTE FUNCTION task("create database","demodbs3","dataspace1","fr_ca.8859-1");
```

Related reference:
tenant create argument: Create a tenant database (SQL Administration API)
Related information:
CREATE DATABASE statement
DB_LOCALE environment variable

create dbaccessdemo argument: Create the demonstration database (SQL administration API)

Use the create dbaccessdemo argument with the **admin()** or **task()** function to create the **stores_demo** demonstration database.

Syntax



Element	Purpose	Key considerations
database_name	The name of the database to create.	Default database name is **stores_demo**.
dbspace	The name of the dbspace in which to create the database.	Default dbspace is the root dbspace.

Usage

Run this function to create the **stores_demo** database.

Use the **-log** option to enable transaction logging for the demonstration database.

Use the **-nots** option to prevent the creation of the tables with time series data in the demonstration database.

Examples

The following command creates the **stores_demo** database in the root dbspace:

```
EXECUTE FUNCTION task("create dbaccessdemo");
```

The following command creates the demonstration database named **demo2**, in a dbspace named **dbs1**:

```
EXECUTE FUNCTION task("create dbaccessdemo","demo2","dbs1");
```

The following command creates the **stores_demo** database in a dbspace named **dbs1** with transaction logging:

```
EXECUTE FUNCTION task("create dbaccessdemo","stores_demo","dbs1","-log");
```

Related information:

create dbspace argument: Create a dbspace (SQL administration API)

Use the create dbspace argument with the **admin()** or **task()** function to create a dbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"create--+-+-------------+-+--dbspace"--,--"dbspace"--,--"path_name"-->
            | '-unencrypted-' |
            '-+------------+--'
              '-with_check-'

>--+-------------------------------------------------------------------------------------------------+-->
   '-,--"initial_chunk_size"--+-------------------------------------------------------------------+-'
                              '-,--"offset"--+-------------------------------------------------+-'
                                             '-,--"page_size"--+-------------------------------+-'
                                                               '-| Extents and mirror chunk |-'

>--)--;-------------------------------------------------------><

Extents and mirror chunk

|--+-------------------------------------------------------------------------------------------+--|
   '-,--"first_extsize"--+-----------------------------------------------------------------+-'
                         '-,--"next_extsize"--+-----------------------------------------+-'
                                              '-,--"mirror_path"--+-------------------+-'
                                                                  '-,--"mirror_offset"-'
```

Element	Description	Key Considerations
dbspace	The name of the dbspace to be created.	
first_extsize	The size, in KB, of the first extent for the tblspace **tblspace**.	See admin() and task() Argument Size Specifications.
initial_chunk_size	The size, in KB, of the initial chunk of the new dbspace. The size is rounded to a multiple of the page size.	See admin() and task() Argument Size Specifications.
mirror_offset	The offset, in KB, of the mirror chunk.	
mirror_path	The path name to the chunk that mirrors the initial chunk of the dbspace.	
next_extsize	The size, in KB, of the next extents in the tblspace **tblspace**.	See admin() and task() Argument Size Specifications.
offset	The offset, in KB, into the disk partition or into the device to reach the initial chunk of the new dbspace.	
page_size	The non-default page size, in KB, for the new dbspace.	See admin() and task() Argument Size Specifications.
path_name	The disk partition or device of the initial chunk of the dbspace that you are creating.	Valid page sizes depend on the default page size for the computer: • 2 KB default page size: 2, 4, 6, 8, 10, 12, or 16 KB • 4 KB default page size: 4, 8, 12, or 16 KB

Usage

Use the **create with_check dbspace** argument to check the specified path name and return an error if it does not exist.

Use the **create unencrypted dbspace** argument to create an unencrypted dbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -d** command.

Example

The following example creates a dbspace that has a size of 20 MB with an offset of 0.

```
EXECUTE FUNCTION task ("create dbspace", "dbspace3",
"$INFORMIXDIR/WORK/dbspace3", "20 M", "0");
```

Related reference:
onspaces -c -d: Create a dbspace
Avoid overwriting a chunk

DISK_ENCRYPTION configuration parameter

create dbspace from storagepool argument: Create a dbspace from the storage pool (SQL administration API)

Use the create dbspace from storagepool argument with the **admin()** or **task()** function to create a permanent dbspace from an entry in the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                     '-task--'

>--"--create -+-------------+--dbspace from storagepool--"------>
              '-unencrypted-'

>--,--"dbspace"--,--"initial_chunk_size"--,---------------------->

>--+-------------------------------------------------------------------------------------------+-->
   '-,--"page_size"--+-------------------------------------------------------------------------+-'
                     '-,--"mirroring_flag"--+-----------------------------------------+-'
                                            '-,--"first_extent"--+------------------+-'
                                                                 '-,--"next_extent"-'

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
dbspace	Name of the dbspace to be created.	Must be unique among dbspace names, and cannot exceed 128 bytes. It must begin with a letter or underscore, and can include only letters, digits, underscore (_) symbols, or the $ character.
first_extent	Size, in kilobytes, of the first extent for the tblspace **tblspace**.	See admin() and task() Argument Size Specifications.
initial_chunk_size	Size of the initial chunk of the new dbspace.	See admin() and task() Argument Size Specifications.
mirroring_flag	Either: • 1 = mirroring • 0 = no mirroring	The mirroring flag is optional. If none is specified, the default is an unmirrored dbspace.
next_extent	Size, in kilobytes, of the next extents in the tblspace **tblspace**	See admin() and task() Argument Size Specifications.
page_size	Nondefault page size, in kilobytes, for the new dbspace.	The page size is optional. If you specify 1 for mirroring, however, you must also specify a page size. Valid page sizes depend on the default page size for the computer: • 2 KiB default page size: 2, 4, 6, 8, 10, 12, or 16 KiB • 4 KiB default page size: 4, 8, 12, or 16 KiB

Use the **create unencrypted dbspace from storagepool** argument to create an unencrypted dbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

For the **admin()** or **task()** syntax for creating a temporary dbspace, see create tempdbspace argument: Create a temporary dbspace (SQL administration API).

Examples

The following command creates a mirrored dbspace named dbspace3. The new dbspace has a size of 1 gigabyte, a page size of 6 kilobytes, a tblspace **tblspace** first extent size of 200 kilobytes, and a next extent size of 400 kilobytes.

```
EXECUTE FUNCTION task("create dbspace from storagepool",
 "dbspace3",  "1 GB", "6", "1", "200", "400");
```

The following command creates an unmirrored dbspace named dbspace8. The size of the new dbspace is 50 megabytes. Because no page size is specified, the new dbspace has the default page size.

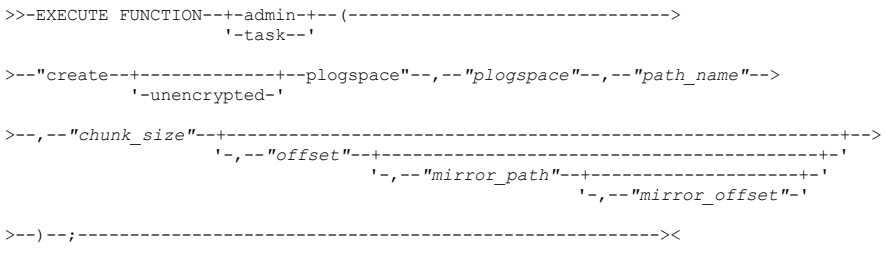
```
EXECUTE FUNCTION task("create dbspace from storagepool",
 "dbspace8", "50000");
```

Related reference:
DISK_ENCRYPTION configuration parameter

create plogspace: Create a plogspace (SQL administration API)

Use the create plogspace argument with the **admin()** or **task()** function to create a plogspace in which to store the physical log.

Syntax



Element	Description	Key Considerations
chunk_size	The size, in KB, of the chunk of the new plogspace. The size is rounded to a multiple of the page size.	See admin() and task() Argument Size Specifications.
mirror_offset	The offset, in KB, of the mirror chunk.	Unsigned integer. The size must be equal to or greater than 1000 KB and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 2 or 4 TB, depending on the platform.
mirror_path	The path name to the chunk that mirrors the chunk of the plogspace.	If you mirror the plogspace, the plogspace chunk cannot be extendable.
offset	The offset, in KB, into the disk partition or into the device to reach the chunk of the new plogspace.	Unsigned integer. The size must be equal to or greater than 1000 KB and a multiple of the page size. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum chunk size is 2 or 4 TB, depending on the platform.
path_name	The disk partition or device of the chunk of the plogspace that you are creating.	The chunk must be an existing unbuffered device or buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server. UNIX example (unbuffered device): /dev/rdsk/c0t3d0s4 UNIX example (buffered device): /ix/ifmx/db1chunk Windows example: c:\Ifmxdata\ol_icecream\mychunk1.dat
plogspace	The name of the plogspace to be created.	The plogspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the $ character. The syntax must conform to the Identifier segment. For more information, see Identifier.

Usage

Use the **create unencrypted plogspace** argument to create an unencrypted plogspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -P** command.

An instance can have only one plogspace. If a plogspace exists, when you create a new plogspace, the physical log is moved to the new space and the old plogspace is dropped.

The physical log must be stored on a single chunk. The chunk is marked as extendable by default so that the database server can expand the plogspace if necessary to expand the physical log. If you mirror the plogspace, the space cannot expand because a mirror chunk cannot be extendable.

Examples

The following example creates a plogspace that has a size of 30000 KB with an offset of 0.

```
EXECUTE FUNCTION task ("create plogspace", "plogdbs",
"/dev/chk1", 30000, 0);
```

The following example creates a mirrored plogspace that has a size of 30000 KB with an offset of 0.

```
EXECUTE FUNCTION task ("create plogspace", "plogdbs",
"/dev/chk1", 30000, 0, "/dev/mchk1", 0);
```

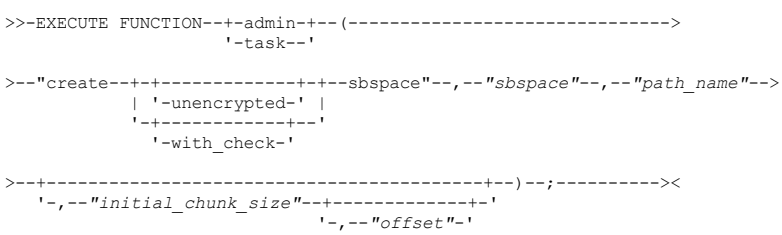
Related information:
Plogspace
Manage the plogspace

create sbspace argument: Create an sbspace (SQL administration API)

Use the create sbspace argument with the **admin()** or **task()** function to create an sbspace.

Syntax



Element	Description	Key Considerations
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new sbspace.	See admin() and task() Argument Size Specifications.
offset	The offset, in kilobytes, into the disk partition or into the device to reach the initial chunk of the new sbspace.	
path_name	The disk partition or unbuffered device of the initial chunk of the sbspace.	
sbspace	The name of the sbspace to be created.	

Usage

Use the **create with_check sbspace** argument to check the specified path name and return an error if it does not exist.

Use the **create unencrypted sbspace** argument to create an unencrypted sbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -S** command.

Example

The following example creates a new sbspace that has a size of 20 MB with an offset of 0:

```
EXECUTE FUNCTION task ("create sbspace","sbspace2",
"$INFORMIXDIR/WORK/sbspace2","20 M","0");
```

Related reference:
onspaces -c -S: Create an sbspace
Avoid overwriting a chunk
create tempsbspace argument: Create a temporary sbspace (SQL administration API)
DISK_ENCRYPTION configuration parameter

create sbspace from storagepool argument: Create an sbspace from the storage pool (SQL administration API)

Use the create sbspace from storagepool argument with the **admin()** or **task()** function to create an sbspace from an entry from the storage pool.

Syntax

```
>--"--create -+--------------+--sbspace from storagepool--"------>
              '-unencrypted-'

>--,--"sbspace"--,--"initial_chunk_size"--+-------------------------------------------+-->
                                          '-,--"logging_flag"--+---------------------+-'
                                                               '-,--"mirroring_flag"-'

>--)--;-----------------------------------------------------><
```

Element	Description	Key Considerations
sbspace	The name of the sbspace.	The sbspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the `$` character.
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new sbspace.	See admin() and task() Argument Size Specifications.
logging_flag	Either: • `1` = logging • `0` = no logging	The logging flag is optional. However if you specify `1` for mirroring, you must also specify a logging flag.
mirroring_flag	Either: • `1` = mirroring • `0` = no mirroring	The mirroring flag is optional.

Use the **create unencrypted sbspace from storagepool** argument to create an unencrypted sbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

Examples

The following command creates a mirrored and logged sbspace named `sbspace1`. The new sbspace has a size of 240 megabytes.

```
EXECUTE FUNCTION task("create sbspace from storagepool", "sbspace1",
 "240 MB", "1", "1");
```

The following command creates an unmirrored and unlogged sbspace named `sbspace2`. This sbspace has a size of 5 gigabytes.

```
EXECUTE FUNCTION task("create sbspace from storagepool", "sbspace2", "5 GB");
```

Related reference:
DISK_ENCRYPTION configuration parameter

create sbspace with accesstime argument: Create an sbspace that tracks access time (SQL administration API)

Use the create sbspace with accesstime argument with the **admin()** or **task()** function to create an sbspace that tracks the time of access for all smart large objects stored in the sbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"create--+-------------+--+-------------+--sbspace with accesstime"--,--"sbspace"--,--"path_name"-->
            '-unencrypted-'  '-with_check-'

>--+-------------------------------------------+--)--;---------><
   '-,--"initial_chunk_size"--+-------------+-'
                              '-,--"offset"-'
```

Element	Description	Key Considerations
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new sbspace.	See admin() and task() Argument Size Specifications.
offset	The offset, in kilobytes, into the disk partition or into the device to reach the initial chunk of the new sbspace.	
path_name	The disk partition or unbuffered device of the initial chunk of the sbspace.	
sbspace	The name of the sbspace to be created.	

Usage

Use the **create with_check sbspace with accesstime** argument to check the specified path name and return an error if it does not exist.

Use the **create unencrypted sbspace with accesstime** argument to create an unencrypted sbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -S** command for creating an sbspace and using the set sbspace accesstime argument with the **admin()** or **task()** function to start tracking the time of access for all smart large objects stored in the sbspace.

Example

The following example creates a new sbspace that tracks access time. This sbspace has a size of 20 MB with an offset of 0:

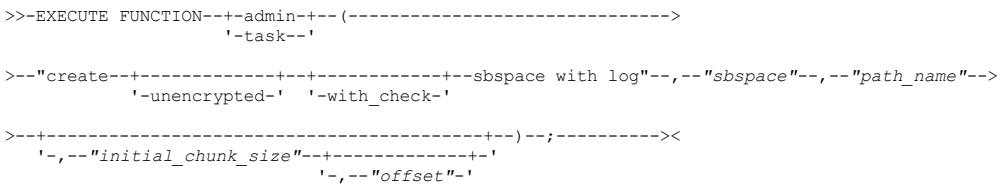
```
EXECUTE FUNCTION task ("create sbspace with accesstime","sbspace4",
"$INFORMIXDIR/WORK/sbspace4","20 M","0");
```

Related reference:
set sbspace accesstime argument: Control access time tracking (SQL administration API)
DISK_ENCRYPTION configuration parameter

create sbspace with log argument: Create an sbspace with transaction logging (SQL administration API)

Use the create sbspace with log argument with the **admin()** or **task()** function to create an sbspace with transaction logging turned on.

Syntax



Element	Description	Key Considerations
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new sbspace.	See admin() and task() Argument Size Specifications.
offset	The offset, in kilobytes, into the disk partition or into the device to reach the initial chunk of the new sbspace.	
path_name	The disk partition or unbuffered device of the initial chunk of the sbspace.	
sbspace	The name of the sbspace to be created.	

Usage

Use the **create with_check sbspace with log** argument to check the specified path name and return an error if it does not exist.

Use the **create unencrypted sbspace with log** argument to create an unencrypted sbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -S** command to create an sbspace with the option for turning logging on.

Example

The following example creates a new sbspace with transaction logging turned on. This sbspace has a size of 20 MB with an offset of 0:

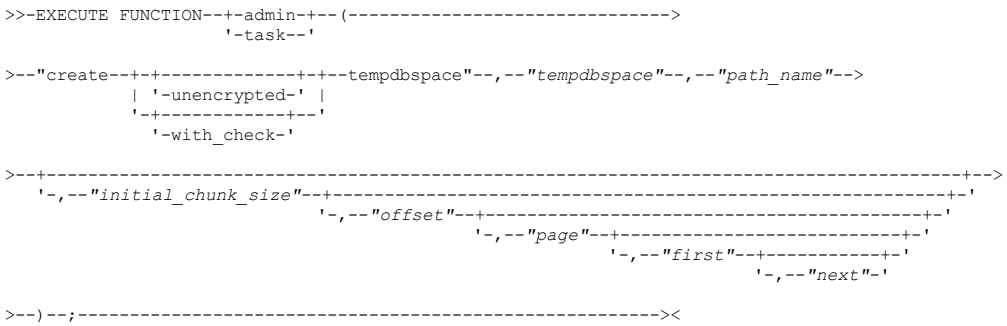
```
EXECUTE FUNCTION task ("create sbspace with log","sbspace2",
"$INFORMIXDIR/WORK/sbspace2","20 M","0");
```

Related reference:
onspaces -c -S: Create an sbspace
DISK_ENCRYPTION configuration parameter
Related information:
Sbspace logging

create tempdbspace argument: Create a temporary dbspace (SQL administration API)

Use the **create tempdbspace** argument with the **admin()** or **task()** function to create a temporary dbspace.

Syntax



Element	Description	Key Considerations
first	Size, in kilobytes, of the first extent for the tblspace **tblspace**.	See admin() and task() Argument Size Specifications.
initial_chunk_size	Size, in kilobytes, of the initial chunk of the new temporary dbspace.	See admin() and task() Argument Size Specifications.
next	Size, in kilobytes, of the next extents in the tblspace **tblspace**.	See admin() and task() Argument Size Specifications.
offset	Offset, in kilobytes, into the disk partition or into the device to reach the initial chunk of the new temporary dbspace.	See admin() and task() Argument Size Specifications
page	Non-default page size, in kilobytes, for the new temporary dbspace.	Valid page sizes depend on the default page size for the computer: • 2 KiB default page size: 2, 4, 6, 8, 10, 12, or 16 KiB • 4 KiB default page size: 4, 8, 12, or 16 KiB
path_name	Path to the disk partition or device of the initial chunk of the temporary dbspace that you are creating.	
tempdbspace	Name of the temporary dbspace to be created.	Cannot exceed 128 bytes. It must begin with a letter or underscore, and can include only letters, digits, underscore (_) symbols, or the $ character.

Usage

Use the **create with_check tempdbspace** argument to check the specified path name and return an error if the path does not exist.

Use the **create unencrypted tempdbspace** argument to create an unencrypted temporary dbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -d -t** command.

Example

The following example creates a temporary dbspace that has a size of 20 MiB with an offset of 0:

```
EXECUTE FUNCTION task("create tempdbspace","tempdbspace3",
"$INFORMIXDIR/WORK/tempdbspace3","20 M","0");
```

For the **admin()** or **task()** syntax to create a permanent dbspace from the storage pool, see create dbspace from storagepool argument: Create a dbspace from the storage pool (SQL administration API).

Related reference:
onspaces -c -d: Create a dbspace
DISK_ENCRYPTION configuration parameter

create tempdbspace from storagepool argument: Create a temporary dbspace from the storage pool (SQL administration API)

Use the create tempdbspace from storagepool argument with the **admin()** or **task()** function to create a temporary dbspace from an entry from the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--create--+-------------+--tempdbspace from storagepool--"-->
              '-unencrypted-'

>--,--"tempdbspace"--,--"initial_chunk_size"--,--+-------------+-->
                                                 '-"page_size"-'

>--)--;------------------------------------------------------><
```

Element	Description	Key Considerations
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new temporary dbspace.	See admin() and task() Argument Size Specifications.
page_size	The non-default page size, in kilobytes, for the new temporary dbspace.	The page size is optional.
tempdbspace	The name of the temporary dbspace.	

Use the **create unencrypted tempdbspace from storagepool** argument to create an unencrypted temporary dbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

Example

The following command creates a temporary dbspace named `tempdbspace1`. The new dbspace has a size of 1 gigabyte and a page size of 12 kilobytes.

```
EXECUTE FUNCTION task("create tempdbspace from storagepool", "tempdbspace1",
 "1 GB", "12");
```

Related reference:
DISK_ENCRYPTION configuration parameter

create tempsbspace argument: Create a temporary sbspace (SQL administration API)

Use the create sbspace argument with the **admin()** or **task()** function to create an sbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"create--+-+-------------+-+--tempsbspace"--,--"tempsbspace"--,--"path_name"-->
            | '-unencrypted-' |
            '-+-------------+--'
              '-with_check-'

>--+-------------------------------------------+--)--;---------><
   '-,--"initial_chunk_size"--+-------------+-'
                              '-,--"offset"-'
```

Element	Description	Key Considerations
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new temporary sbspace.	See admin() and task() Argument Size Specifications.
offset	The offset, in kilobytes, into the disk partition or into the device to reach the initial chunk of the new temporary sbspace.	
path_name	The disk partition or unbuffered device of the initial chunk of the temporary sbspace.	
tempsbspace	The name of the temporary sbspace to be created.	

Usage

Use the **create with_check tempsbspace** argument to check the specified path name and return an error if it does not exist.

Use the **create unencrypted tempsbspace** argument to create an unencrypted temporary sbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

This function is equivalent to the **onspaces -c -S** command with the **-t** option for creating a temporary sbspace.

Example

The following example creates a temporary sbspace that has a size of 20 MB with an offset of 0:

```
EXECUTE FUNCTION task ("create tempsbspace","tempsbspace3",
"$INFORMIXDIR/WORK/tempsbspace3","20 M","0");
```

Related reference:
create sbspace argument: Create an sbspace (SQL administration API)
onspaces -c -S: Create an sbspace
DISK_ENCRYPTION configuration parameter

Temporary sbspaces

create tempsbspace from storagepool argument: Create a temporary sbspace from the storage pool (SQL administration API)

Use the create tempsbspace from storagepool argument with the **admin()** or **task()** function to create a temporary sbspace from an entry from the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--create--+-------------+--tempsbspace from storagepool--"-->
              '-unencrypted-'

>--,--"tempsbspace"--,--"initial_chunk_size"--)--;------------><
```

Element	Description	Key Considerations
initial_chunk_size	The size, in kilobytes, of the initial chunk of the new sbspace.	See admin() and task() Argument Size Specifications.
tempsbspace	The name of the temporary sbspace.	The temporary sbspace name must be unique and cannot exceed 128 bytes. It must begin with a letter or underscore and must contain only letters, numbers, underscores, or the $ character.

Use the **create unencrypted tempsbspace from storagepool** argument to create an unencrypted temporary sbspace when encryption is enabled by the DISK_ENCRYPTION configuration parameter.

Example

The following command creates a temporary sbspace named `tempsbspace5`. The temporary sbspace has a size of 240 megabytes.

```
EXECUTE FUNCTION task("create tempsbspace from storagepool",
 "tempsbspace5", "240 MB");
```

Related reference:
DISK_ENCRYPTION configuration parameter

defragment argument: Dynamically defragment partition extents (SQL administration API)

Use the defragment argument with the **admin()** or **task()** function to defragment tables or indexes to merge non-contiguous extents.

Defragmenting a table brings data rows closer together to avoid partition header page overflow problems, and can improve performance.

Before you defragment a partition you should review the Partition defragmentation.

Syntax

You can specify either the `defragment` argument or `defragment partnum` argument using the following syntax:

```
>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                     '-task--'

>--(--"--defragment--"--,----"--database--:--owner--.--table--"----)--;-><
```

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                    '-task--'

                                    .-,------------------.
                                    V                    |
>--(--"--defragment partnum--"--,----partition_number--"-+--)--;-><
```

Element	Description	Key considerations
database	Name of the database that includes the table or index that you want to defragment.	
owner	User ID of the owner of the table.	
table	Name of the table to defragment.	
partition_number	One or more partition numbers to defragment.	Use a comma-separated list of partition numbers to specify more than one partition.

Usage

Use the `defragment` argument to defragment specific tables. Use the `defragment partnum` argument to defragment one or more specific disk partitions.

Information about defragmentation is stored in shared memory. Use the oncheck -pt and -pT: Display tblspaces for a Table or Fragment command to display information about the number of extents for a specific table or fragment. Use the onstat -g defragment command: Print defragment partition extents.

If the defragment request reduces the number of extents by at least 1 extent, the request returns 0 (success), even if there are many extents in the partition.

If a partition has a single extent, the defragment request returns 0 to indicate that the request was a success, even though no extents were merged.

Examples

To defragment the customer table in the `stores_demo` database, use either of the following functions:

```
EXECUTE FUNCTION task("defragment","stores_demo:informix.customer");
```

```
EXECUTE FUNCTION admin("defragment","stores_demo:informix.customer");
```

To defragment an index, you must specify the partition number for the index, as in these two function examples:

```
EXECUTE FUNCTION task("defragment partnum","2097154");
```

```
EXECUTE FUNCTION admin("defragment partnum","2097154");
```

To defragment a list of partitions, use either of the following functions:

```
EXECUTE FUNCTION task("defragment partnum", "16777217,28477346");
```

```
EXECUTE FUNCTION admin("defragment partnum", "16777217,28477346");
```

drop blobspace argument: Drop a blobspace (SQL administration API)

Use the drop blobspace argument with the **admin()** or **task()** function to drop the specified blobspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"drop blobspace"------------->
                    '-task--'

>--,--"blobspace"--)--;----------------------------------------><
```

Element	Description	Key Considerations
blobspace	The name of the blobspace to drop.	Must be an existing blobspace. Before you drop a blobspace, drop all tables that include a TEXT or BYTE column that references the blobspace.

Usage

This function is equivalent to the **onspaces -d** command.

Example

The following example drops the blobspace named **blobspace3**:

```
EXECUTE FUNCTION task("drop blobspace","blobspace3");
```

Related reference:
onspaces -d: Drop a space

drop blobspace to storagepool argument: Return space from an empty blobspace to the storage pool (SQL administration API)

Use the drop blobspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty blobspace to the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--drop blobspace to storagepool--"--,--"blobspace"--)--;--->
```

Element	Description	Key Considerations
blobspace	The name of the empty blobspace.	

Example

The following command drops an empty blobspace named `blob2` and adds all of the freed space to the storage pool.

```
EXECUTE FUNCTION task("drop blobspace to storagepool", "blob2");
```

drop chunk argument: Drop a chunk (SQL administration API)

Use the drop chunk argument with the **admin()** or **task()** function to drop the specified chunk from a dbspace, blobspace, or sbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"drop chunk"----------------->
                     '-task--'

>--,--"space_name"--+-----------------------------------+--)--;-->
                    '-,--"path_name"--,--+----------+-'
                                         '-"offset"-'
```

Element	Description	Key Considerations
offset	The offset, in kilobytes, into the disk partition or into the unbuffered device to reach the initial chunk of the dbspace, blobspace, or sbspace that you are dropping.	The starting offset, an unsigned integer, must be equal to or greater than 0. The starting offset plus the chunk size cannot exceed the maximum chunk size. The maximum offset is 4 TB. Also see admin() and task() Argument Size Specifications.
path_name	The disk partition or unbuffered device of the initial chunk of the dbspace, blobspace, or sbspace that you are dropping.	The chunk must be an existing unbuffered device or buffered file. When you specify a path name, you can use either a full path name or a relative path name. However, if you use a relative path name, it must be relative to the directory that was the current directory when you initialized the database server.
space_name	The name of the dbspace, sbspace, or blobspace from which to drop a chunk.	You can drop a chunk from a dbspace, temporary dbspace, or sbspace when the database server is online or quiescent. You can drop a chunk from a blobspace only when the database server is in quiescent mode.

Usage

This function is equivalent to the **onspaces -d** command.

Example

The following example drops a chunk at an offset of 5200 kilobytes from a dbspace named **dbspc3**:

```
EXECUTE FUNCTION task("drop chunk", "dbspc3","\\.\e:","5200");
```

Related reference:
onspaces -d: Drop a chunk in a dbspace, blobspace, or sbspace

drop chunk to storagepool argument: Return space from an empty chunk to the storage pool (SQL administration API)

Use the drop chunk to storagepool argument with the **admin()** or **task()** function to return the space from an empty chunk to the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--drop chunk to storagepool--"----------------------------->

>--,--"space_name"--,--"path_name"--,--"offset"--)--;---------><
```

Element	Description	Key Considerations
space_name	The name of the storage space in which the chunk resides.	
path_name	The path of the chunk.	
offset	The offset, in kilobytes, of the chunk.	

Example

The following command drops an empty chunk in a dbspace named `bigdbs` and adds all of the freed space to the storage pool.

```
EXECUTE FUNCTION task("drop chunk to storagepool", "bigdbs", "/dev/rawdisk23",
 "100 KB");
```

drop database argument: Drop a database (SQL administration API)

Use the drop database argument with the **admin()** or **task()** function to drop a database.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"drop database"-------------->
                     '-task--'

>--,--"database_name"--)--;------------------------------------><
```

Element	Description	Key Considerations
database_name	The name of the database.	

Usage

This function is equivalent to the DROP DATABASE statement. This function deletes the entire database, including all of the system catalog tables, objects, and data.

Example

The following example drops the database named `demodbs`:

```
EXECUTE FUNCTION task("drop database","demodbs");
```

Related information:
DROP DATABASE statement

drop dbspace argument: Drop a dbspace (SQL administration API)

Use the drop dbspace argument with the **admin()** or **task()** function to drop the specified dbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"drop dbspace"--------------->
                    '-task--'

>--,--"dbspace"--)--;---------------------------------------><
```

Element	Description	Key Considerations
dbspace	The name of the dbspace to drop.	The dbspace must exist. Before you drop a dbspace, drop all databases and tables that you previously created in the dbspace.

Usage

This function is equivalent to the **onspaces -d** command.

Example

The following example drops the dbspace named **dbspace4**:

```
EXECUTE FUNCTION task("drop dbspace","dbspace4");
```

Related reference:
onspaces -d: Drop a space

drop dbspace to storagepool argument: Return space from an empty dbspace to the storage pool (SQL administration API)

Use the drop dbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty dbspace to the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------->
                    '-task--'

>--"--drop dbspace to storagepool--"--,--"dbspace"--)--;------->
```

Element	Description	Key Considerations
dbspace	The name of the empty dbspace.	

Example

The following command drops an empty dbspace named `dbs5` and adds all of the freed space to the storage pool.

```
EXECUTE FUNCTION task("drop dbspace to storagepool", "dbs5");
```

drop log argument: Drop a logical log (SQL administration API)

Use the drop log argument with the **admin()** or **task()** function to drop the specified logical log.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"drop log"------------------->
                    '-task--'

>--,--"log_number"--)--;---------------------------------------><
```

Element	Description	Key Considerations
log_number	The logical log file number.	The number must be an unsigned integer greater than or equal to 0.

Usage

Use this function to drop a single logical log file.

The database server requires a minimum of three logical-log files at all times. You cannot drop a log file if the database server has only three logical-log files.

Important: Before you can drop any of the first three logical-log files, you must add new logical-log files and run a backup of the logical-log files. The backup must be run using either the **ontape -a** command or the **ontape -c** command. After you add the new logical-log files and run a backup, you can then use **onparams -d -l***lognum* to delete the first three logical-log files.
The status of the log file determines if the log file can be dropped, and the actions taken by the database server when the log file is dropped:

- If you drop a log file that has never been written to, status is newly Added (**A**), the database server deletes the log file and frees the space immediately.
- If you drop a used log file that has a status of User (**U**) or Free (**F**), the database server marks the log file as Deleted (**D**). After you take a level-0 backup of the dbspaces that contain the log files and the root dbspace, the database server deletes the log file and frees the space.
- You cannot drop a log file that is currently in use (**C**) or contains the last checkpoint record (**L**).

You can obtain the log number from the number field of the **onstat -l** command. The sequence of log numbers might be out of order.

This function is equivalent to the **onparams -d -l** *lognum* command.

Example

The following example drops the logical log with a file number of 2:

```
EXECUTE FUNCTION task("drop log","2");
```

The following example drops the log for a specific chunk by looking up the log number based on the chunk number:

```
SELECT task("drop log", number) FROM sysmaster:syslogfil WHERE chunk = 1;
```

Related reference:
onparams -d -l lognum: Drop a logical-log file

drop plogspace: Drop the plogspace (SQL administration API)

Use the drop plogspace argument with the **admin()** or **task()** function to drop the plogspace.

Syntax

Usage

The plogspace must be empty to be dropped. For example, if you move the physical log out of the plogspace and into a dbspace by running the **onparams -p** command, you can drop the plogspace. Alternatively, you can move the plogspace to a different chunk by creating a new plogspace. The old plogspace is removed automatically.

This function is equivalent to the **onspaces -d** command.

Example

The following example drops the plogspace:

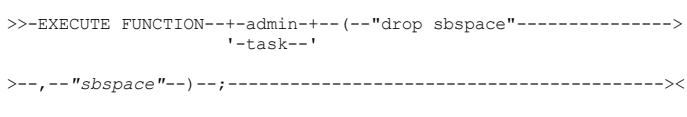
```
EXECUTE FUNCTION task("drop plogspace");
```

Related reference:
onspaces -d: Drop a chunk in a dbspace, blobspace, or sbspace

drop sbspace argument: Drop an sbspace (SQL administration API)

Use the drop sbspace argument with the **admin()** or **task()** function to drop the specified sbspace.

Syntax



Element	Description	Key Considerations

Element	Description	Key Considerations
sbspace	The name of the sbspace to drop.	The sbspace must exist. Before you drop an sbspace, drop all tables that include a BLOB or CLOB column that references the sbspace.

Usage

This function is equivalent to the **onspaces -d** command.

Example

The following example drops the sbspace named **sbspace3**:

```
EXECUTE FUNCTION task("drop dbspace","sbspace3");
```

Related reference:
onspaces -d: Drop a space

drop sbspace to storagepool argument: Return space from an empty sbspace to the storage pool (SQL administration API)

Use the drop sbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty sbspace to the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--,--"--drop sbspace to storagepool--"--"sbspace"--)--;------><
```

Element	Description	Key Considerations
sbspace	The name of the empty sbspace.	

Example

The following command drops an empty sbspace named `sbspace8` and adds all of the freed space to the storage pool.

```
EXECUTE FUNCTION task("drop sbspace to storagepool", "sbspace8");
```

drop tempdbspace argument: Drop a temporary dbspace (SQL administration API)

Use the drop tempdbspace argument with the **admin()** or **task()** function to drop the specified temporary dbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"drop tempdbspace"----------->
                     '-task--'

>--,--"tempdbspace"--)--;-------------------------------------><
```

Element	Description	Key Considerations
tempdbspace	The name of the temporary dbspace to drop.	The temporary dbspace must exist. Before you drop a temporary dbspace, drop all databases and tables that you previously created in the temporary dbspace.

Usage

This function is equivalent to the **onspaces -d** command.

Example

The following example drops the temporary dbspace named **tdbspace2**:

```
EXECUTE FUNCTION task("drop tempdbspace","tdbspace2");
```

Related reference:
onspaces -d: Drop a space

drop tempdbspace to storagepool argument: Return space from an empty temporary dbspace to the storage pool (SQL administration API)

Use the drop tempdbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty temporary dbspace to the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--drop tempdbspace to storagepool--"--,--"tempdbspace"------>

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
tempdbspace	The name of the empty temporary dbspace.	

Example

The following command drops an empty temporary dbspace named `tempdbs1` and adds all of the freed space to the storage pool.

```
EXECUTE FUNCTION task("drop tempdbspace to storagepool", "tempdbs1");
```

drop tempsbspace to storagepool argument: Return space from an empty temporary sbspace to the storage pool (SQL administration API)

Use the drop tempsbspace to storagepool argument with the **admin()** or **task()** function to return the space from an empty temporary sbspace to the storage pool.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--drop tempsbspace to storagepool--"--,--"tempsbspace"------>

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
tempsbspace	The name of the empty temporary sbspace.	

Example

The following command drops an empty temporary sbspace named `tempsbspace3` and adds all of the freed space to the storage pool.

```
EXECUTE FUNCTION task("drop tempsbspace to storagepool", "tempsbspace3");
```

export config argument: Export configuration parameter values (SQL administration API)

Use the export config argument with the **admin()** or **task()** function to export a file that contains all configuration parameters and their current values.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"--export config--"---------->
                     '-task--'

>--,--"file_path"--)--;-----------------------------------------><
```

Table 1. **export config** command elements

Element	Description	Key Considerations
file_path	Full path name for the file	Do not add an extension.

Usage

The SQL administration API export command automatically creates an ASCII file, assigning it the name that you specified in the command. The format of the file is the same as the format of the onconfig.std file.

You must specify the full path name. You cannot specify a relative path.

This command is the equivalent of the **onmode –we** commend.

Example

The following command exports all configuration parameters and their current values to a file named `cfg_12` in the `/tmp` directory:

```
EXECUTE FUNCTION task("export config", "/tmp/cfg_12");
```

Related tasks:
Modifying the onconfig file
Related reference:
import config argument: Import configuration parameter values (SQL administration API)
onmode -we: Export a file that contains current configuration parameters

file status argument: Display the status of a message log file (SQL administration API)

Use the file status argument with the **admin()** or **task()** function to specify the status of an online, ON-Bar activity, or ON-Bar debug message log file.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                     '-task--'

>--(--"file status"--,--"--file_path--"--)--;------------------><
```

Element	Purpose	Key considerations
file_path	Full path name for the online, ON-Bar activity, or ON-Bar debug message log file.	

Example

The following example shows the argument that you can use to display the status of the /usr/informix/online.log file:

```
execute function task("file status", "/usr/informix/online.log");
```

The server then displays information such as:

```
(expression)  File name          = /tmp/x
              Is File            = 1
              Is Directory       = 0
              Is Raw Device      = 0
              Is Block Device    = 0
              Is Pipe            = 0
              File Size          = 554
              Last Access Time   = 11/29/2010 21:55:02
              Last Modified Time = 11/29/2010 21:51:45
              Status Change Time = 11/29/2010 21:51:45
              User Id            = 200
              Group id           = 102
              File Flags         = 33206
```

Related reference:
message log rotate argument: Rotate the message log file (SQL administration API)
message log truncate argument: Delete the contents of a message log file (SQL administration API)
message log delete argument: Delete a message log file (SQL administration API)

grant admin argument: Grant privileges to run SQL administration API commands

Use the grant admin argument with the **admin()** or **task()** function to grant privileges to run SQL administration API commands.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"--grant admin--"------------>
                    '-task--'

>--,--"--user_name--"--,--"--privilege_group--"--)--;---------><
```

Element	Description	Key Considerations
user_name	The name of the user for which privileges are granted.	
privilege_group	The name of the privilege group.	See SQL administration API portal: Arguments by privilege groups for a list of privilege groups.

Usage

Individual users can be granted privileges to administer their database servers by running SQL administration API commands. Users with these privileges can connect to a database server with their user name and run SQL administration API commands, by connecting directly.

Only user **informix**, or a user with ADMIN or GRANT privilege for SQL administration API commands, can use the **grant admin** argument.

Example

The following command grants the privilege for running backup and restore SQL administration commands to the user Bob:

```
EXECUTE FUNCTION task("grant admin", "Bob", "BAR");
```

Related reference:
DBCREATE_PERMISSION configuration parameter

ha make primary argument: Change the mode of a secondary server (SQL administration API)

Use the ha make primary argument with the **admin()** or **task()** function to change the specified secondary server to a primary or standard server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                    '-task--'

>--+-"ha make primary"-------+--,--"database_server"--)--;----->
   '-"ha make primary force"-'
```

Element	Description	Key Considerations
database_server	The name of the database server.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

This function has different results depending on the type of secondary server:

- HDR Secondary: The current primary server is shut down and the HDR secondary server is made the primary server.
- RS secondary: The RS secondary server is changed to a standard server.
- SD secondary: The SD secondary server is made the new primary server.

Use the ha make primary argument to change an inactive secondary server to a primary server when there is an active connection between them.

Use the ha make primary force argument to change an inactive secondary server to a primary server, whether or not a secondary server is connected to it. If the connection is active, the function succeeds, however, if you run the function with the force argument on an SD secondary server, the shared disk subsystem can become corrupted.

This function is equivalent to the **onmode -d make primary** command.

Example

The following example converts an HDR secondary server named **ids_stores2** into a primary server:

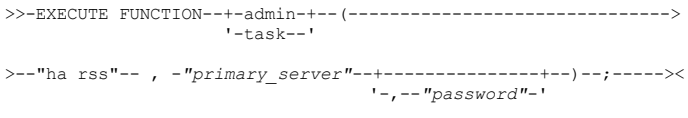
```
EXECUTE FUNCTION task("ha make primary","ids_stores2");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha rss argument: Create an RS secondary server (SQL administration API)

Use the ha rss argument with the **admin()** or **task()** function to create a remote standalone (RS) secondary server.

Syntax



Element	Description	Key Considerations
password	A password to set or to change.	The password is used only during the first connection attempt. After the primary and secondary server have connected, the password cannot be changed.
primary_server	The name of the primary database server.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function on a standard server or a quiescent HDR secondary server to convert it an RS secondary server.

This function is equivalent to the **onmode -d RSS** command.

Example

The following example converts a standard server into an RS secondary server with a primary server named **ids_stores**:

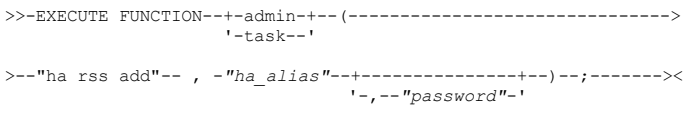
```
EXECUTE FUNCTION task("ha rss","ids_stores");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha rss add argument: Add an RS secondary server to a primary server (SQL administration API)

Use the ha rss add argument with the **admin()** or **task()** function to associate a primary server with a remote standalone (RS) secondary server.

Syntax



Element	Description	Key Considerations
password	The password to set or to change.	The password is used only during the first connection attempt. After the primary and secondary server have connected, the password cannot be changed.

Element	Description	Key Considerations
ha_alias	The high-availability alias of the database server to convert to an RS secondary server.	The name must be defined in the HA_ALIAS configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function from an established primary server to create an RS secondary server and register the RS secondary server name in the **sysha** database.

This function is equivalent to the **onmode -d add RSS** command.

Example

The following example associates a server with a high-availability alias of **ids_stores2** as an RS secondary server to the primary server:

```
EXECUTE FUNCTION task("ha rss add","ids_stores2");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha rss change argument: Change the password of an RS secondary server (SQL administration API)

Use the ha rss change argument with the **admin()** or **task()** function to change the connection password for the specified RS secondary server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"ha rss change"--,--"secondary_server"-- , -"password"------->

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
password	The password to set or to change.	The password is used only during the first connection attempt. After the primary and secondary server have connected, the password cannot be changed.
secondary_server	The name of the database server to convert to an RS secondary server.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function on an established primary server to change the password for the connection between the primary and secondary server.

This function is equivalent to the **onmode -d change RSS** command.

Example

The following example changes the password for the RS secondary server to `secure`:

```
EXECUTE FUNCTION task("ha rss change","ids_stores2","secure");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha rss delete argument: Delete an RS secondary server (SQL administration API)

Use the ha rss delete argument with the **admin()** or **task()** function to stop replication and delete the RS secondary server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'
```

```
>--"ha rss delete"--,--"secondary_server"--)--;---------------><
```

Element	Description	Key Considerations
secondary_server	The name of the database server to convert to an RS secondary server.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function from an established primary server to convert the RS secondary server to a standard server and delete the RS secondary server.

This function is equivalent to the **onmode -d delete RSS** command.

Example

The following example deletes the RS secondary server named **ids_stores2**:

```
EXECUTE FUNCTION task("ha rss delete","ids_stores2");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha sds clear argument: Stop shared-disk replication (SQL administration API)

Use the ha sds clear argument with the **admin()** or **task()** function to stop replication to shared disk (SD) secondary servers and convert the primary server to a standard server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"ha sds clear"--,--"primary_server"--)--;------------------><
```

Element	Description	Key Considerations
primary_server	The name of the primary server to convert to a standard server.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function on an established primary server to stop replication to the SD secondary servers.

This function is equivalent to the **onmode -d clear SDS primary** command.

Example

The following example stops replication from the primary server named **ids_stores** to SD secondary servers:

```
EXECUTE FUNCTION task("ha sds clear","ids_stores");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha sds primary argument: Convert an SD secondary server to a primary server (SQL administration API)

Use the ha sds primary argument with the **admin()** or **task()** function to change a shared disk (SD) secondary server to a primary server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"ha sds primary"-------+--->
                     '-task--'     '-"ha sds primary force"-'
```

```
>--,--"secondary_server"--)--;--------------------------------><
```

Element	Description	Key Considerations
secondary_server	The name of the SD secondary server to set as a primary server.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function on an established SD secondary server to convert it to the primary server.

Use the ha sds primary argument to convert an inactive SD secondary server to a primary server, if the SD secondary servers are connected to it.

Use the ha sds primary force argument to convert an inactive SD secondary server to a primary server, whether or not any SD secondary servers are connected to it. If sessions are active, the call succeeds, but the shared disk subsystem can become corrupted.

This function is equivalent to the **onmode -d make primary** command.

Example

The following example converts an SD secondary server named **ids_stores3** to the primary server:

```
EXECUTE FUNCTION task("ha sds primary","ids_stores3");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha sds set argument: Create a shared-disk primary server (SQL administration API)

Use the ha sds set argument with the **admin()** or **task()** function to define a primary server to replicate to shared disk (SD) secondary servers.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"ha sds set"-------+------->
                     '-task--'     '-"ha sds set force"-'

>--,--"primary_server"--)--;-----------------------------------><
```

Element	Description	Key Considerations
primary_server	The name of the database server to set as a primary server.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function on a standard server to define it as a primary server for SD secondary servers.

Use the ha sds set argument to define an inactive standard server as a primary server, if the SD secondary servers are connected to it.

Use the ha sds set force argument to define an inactive standard server as a primary server, whether or not any SD secondary servers are connected to it. If sessions are active, the call succeeds, but the shared disk subsystem can become corrupted.

This function is equivalent to the **onmode -d set SDS primary** command.

Example

The following example converts a standard server named **ids_stores** to a primary server:

```
EXECUTE FUNCTION task("ha sds set","ids_stores");
```

Related reference:
onmode -d: Set High Availability server characteristics

ha set idxauto argument: Replicate indexes to secondary servers (SQL administration API)

Use the ha set idxauto argument with the **admin()** or **task()** function to control whether indexes are automatically replicated to secondary servers.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"ha set idxauto off"-+----->
                     '-task--'     '-"ha set idxauto on"--'

>--)--;-------------------------------------------------------><
```

Usage

Run this function on an established primary server to enable or disable automatic index replication to secondary servers.

You can run this function on any type of primary server.

This function is equivalent to the **onmode -d idxauto** command.

Example

The following example enables automatic index replication:

```
EXECUTE FUNCTION task("ha set idxauto on");
```

Related reference:
onmode -d command: Replicate an index with data-replication

ha set ipl argument: Log index builds on the primary server (SQL administration API)

Use the ha set ipl argument with the **admin()** or **task()** function to control whether to log index builds on the primary server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"ha set ipl off"-+--)--;-->
                     '-task--'     '-"ha set ipl on"--'
```

Usage

Run this function on an established primary server to enable or disable the logging of index builds. This function resets the value of the LOG_INDEX_BUILDS configuration parameter in the ONCONFIG file.

You can run this function on any type of primary server.

This function is equivalent to the **onmode -wf LOG_INDEX_BUILDS** command.

Example

The following example enables the logging of index builds:

```
EXECUTE FUNCTION task("ha set ipl on");
```

Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters

ha set primary argument: Define an HDR primary server (SQL administration API)

Use the ha set primary argument with the **admin()** or **task()** function to define a High-Availability Data Replication (HDR) primary server and specify the secondary server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"ha set primary"--,--"secondary_server"--)--;--------------><
```

Element	Description	Key Considerations

Element	Description	Key Considerations
secondary_server	The name of the HDR secondary server to connect to.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function on a standard server to convert it to an HDR primary server and connect to the specified HDR secondary server. If the connection is successful, replication begins.

This function is equivalent to the **onmode -d primary** command.

Example

The following example converts a standard server named **ids_stores** to an HDR primary server:

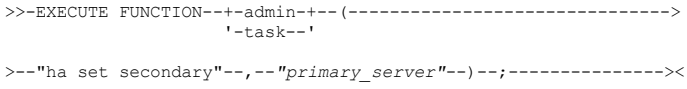
```
EXECUTE FUNCTION task("ha set primary","ids_stores");
```

Related reference:
onmode -d: Set data-replication types

ha set secondary argument: Define an HDR secondary server (SQL administration API)

Use the ha set secondary argument with the **admin()** or **task()** function to define a High-Availability Data Replication (HDR) secondary server and specify the primary server.

Syntax



Element	Description	Key Considerations
primary_server	The name of the HDR primary server to connect to.	The name must be defined in the DBSERVERNAME or DBSERVERALIASES configuration parameter, or as an Enterprise Replication group name.

Usage

Run this function on a standard database server to convert it to an HDR secondary server, and connect to the specified primary server. If the connection is successful, replication begins.

This function is equivalent to the **onmode -d secondary** command.

Example

The following example converts a standard server to an HDR secondary server, with a primary server named **ids_stores**:

```
EXECUTE FUNCTION task("ha set secondary","ids_stores");
```

Related reference:
onmode -d: Set data-replication types

ha set standard argument: Convert an HDR server into a standard server (SQL administration API)

Use the **ha set standard** argument with the **admin()** or **task()** function to convert a High-Availability Data Replication (HDR) primary or secondary server to a standard server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"ha set standard"--)--;----->
                    '-task--'
```

Usage

Run this function on a HDR primary or secondary server to convert it to a standard server. The connection between the primary and secondary servers is dropped and replication stops. The mode of the other server in the HDR pair is not changed.

This function is equivalent to the **onmode -d standard** command.

Example

The following example converts an HDR secondary server to a standard server:

```
EXECUTE FUNCTION task("ha set standard");
```

Related reference:
onmode -d: Set data-replication types

ha set timeout argument: Change SD secondary server timeout (SQL administration API)

Use the ha set timeout argument with the **admin()** or **task()** function to change the amount of time in seconds that the primary server waits for acknowledgments from shared disk (SD) secondary servers.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                    '-task--'

>--"ha set timeout"--,--"seconds"--)--;------------------------><
```

Element	Description	Key Considerations
seconds	The number of seconds the primary server waits before disconnecting the SD secondary server.	The value must be a positive integer in the range: • from 2 • to 2 147 483 647

Usage

Run this function on an established shared disk primary server to specify the amount of time in seconds that the primary server waits for a log position acknowledgment to be sent from an SD secondary server. If there is no log position acknowledgment received from the SD secondary server in the specified amount of time, the primary server disconnects from the SD secondary server and continues. After waiting for the specified number of seconds, the primary server starts removing SD secondary servers if page flushing has timed out while waiting for an SD secondary server.

This function resets the value of the SDS_TIMEOUT configuration parameter in the ONCONFIG file.

This function is equivalent to the **onmode -wf SDS_TIMEOUT** command.

Example

The following example sets the timeout period to 5 seconds:

```
EXECUTE FUNCTION task("ha set timeout","5");
```

Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters

import config argument: Import configuration parameter values (SQL administration API)

Use the import config argument with the **admin()** or **task()** function to import a file that contains one or more dynamically updatable configuration parameters and apply the new values.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"--import config--"---------->
                     '-task--'

>--,--"file_path"--)--;---------------------------------------><
```

Table 1. import config command elements

Element	Description	Key Considerations
file_path	The full path name of the previously exported file that contains the names and values of one or more dynamically updatable configuration parameters	

Usage

Dynamically updatable configuration parameters are those parameters that you can change for a session with an **onmode -wf** or **onmode -wm** command.

You must specify the full path name. You cannot specify a relative path.

This command is the equivalent of the **onmode –wi** commend.

Example

The following command imports a file named `cfg_12` in the `/tmp` directory:

```
EXECUTE FUNCTION task("import config", "/tmp/cfg_12");
```

Related tasks:
Modifying the onconfig file
Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters
export config argument: Export configuration parameter values (SQL administration API)
onmode -wi: Import a configuration parameter file

index compress repack shrink arguments: Optimize the storage of B-tree indexes (SQL administration API)

Use the index compress repack shrink argument with the **admin()** or **task()** function to compress detached B-tree indexes, consolidate free space (repack), and return free space (shrink) in partitions.

Syntax: Index compression command arguments

```
>>-EXECUTE FUNCTION--+-admin-+--(--"--index--------------------->
                     '-task--'

>--+-compress--+--------+--+--------+--+----------+-+--"-------->
   |           '-repack-'  '-shrink-'  '-parallel-' |
   +-repack--+--------+--+----------+---------------+
   |         '-shrink-'  '-parallel-'               |
   '-shrink----------------------------------------'

>--,--"index_name"--,--"database_name"--,--"owner"--)--;------->
```

Command arguments

The following table contains a brief explanation of each argument.

Table 1. Arguments for index compression operations

Argument	Description
compress	Compresses the index.
parallel	Runs the compress or repack operation in parallel. A thread is started for each fragment of the table or fragment list and the operation is run in parallel across those fragments.
repack	Consolidates free space by moving data to the front of the index.
shrink	Returns free space at the end of the index to the dbspace, thus reducing the total size of the index.

Command elements

The following table shows the elements that you can use to compress, repack, and shrink indexes.

Table 2. Index compress command elements

Element	Description	Key Considerations
index_name	The name of the index that you want to compress.	Required. You must use the same uppercase or lowercase letters that are in system catalog tables.
database_name	The name of the database that contains the index that you want to compress.	Optional. If you do not specify a database, the database server uses the current database. If you enter a database name, you must use the same uppercase or lowercase letters that are in system catalog tables.
owner	The name of the owner of the database that contains the index that you want to compress.	Optional. If you do not specify an owner, the database server uses the current owner. If you enter an owner name, you must use the same uppercase or lowercase letters that are in system catalog tables.

Usage

You can compress a detached B-tree index that is on a fragmented or non-fragmented table. You cannot compress an attached index.

To be compressed, an index must have at least 2000 keys. If a fragment within the index does not have at least 2000 keys, the database server does not compress the index or fragment when it creates the index. The index remains uncompressed even if new keys are added to it. If you want to compress the index, run another SQL Admin API **task()** or **admin()** function with the index compress argument.

To determine if an index contains the minimum number of keys, run the **oncheck -pT** command and view information in the Number of keys field.

Typically you perform a repack operation after a compress operation and the shrink after a repack operation.

The compression operation compresses only the leaves (bottom level) of the index.

You can cancel a command, for example, by typing CTRL-C in DB-Access.

You cannot uncompress an index. If you want an uncompressed index, you can drop the compressed index and recreate it.

Example

The following command compresses, repacks, and shrinks an index in parallel.

```
EXECUTE FUNCTION task("index compress repack shrink parallel",
"ind5", "customer", "jayson");
```

index estimate_compression argument: Estimate index compression (SQL administration API)

Use the index estimate_compression argument with the **admin()** or **task()** function to estimate if you can save disk space by compressing a B-tree index.

```
Syntax: index estimate_compression command argument

>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                     '-task--'

>--(--"--index estimate_compression--"-------------------------->

>--,--"index_name"--,--"database_name"--,--"owner"--)--;------><
```

Command elements

The following table shows the elements that you can use to estimate index compression.

Table 1. Index estimate_compression command elements

Element	Description	Key Considerations
index_name	The name of the index for which you want to estimate compression benefits.	Required. You must use the same uppercase or lowercase letters that are in system catalog tables.
database_name	The name of the database that contains the index.	Optional. If you do not specify a database, the database server uses the current database. If you enter a database name, you must use the same uppercase or lowercase letters that are in system catalog tables.

Element	Description	Key Considerations
owner	The name of the owner of the database that contains the index.	Optional for an index. If you do not specify an owner, the database server uses the current owner. If you enter an owner name, you must use the same uppercase or lowercase letters that are in system catalog tables.

Usage

You can estimate compression only for a detached B-tree index on a fragmented or non-fragmented table.

The estimate compression operation displays the name of the index, the estimated compression ratio that can be achieved, the current compression ratio, and an estimate of the percentage gain or loss. The current ratio is 0.0 percent if the index is not compressed.

Example

The following command estimates compression benefits for an index named **ind4** in the **customer** database for which **anjul** is the owner.

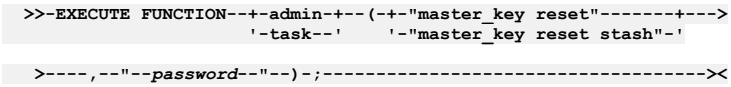
```
EXECUTE FUNCTION task("index estimate_compression","ind4",
"customer","anjul");
```

Related reference:
Output of the estimate compression operation (SQL administration API)

master_key reset argument: Change the keystore password (SQL administration API)

Use the master_key reset argument with the **admin()** or **task()** function to change the password for the storage space encryption keystore. The password is used to encrypt the keystore for storage space encryption.

Syntax



Element	Purpose	Key considerations
password	A password that you supply for the storage space encryption keystore.	The maximum length is 32 bytes and the minimum length is 8 bytes.

Usage

You must be logged in as user **informix** or the root user to run this command.

The password protects the storage space encryption keystore. You can run the **admin()** or **task()** function with the **master_key reset** argument at any time to change the password. The keystore gets encrypted with the new password. The optional keyword "stash" enforces the stashing of the new password even if the old password was not stashed before.

Example

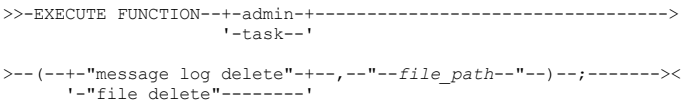
The following example shows how to change the password:

```
execute function task("master_key reset", "This is my new password");
```

message log delete argument: Delete a message log file (SQL administration API)

Use the message log delete argument or file delete argument with the **admin()** or **task()** function to specify the particular online, ON-Bar activity, or ON-Bar debug message log to delete.

Syntax



Element	Purpose	Key considerations
file_path	Full path name for the particular online, ON-Bar activity, or ON-Bar debug message log file.	

Examples

The following examples show the arguments that you can use to delete the /usr/informix/online.log file:

```
execute function task("message log delete", "/usr/informix/online.log");
```

```
execute function task("file delete", "/usr/informix/online.log");
```

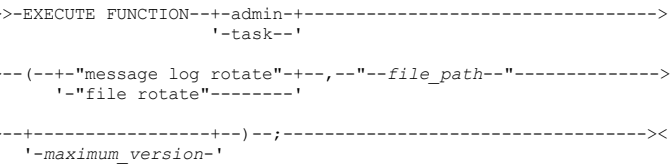
Related reference:
message log rotate argument: Rotate the message log file (SQL administration API)
message log truncate argument: Delete the contents of a message log file (SQL administration API)
file status argument: Display the status of a message log file (SQL administration API)

message log rotate argument: Rotate the message log file (SQL administration API)

Use the message log rotate argument or the file rotate argument with the **admin()** or **task()** function to specify the particular online, ON-Bar activity, or ON-Bar debug message log file to rotate, and to indicate the maximum number of message logs to rotate.

When the message log file rotates, the database server switches to a new online message log file and increments the ID numbers for the previous log files by one. When the maximum number of log files is reached, the log file with the highest ID is deleted.

Syntax



Element	Purpose	Key considerations
file_path	Full path name of the online, ON-Bar activity, or ON-Bar debug message log file that the server will rotate, for example, /usr/informix/online.log.	
maximum_version	The log file with the highest ID. This is the maximum message log version that the server will rotate.	

Examples

The following examples show the arguments that you can use to rotate a maximum of 52 /usr/informix/online.log files:

```
execute function task("message log rotate", "/usr/informix/online.log",52);
```

```
execute function task("file rotate", "/usr/informix/online.log",52);
```

When the database server rotates these files, the server deletes version 52 of the file. Version 51 becomes version 52, version 50 becomes version 51, and so on. The new online log becomes version 1.

Related reference:
message log truncate argument: Delete the contents of a message log file (SQL administration API)
message log delete argument: Delete a message log file (SQL administration API)
file status argument: Display the status of a message log file (SQL administration API)

message log truncate argument: Delete the contents of a message log file (SQL administration API)

Use the message log truncate argument or file truncate argument with the **admin()** or **task()** function to specify the particular online, ON-Bar activity, or ON-Bar debug message log file to truncate. When the database server truncates a message log file, it deletes the messages in the log file, but keeps the log file.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                    '-task--'

>--(--+-"message log truncate"-+--,--"--file_path--"--)--;----->< 
      '-"file truncate"--------'
```

Element	Purpose	Key considerations
file_path	Full path name for the online, ON-Bar activity, or ON-Bar debug message log file.	

Examples

The following examples show the arguments that you can use to truncate the /usr/informix/online.log file:

```
execute function task("message log truncate", "/usr/informix/online.log");
```

```
execute function task("file truncate", "/usr/informix/online.log");
```

Related reference:
message log rotate argument: Rotate the message log file (SQL administration API)
message log delete argument: Delete a message log file (SQL administration API)
file status argument: Display the status of a message log file (SQL administration API)

modify chunk extend argument: Extend the size of a chunk (SQL administration API)

Use the modify chunk extend argument with the **admin()** or **task()** function to extend the size of the chunk by a specified minimum amount. The chunk must be marked as extendable.

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                    '-task--'

>--(--"--modify chunk extend--"--,--"chunk_number"--,--"extend_amount"--)-- ;-><
```

Element	Description	Key Considerations
chunk_number	The number of the chunk.	
extend_amount	The minimum amount of space in kilobytes to add to the chunk.	See admin() and task() Argument Size Specifications.

Usage

You must mark a chunk as extendable before the chunk can be extended, either manually or automatically. Use the modify chunk extendable argument with the **admin()** or **task()** function to mark a chunk as extendable.

The **modify chunk extend** SQL administration API command is an alternative to the **adm_add_storage** task that the server can run to automatically extend the size of a chunk when the space containing the chunk runs low or out of free pages.

You cannot extend a chunk in a mirrored space, and you will receive an error if you provide the number of a mirror chunk when you run a **modify chunk extend** SQL administration API command.

To identify primary and mirror chunks in a mirrored space, look for the `P` (primary) or `M` (mirror) in position 1 of the `flags` field in **onstat -d** command output.

The server might round up the requested size, depending on the page size and the configured create size and extend size of the space.

Examples

Suppose that your **onstat -d** command output shows that chunk number 3 is a mirror chunk and chunk number 4 is a not a mirror chunk. You cannot extend the size of chunk number 3. However, you can modify chunk number 4. The following command extends the size of chunk number 4 by 10000 kilobytes:

```
EXECUTE FUNCTION task("modify chunk extend", "4", "10000");
```

Related reference:
modify chunk extendable argument: Mark a chunk as extendable (SQL administration API)
modify chunk extend argument: Extend the size of a chunk (SQL administration API)
modify space sp_sizes argument: Modify sizes of an extendable storage space (SQL administration API)
modify space expand argument: Expand the size of a space (SQL administration API)
onstat -d command: Print chunk information

modify chunk extendable argument: Mark a chunk as extendable (SQL administration API)

Use the modify chunk extendable argument with the **admin()** or **task()** function to specify that a particular chunk in an unmirrored dbspace or temporary dbspace can be extended..

```
>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                     '-task--'

>--(--"--modify chunk extendable--"--,--"--chunk_number--"--)-- ;-><
```

Element	Description	Key Considerations
chunk_number	The number of the chunk.	

Usage

If a chunk is marked as extendable, either:

- The server can automatically extend the chunk when the unmirrored dbspace or temporary dbspace containing the chunk runs low or out of free pages.
- You can use the modify chunk extend argument with the **admin()** or **task()** function to extend the size of the chunk.

However, if the extend size for the dbspace or temporary dbspace is set to `0`, the server cannot automatically extend an extendable chunk in that space. In this situation, you can still manually extend the chunk.

The server will automatically mark chunks that are allocated from extendable storage pool entries as extendable. Therefore, you do not need to mark these chunks as extendable. For information on extendable storage pool entries, see storagepool add argument: Add a storage pool entry (SQL administration API).

Chunks in mirrored spaces cannot be extended. If you try to make a mirror chunk extendable, you will receive an error.

To identify primary and mirror chunks in a mirrored space, look for the `P` (primary) or `M` (mirror) in position 1 of the `flags` field in **onstat -d** command output.

Example

The following snippet of **onstat -d** output shows that chunk number 3 is a mirror chunk:

```
Chunks
address      chunk/dbs  offset   size     free     bpages   flags pathname
451191c8     1      1   0        225000   101572           PO-B-- /reg1/rootchunk
451197d0     2      2   0        1250     1149             PO-B-- /reg1/dbs1
451199d0     3      3   0        1250     1149             PO-B-- /reg1/dbs2
46a36638     3      3   0        1250     0                MO-B-- /reg1/chunk2
45119bd0     4      4   0        1250     1149             PO-B-- /reg1/dbs3
```

Thus, you cannot extend the size of chunk number 3. However, you can specify that chunk number 4 is extendable, as follows:

```
EXECUTE FUNCTION sysadmin:task("modify chunk extendable", "4");
```

Related reference:
modify chunk extendable off argument: Mark a chunk as not extendable (SQL administration API)
modify space sp_sizes argument: Modify sizes of an extendable storage space (SQL administration API)
modify chunk extend argument: Extend the size of a chunk (SQL administration API)
modify space expand argument: Expand the size of a space (SQL administration API)

modify chunk extendable off argument: Mark a chunk as not extendable (SQL administration API)

Use the modify chunk extendable off argument with the **admin()** or **task()** function to specify that a particular chunk cannot be extended.

```
>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                     '-task--'

>--(--"--modify chunk extendable off--"--,--"--chunk_number--"--)-- ;-><
```

Element	Description	Key Considerations
chunk_number	The number of the chunk.	

Usage

The default status for chunks is not extendable. If you previously marked a chunk as extendable, you can change the status to not extendable.

If a chunk is marked as not extendable:

- The server cannot automatically extend the chunk when the space containing the chunk runs low or out of free pages.
- You cannot manually extend the size of the chunk.

If the storage pool contains entries, the server can extend a storage space by adding another chunk to the storage space.

Example

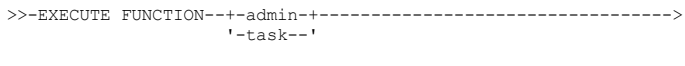
The following example specifies that the you or the server cannot extend chunk 9:

```
EXECUTE FUNCTION task("modify chunk extendable off", "9");
```

Related reference:
modify chunk extendable argument: Mark a chunk as extendable (SQL administration API)

modify chunk swap_mirror argument: Switch primary and mirror chunk files without any downtime(SQL administration API)

Use the modify chunk swap_mirror argument with the **admin()** or **task()** function to easily migrate data from old disk drives to new ones without downtime.



Element	Description	Key Considerations
chunk_number	The number of the chunk.	The chunk must be mirrored. Both the primary and the mirror chunk must be on-line.

Usage

To migrate data in a chunk from one disk drive to another on the fly, do the following:

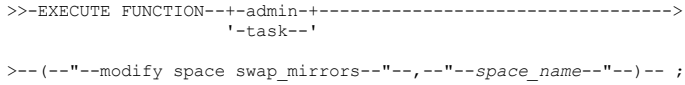
1. Add a mirror chunk to the original, primary chunk, placing the mirror on the new disk drive.
   Note: All chunks in a mirrored space must be mirrored.
   For more information see, **onspaces -m** or **add mirror** SQL administration API command.
2. Swap the primary chunk and the mirror using the **modify chunk swap_mirror** command.
3. Drop the mirror chunk (the original primary) by turning off mirroring for the space. For more information see, **onspaces -r** or **stop mirroring** SQL administration API command.

Example

```
EXECUTE FUNCTION sysadmin:task("create dbspace","newdbs","/prod1/IFX_CHUNKS/chunk5",10000,0);
EXECUTE FUNCTION sysadmin:task("add mirror","newdbs","/prod1/IFX_CHUNKS/chunk5",0,"/prod8/IFX_CHUNKS/chunk1",0);
select chknum from sysmaster:syschunks where fname = "/prod1/IFX_CHUNKS/chunk5";
EXECUTE FUNCTION sysadmin:task("modify chunk swap_mirror", "12");
EXECUTE FUNCTION sysadmin:task("stop mirroring","newdbs");
```

modify space swap_mirror argument: Switch all primary and mirror chunk files for a space without any downtime (SQL administration API)

Use the modify space swap_mirrors argument with the **admin()** or **task()** function to easily migrate data from old disk drives to new ones without downtime.



Element	Description	Key Considerations
space_name	The name of the storage space	The space must be mirrored. All primary and mirror chunks in the space must be on-line.

Usage

To migrate data in a chunk from one disk drive to another without any downtime, do the following:

1. Add mirror chunks to the original, primary chunks using the **onspaces -m** command, placing the mirrors on the new disk drive.
   Note: All chunks in a mirrored space must be mirrored.
2. Swap the primary chunks and the mirrors using the **modify space swap_mirrors** command.
3. Drop the mirror chunks (the original primary) by turning off mirroring for the space. For more information see, **onspaces -r** or **stop mirroring** SQL administration API command.

Example

```
EXECUTE FUNCTION sysadmin:task("create dbspace","newdbs","/prod1/IFX_CHUNKS/chunk5",10000,0);
EXECUTE FUNCTION sysadmin:task("add chunk","newdbs","/prod1/IFX_CHUNKS/chunk6",10000,0);
onspaces -m newdbs -p /prod1/IFX_CHUNKS/chunk5 -o 0 -m /prod8/IFX_CHUNKS/chunk1 0 -p /prod1/IFX_CHUNKS/chunk6 -o 0 -m
/prod8/IFX_CHUNKS/chunk2 0 -y
EXECUTE FUNCTION sysadmin:task("modify space swap_mirrors", "newdbs");
EXECUTE FUNCTION sysadmin:task("stop mirroring","newdbs");
```

modify config arguments: Modify configuration parameters (SQL administration API)

Use the modify config argument with the **admin()** or **task()** function to change the value of a configuration parameter in memory until you restart the database server. Use the modify config persistent argument to change the value of a configuration parameter in memory and preserve the value in the onconfig file after you restart the server.

Syntax

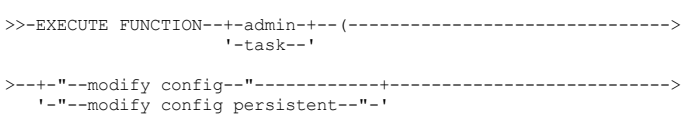


Table 1. modify config command elements

Element	Description	Key Considerations
configuration_parameter_name	The name of the configuration parameter that you want to modify.	
new_value	The new value of the configuration parameter.	For information about the valid values for a configuration parameter, see Database configuration parameters.

Usage

This SQL administration API command is equivalent to using an **onmode -wm** or **-wf** command to change the value of a configuration parameter.

Examples

The following command changes the value of the DYNAMIC_LOGS configuration parameter to 2 in memory for current use:

```
EXECUTE FUNCTION task("modify config","DYNAMIC_LOGS",
"2");
```

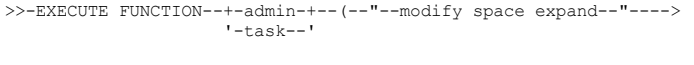
The following command changes the value of the DYNAMIC_LOGS configuration parameter for current use. The changed value remains in the onconfig file after you restart the server.

```
EXECUTE FUNCTION task("modify config persistent","DYNAMIC_LOGS",
"2");
```

Related tasks:
Modifying the onconfig file
Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters

modify space expand argument: Expand the size of a space (SQL administration API)

Use the modify space expand argument with the **admin()** or **task()** function to immediately expand the size of a space, when you do not want to wait for Informix® to automatically expand the space.



```
>--,--"space_name"--,--"minimum_size"--)--;--------------------><
```

Element	Description	Key Considerations
space_name	The name of the storage space.	
minimum_size	The minimum size by which you want to expand the space.	See admin() and task() Argument Size Specifications.

Usage

The modify space expand SQL administration API command expands a storage space immediately, either by extending an extendable chunk in the space or by adding a new chunk. The create size and extend size settings for the space do not affect this operation.

The actual number of kilobytes added to the space might exceed your requested size, depending on factors such as the page size of the space and the chunk size settings for available entries in the storage pool.

The storage pool must contain entries (such as raw devices, cooked files, or directories) that the server can use to expand the space.

After you run a modify space expand SQL administration API command, Informix first attempts to expand the space by extending an extendable chunk in the space. If the space does not contain any extendable chunks, the server uses entries in the storage pool to expand the space.

You cannot expand a mirrored storage space.

Examples

The following command expands `dbspace5` by 10 megabytes:

```
EXECUTE FUNCTION task("modify space expand", "dbspace5", "10 MB");
```

Related reference:
modify chunk extendable argument: Mark a chunk as extendable (SQL administration API)
modify chunk extend argument: Extend the size of a chunk (SQL administration API)
modify space sp_sizes argument: Modify sizes of an extendable storage space (SQL administration API)
create chunk from storagepool argument: Create a chunk from the storage pool (SQL administration API)

modify space sp_sizes argument: Modify sizes of an extendable storage space (SQL administration API)

Use the modify space sp_sizes argument with the **admin()** or **task()** function to modify the create, extend, and maximum sizes that are associated with expanding a storage space. Modify the sizes to control how Informix® uses storage pool entries for a particular storage space.

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--modify space sp_sizes--"--,--"--space_name--"------------->

>--,--"--new_create_size--"--,--"--new_extend_size--"----------->

>--+-------------------+--)--;--------------------------------><
   '-,--"--max_size--"-'
```

Element	Description	Key Considerations
space_name	The name of the storage space.	
max_size	The maximum size of the storage space, in KB.	The default maximum size is 0, which indicates unlimited size.
new_create_size	The minimum size of a new chunk that the server can create when automatically expanding this space using the storage pool. You can define the size as a number of KB or as a percentage of the total space.	The default create size is set to 10 percent of the total size of the space. The size that you specify affects chunks the server creates automatically. It does not affect any manual chunks that you might create for the associated space.
new_extend_size	The minimum size that the server can use when automatically extending a chunk in an unmirrored dbspace or temporary dbspace. The size can be a specified number of KB or a percentage of the total space.	The default extend size is 10 MB. The size that you specify affects chunks the server extends automatically. It does not affect any manual chunk extensions that you might initiate for the associated space.

Usage

If the create or extend size value is 100 or a lower value, Informix interprets the value as a percentage (for example, 10 = 10 percent and 2.84 = 2.84 percent). If the value is 1000 or higher, the server interprets the value as a specific number of KB. Values 100 - 1000 are not valid.

If you set the create size and the extend size to `0`, Informix does not automatically expand the space, even when the space becomes full. Additionally, if you set the extend size to `0`, you also remove the “Extendable” flag from all chunks in that space. This is an easy way to mark all chunks in a space as not extendable, using one operation.

The create and extend size values are minimum sizes. The actual size by which a space is expanded might be larger, depending on the chunk size of the storage pool entry that the server is using or the amount of space that the server needs at that particular time.

For example, suppose you created a storage pool entry to expand storage space when necessary. Then suppose that a dbspace named **logdbs** is out of free pages and requires an extra 500 MB for a new log. If none of the chunks in **logdbs** can be extended, Informix adds a chunk that has the minimum size that is specified by the create size value for the **logdbs** dbspace. If the create size for the **logdbs** dbspace is less than or equal to 500 MB, the server attempts to find a minimum of 500 MB of space. If the create size for **logdbs** is 1 GB, the server ignores the requested size and adds a 1 GB chunk.

If the server is unable to find the minimum amount of space that is required, the server returns an out-of-space error and the log creation fails.

If you set the maximum size of the storage space to a value other than 0, the storage space cannot exceed the maximum size, regardless of the new extend size. When the amount of expansion space that is left before the maximum size is less than the new extend size, the extend size is truncated and the space is extended to the maximum size. The event alarm 86001 is triggered when the space reaches the maximum size. When the amount of expansion space left is less than the minimum chunk size for the storage pool, the space is not expanded and an error is returned.

Examples

The following command sets the minimum create size to 60 MB, the minimum extend size to 10 MB, and the maximum size to 100 MB for a dbspace that is named **dbspace3**:

```
EXECUTE FUNCTION task("modify space sp_sizes", "dbspace3", "60000",
     "10000", "100000");
```

The following command sets the minimum create size to 20 percent and the minimum extend size 1.5 percent for a dbspace that is named **dbspace8**:

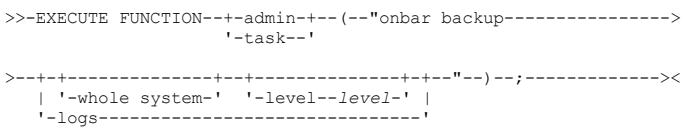
```
EXECUTE FUNCTION task("modify space sp_sizes", "dbspace8", "20", "1.5");
```

Related reference:
modify chunk extendable argument: Mark a chunk as extendable (SQL administration API)
modify chunk extend argument: Extend the size of a chunk (SQL administration API)
modify space expand argument: Expand the size of a space (SQL administration API)

onbar argument: Backup the storage spaces (SQL administration API)

Use the onbar argument with the **admin()** or **task()** function to backup the storage spaces.

Syntax



Element	Purpose	Key considerations
onbar backup	Performs a complete backup of the storage spaces	If you do not specify a level, a level 0 backup is performed.
whole system	Performs a whole-system backup	This is equivalent of issuing the **onbar** command with the -w option from the command line. If you do not specify a level, a level 0 backup is performed.
level *level*	Specifies the level of backup to perform on storage spaces: • 0 for a complete backup. This is the default. • 1 for changes since the last level-0 backup • 2 for changes since the last level-1 backup	If you request an incremental backup and a level backup has not been performed for a particular storage space, this function backs up that storage space at the previous level. For example, if you request a level-1 backup, and the function finds no level-0 backup, a level-0 backup is made instead. This is equivalent of issuing the **onbar** command with the -L *level* option from the command line.
logs	Performs a back of the logical-log files	This is equivalent of issuing the **onbar** command with the -l option from the command line.

Usage

This function is equivalent to invoking specific options of the **onbar** command to create backups of the storage spaces and logical-log files.

Examples

The following example creates a level 0 backup of the storage spaces:

```
EXECUTE FUNCTION task("onbar backup");
```

The following example creates a level 1 backup of the storage spaces:

```
EXECUTE FUNCTION task("onbar backup level 1");
```

The following example creates a level 1 backup of the logical-log files:

```
EXECUTE FUNCTION task("onbar backup logs");
```

The following example creates a whole system level 0 backup of the storage spaces:

```
EXECUTE FUNCTION task("onbar backup whole system");
```

The following example creates a whole system level 2 backup of the storage spaces:

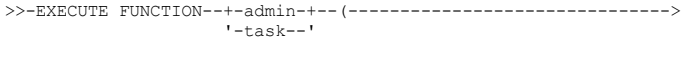
```
EXECUTE FUNCTION task("onbar backup whole system level 2");
```

Related information:
Back up with ON-Bar
onbar -b syntax: Backing up

onmode and a arguments: Add a shared-memory segment (SQL administration API)

Use the onmode and a arguments with the **admin()** or **task()** function to add a shared-memory segment.

Syntax



Element	Description	Key Considerations
memory_size	The size, in kilobytes, of a new virtual shared-memory segment.	The value of *size* must be a positive integer that does not exceed the operating-system limit on the size of shared-memory segments.

Usage

Ordinarily, you do not need to add segments to the virtual portion of shared memory because the database server automatically adds segments as they are needed. However, as segments are added, the database server might reach the operating-system limit for the maximum number of segments before it acquires the memory that it needs. This situation typically occurs when the SHMADD configuration parameter is set so small that the database server exhausts the number of available segments before it acquires the memory that it needs for some operation.

You can use this function to add a segment that is larger than the size specified by the SHMADD configuration parameter. By using this function to add a segment, you can adhere to the operating system limit for segments while meeting the need that the database server has for more memory.

This function is equivalent to the **onmode -a** command.

Example

The following example adds 500 KB of virtual shared-memory:

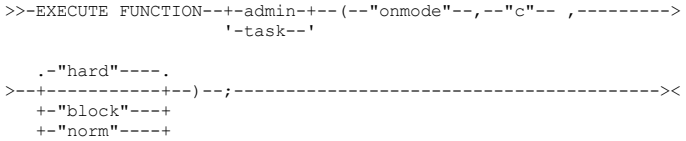
```
EXECUTE FUNCTION task("onmode","a","500");
```

Related reference:
onmode -a: Add a shared-memory segment

onmode and c arguments: Force a checkpoint (SQL administration API)

Use the onmode and c arguments with the **admin()** or **task()** function to force a checkpoint.

Syntax



```
'-"unblock"-'
```

Usage

This function forces a checkpoint that flushes the buffers to disk. You can use the **c** option to force a checkpoint if the most recent checkpoint record in the logical log was preventing the logical-log file from being freed (status U-B-L).

Use the block argument to prevent the database server from processing any transactions. Use this option to perform an external backup on Informix®. While the database server is blocked, users cannot access it, except in read-only mode. No transactions can complete until the database server is unblocked.

Use the hard argument to force a blocking checkpoint. This is the default.

Use the norm argument to force a nonblocking checkpoint.

Use the unblock argument to unblock the database server. When the database server is unblocked, data transactions and normal database server operations can resume. Use this option after you complete an external backup on Informix.

This function is equivalent to the **onmode -c** command.

Example

The following example starts a blocking checkpoint:

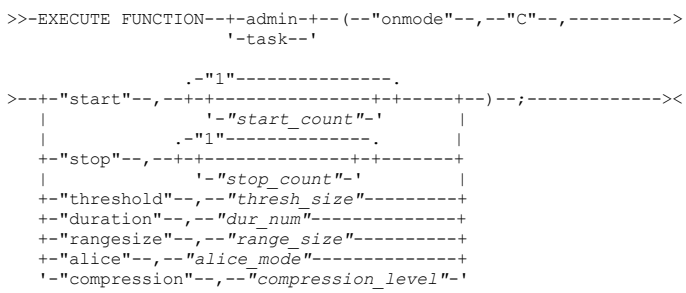
```
EXECUTE FUNCTION task("onmode","c","hard");
```

Related reference:
onmode -c: Force a checkpoint

onmode and C arguments: Control the B-tree scanner (SQL administration API)

Use the onmode and C arguments with the **admin()** or **task()** function to control the B-tree scanner for cleaning indexes of deleted items.

Syntax



Element	Description	Key Considerations
alice_mode	The **alice** mode for the system.	Valid integer values range from `0` (`OFF`) to `12`.
compression_level	For a database server instance, the level at which two partially used index pages are merged. The pages are merged if the data on those pages totals a set level.	Valid values for the level are `low`, `med` (medium), `high`, and `default`. The system default value is `med`.
dur_num	The number of seconds that the hot list is valid.	After this number of seconds expires, the hot list will be rebuilt by the next available B-tree scanner thread, even if unprocessed items are on the list. Scanners that are processing requests are not interrupted.
range_size	The size of an index before index range cleaning is enabled.	A size of `-1` can be used to disable range scanning.
start_count	The number of B-tree scanner threads to start.	If *start_count* is not specified, 1 more thread is started. A maximum of 32 threads can be started at one time. But, there is no limit on the number of scanner threads run simultaneously.
stop_count	The number of B-tree scanner threads to stop.	If *stop_count* is not specified, a single thread is stopped. Stopping all index scanners prevents all index cleaning. If you specify a larger *stop_count* value than the number of threads than are running, no error is issued, but all scanner threads are stopped.
thresh_size	The minimum number of deleted items an index must encounter before an index is placed on the hot list.	After all indexes above the threshold have been cleaned and there is no other work for the B-tree scanner to do, the indexes below the threshold are added to the hot list.

Usage

The B-tree scanner has statistical information that tracks index efficiency and how much extra work the index places on the server. Based on the amount of extra work the index has accomplished because of committed deleted index items, the B-tree scanner develops an ordered list of indexes that have caused the server to do extra work, called the hot list. The index causing the highest amount of extra work is cleaned first and the rest of the indexes are cleaned in descending order. The DBA can allocate cleaning threads dynamically to configure workloads.

This function is equivalent to the **onmode -C** command.

Example

The following commands start 60 B-tree scanner threads:

```
EXECUTE FUNCTION admin("onmode","C","start","30");
EXECUTE FUNCTION admin("onmode","C","start","30");
```

The following command stops all of these threads:

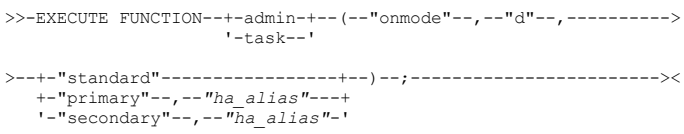
```
EXECUTE FUNCTION admin("onmode","C","stop","30000");
```

No error is issued when the *stop_count* value is greater than the number of running threads.
Related reference:
onmode -C: Control the B-tree scanner
BTSCANNER Configuration Parameter

onmode and d arguments: Set data-replication types (SQL administration API)

Use the onmode and d arguments with the **admin()** or **task()** function to change the mode of a server participating in high-availability data replication (HDR).

Syntax



Element	Description	Key Considerations
ha_alias	The high-availability alias of the primary or secondary database server.	*ha_alias* must correspond to the HA_ALIAS configuration parameter in the ONCONFIG file of the intended secondary database server.

Usage

Use this function to set the High-Availability Data Replication type as standard, primary, or secondary. You can use the standard argument when the database server is in quiescent, online, or read-only mode.

The *ha_alias* argument of the other database server in the data-replication pair and the type of a database server (standard, primary, or secondary) is preserved after reinitialization of shared memory.

The **standard** argument drops the connection between database servers in a data replication pair (if one exists) and sets the database server type of the current database server to standard. This option does not change the mode or type of the other database server in the pair.

The **primary** and *ha_alias* arguments set the database server type to primary and attempt to connect with the database server that *ha_alias* specifies. If the connection is successful, data replication is turned on. The primary database server goes into online mode, and the secondary database server goes into read-only mode. If the connection is not successful, the database server comes to online mode, but data replication is not turned on.

The **secondary** and *ha_alias* arguments set the database server type to secondary and attempt to connect with the database server that *ha_alias* specifies. If the connection is successful, data replication is turned on. The primary database server goes online, and the secondary database server goes into read-only mode. If the connection is not successful, the database server comes to read-only mode, but data replication is not turned on.

This function is equivalent to the **onmode -d** command.

Example

The following example sets a server named **ids_stores** as an HDR primary server:

```
EXECUTE FUNCTION task("onmode","d","primary","ids_stores");
```

Related reference:
onmode -d: Set data-replication types

onmode and D arguments: Set PDQ priority (SQL administration API)

Use the onmode and D arguments with the **admin()** or **task()** function to temporarily reset the PDQ resources that the database server can allocate to any one decision-support query.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"onmode"-- , -"D"--,--"max_priority"--)--;------------------><
```

Element	Description	Key Considerations
max_priority	The percentage of the user-requested PDQ resources actually allocated to the query.	The value must be an unsigned integer from 0 to 100.

Usage

Use this function to override the limit set by the MAX_PDQPRIORITY configuration parameter while the database server is online. The new values affect only the current instance of the database server; the values are not recorded in the **onconfig** file. If you shut down and restart the database server, the values of the parameter reverts to the values in the **onconfig** file.

This function is equivalent to the **onmode -D** command.

Example

The following example sets the percentage of PDQ resources that can be allocated to a query to 50 percent:

```
EXECUTE FUNCTION task("onmode","D","50");
```

Related reference:
onmode -D, -M, -Q, -S: Change decision-support parameters

onmode and e arguments: Change usage of the SQL statement cache (SQL administration API)

Use the onmode and e arguments with the **admin()** or **task()** function to temporarily change the mode of the SQL statement cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onmode"--,--"e"--,---------->
                     '-task--'

>--+-"enable"-+--)--;----------------------------------------><
   +-"flush"--+
   +-"off"----+
   '-"on"-----'
```

Usage

Use the enable argument to enable the SQL statement cache if it is disabled. Individual user sessions can use the statement cache only after they perform either of the following actions:

- Set the environment variable **STMT_CACHE** to `1`.
- Execute the SQL statement SET STATEMENT CACHE ON.

Use the flush argument to flush the statements that are not in use from the SQL statement cache, which remains enabled. After the cache is flushed, the **onstat -g ssc ref_cnt** field shows 0.

Use the off argument to turn off the SQL statement cache, so that no statements are cached.

Use the on argument to cache all statements except those a user turns off by one of the following actions:

- Use this command to specify the OFF mode.
- Set the environment variable **STMT_CACHE** to `0`.
- Execute the SQL statement SET STATEMENT CACHE OFF statement.

This function cannot modify the STMT_CACHE configuration parameter setting in the ONCONFIG file, but the last argument overrides that setting (or the default value, if STMT_CACHE is not set). Any changes to the statement cache behavior that you make with this command are in effect for the current database server session only. When you restart the database server, it uses the setting of the STMT_CACHE parameter in the ONCONFIG file. If the STMT_CACHE configuration parameter is not defined in the ONCONFIG file, the server does not use a statement cache.

This function is equivalent to the **onmode -e** command.

Example

The following example enables the SQL statement cache:

```
EXECUTE FUNCTION task("onmode","e","enable");
```

Related reference:
onmode -e: Change usage of the SQL statement cache

onmode and F arguments: Free unused memory segments (SQL administration API)

Use the onmode and F arguments with the **admin()** or **task()** function to free unused memory segments.

Syntax

Usage

When you execute this function, the memory manager examines each memory pool for unused memory. The memory manager immediately frees unused blocks of memory that it locates. After the memory manager checks each memory pool, it begins checking memory segments and frees any that the database server no longer needs.

Running this command causes a significant degradation of performance for any users that are active when you execute the utility. Although the execution time is brief (1 to 2 seconds), degradation for a single-user database server can reach 100 percent. Systems with multiple CPU virtual processors experience proportionately less degradation.

To confirm that the unused memory was freed, check the message log. If the memory manager frees one or more segments, it displays a message that indicates how many segments and bytes of memory were freed.

Tip: Run this command from an operating-system scheduling facility regularly and after the database server performs any function that creates more memory segments, including large index builds, sorts, or backups.
This function is equivalent to the **onmode -F** command.

Example

The following example frees unused memory blocks:

```
EXECUTE FUNCTION task("onmode","F");
```

Related reference:
onmode -F: Free unused memory segments

onmode and h arguments: Update sqlhosts caches (SQL administration API)

Use the onmode and h arguments with the **admin()** or **task()** function to Update sqlhosts caches.

Syntax

Usage (UNIX only)

You can use this function only when the database server is in online mode.

This function is equivalent to the **onmode -h** command.

Example

The following example triggers an unconditional reload of the sqlhosts caches:

```
EXECUTE FUNCTION task("onmode", "h", "force");
```

onmode and j arguments: Switch the database server to administration mode (SQL administration API)

Use the onmode and j arguments with the **admin()** or **task()** function to change the database server to administration mode.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onmode"--,--"j"--)--;------><
                     '-task--'
```

Usage

When the server is changed to administration mode, all sessions lose their connection to the database server except for sessions of the following users:

- User **informix**
- Users in the **DBSA** group
- Users who are identified in ADMIN_MODE_USERS settings

This function is equivalent to the **onmode -j** command.

Example

The following example changes the server to administration mode:

```
EXECUTE FUNCTION task("onmode","j");
```

Related reference:
onmode -k, -m, -s, -u, -j: Change database server mode

onmode and l arguments: Switch to the next logical log (SQL administration API)

Use the onmode and l arguments with the **admin()** or **task()** function to switch the current logical-log file to the next logical-log file.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onmode"--,--"l"--)--;------><
                     '-task--'
```

Usage

This function is equivalent to the **onmode -l** command.

For information on switching to the next logical-log file, see the section on managing logical-log files in the *IBM® Informix® Administrator's Guide*.

Example

The following example moves the logical log out of the **root** chunk

```
SELECT task("onmode", "l") FROM sysmaster:syslogfil
   WHERE chunk = 1 AND sysmaster:bitval(flags,"0x02")>0;
```

Related reference:
onmode -l: Switch the logical-log file

onmode and m arguments: Switch to multi-user mode (SQL administration API)

Use the onmode and m arguments with the **admin()** or **task()** function to change the database server to multi-user mode.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onmode"--,--"m"--)--;------><
                    '-task--'
```

Usage

Use this function to bring the database server online from quiescent mode or from administration mode.

This function is equivalent to the **onmode -m** command.

Example

The following example changes the server to multi-user mode:

```
EXECUTE FUNCTION task("onmode","m");
```

Related reference:
onmode -k, -m, -s, -u, -j: Change database server mode

onmode and M arguments: Temporarily change decision-support memory (SQL administration API)

Use the onmode and M arguments with the **admin()** or **task()** function to temporarily change the size of memory available for parallel queries.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                    '-task--'

>--"onmode"--,--"M"--,--"memory_size"--)--;--------------------><
```

Element	Description	Key Considerations
memory_size	The new size limit (in kilobytes) of the maximum amount of memory available for parallel queries.	The maximum value for 32-bit platform is 2 gigabytes. The maximum value for 64-bit platform is 4 gigabytes.

Usage

Use this function to override the limit set by the DS_TOTAL_MEMORY configuration parameter while the database server is online. The new values affect only the current instance of the database server; the values are not recorded in the ONCONFIG file. If you shut down and restart the database server, the values of the parameter revert to the values in the ONCONFIG file.

This function is equivalent to the **onmode -M** command.

Example

The following example sets the size limit for parallel queries to 50 MB:

```
EXECUTE FUNCTION task("onmode","M","50000");
```

Related reference:
onmode -D, -M, -Q, -S: Change decision-support parameters

onmode and n arguments: Unlock resident memory (SQL administration API)

Use the onmode and n arguments with the **admin()** or **task()** function to end forced residency of the resident portion of shared memory.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onmode"--,--"n"--)--;------><
                    '-task--'
```

Usage

The RESIDENT configuration parameter must be set to `1` in the ONCONFIG file before you can run this function.

This function does not affect the value of the RESIDENT configuration parameter, the forced-residency parameter in the ONCONFIG file.

This function is equivalent to the **onmode -n** command.

Example

The following example unlocks resident memory:

```
EXECUTE FUNCTION task("onmode","n");
```

Related reference:
onmode -n, -r: Change shared-memory residency

onmode and O arguments: Mark a disabled dbspace as down (SQL administration API)

Use the onmode and O arguments with the **admin()** or **task()** function to mark a disabled dbspace as down so that the checkpoint that is being blocked by the disabled dbspace can continue and any blocked threads are released.

Syntax

Usage

This function overrides the WAIT mode of the ONDBSPACEDOWN configuration parameter. Use this command only in the following circumstances:

- ONDBSPACEDOWN is set to WAIT.
- A disabling I/O error occurs that causes the database server to block all updating threads.
- You cannot or do not want to correct the problem that caused the disabling I/O error.
- You want the database server to mark the disabled dbspace as down and continue processing.

This function is equivalent to the **onmode -O** command.

Example

The following example marks disabled dbspaces as down:

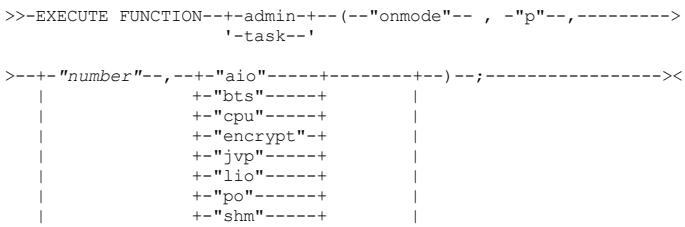
```
EXECUTE FUNCTION task("onmode","O");
```

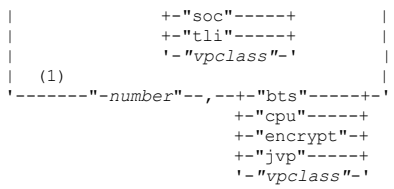
Related reference:
onmode -O: Override ONDBSPACEDOWN WAIT mode

onmode and p arguments: Add or remove virtual processors (SQL administration API)

Use the onmode and p arguments with the **admin()** or **task()** function to dynamically add or remove virtual processors for the current database server session. This function does not update the onconfig file.

Syntax





Notes:

1. UNIX only

Element	Description	Key Considerations
number	The number of virtual processors to add or to remove.	A positive number adds virtual processors. The maximum number of virtual processors you can add depends on the operating system. UNIX: A negative number removes virtual processors. The number of virtual processors to drop cannot exceed the actual number of processors of the specified type.
vpclass	The name of a user-defined virtual processor class.	Windows: The *number* argument must be set to `1` because you can only create one instance of a user-defined virtual processor.

Usage

You can use this function only when the database server is in online mode.

The number of CPU VPs should not exceed the number of physical processors on your system, but no error is issued if they do. The database server uses the number of CPU VPs to allocate resources for parallel database queries (PDQ). If you drop CPU VPs, your queries might run significantly slower. After you change the number of CPU VPs, the **Reinit** field in the output from the **onstat -g mgm** command shows how many queries are waiting for other queries to complete.

See the *IBM® Informix® Performance Guide* for more information about performance implications of the CPU VP class.

For a description of each virtual processor class, see the *IBM Informix Administrator's Guide*.

This function is equivalent to the **onmode -p** command.

Example

The following example adds one CPU virtual processor:

```
EXECUTE FUNCTION task("onmode","p","1","cpu");
```

The following example removes one Java™ virtual processor:

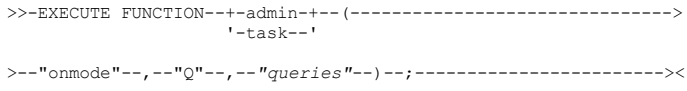
```
EXECUTE FUNCTION task("onmode","p","-1","jvp");
```

Related reference:
onmode -p: Add or drop virtual processors

onmode and Q arguments: Set maximum number for decision-support queries (SQL administration API)

Use the onmode and Q arguments with the **admin()** or **task()** function to change the maximum number of concurrently executing decision-support queries.

Syntax



Element	Description	Key Considerations
queries	The maximum number of concurrently executing parallel queries.	The number must be an unsigned integer from 1 to 8,388,608.

Usage

Use this function to override the limit set by the DS_MAX_QUERIES configuration parameter while the database server is online. The new values affect only the current instance of the database server; the values are not recorded in the ONCONFIG file. If you shut down and restart the database server, the values of the parameter revert to the values in the ONCONFIG file.

For information on parameters used for controlling PDQ, see the *IBM® Informix® Performance Guide*.

This function is equivalent to the **onmode -Q** command.

Example

The following example sets the maximum number of concurrently executing parallel queries to 8:

```
EXECUTE FUNCTION task("onmode","Q","8");
```

Related reference:
onmode -D, -M, -Q, -S: Change decision-support parameters

onmode and r arguments: Force residency of shared memory (SQL administration API)

Use the onmode and r arguments with the **admin()** or **task()** function to start forced residency of the resident portion of shared memory.

Syntax

Usage

The RESIDENT configuration parameter must be set to `1` in the ONCONFIG file before you can run this function.

This function does not affect the value of the RESIDENT configuration parameter, the forced-memory parameter in the ONCONFIG file.

This function is equivalent to the **onmode -r** command.

Example

The following example starts forced residency of shared memory:

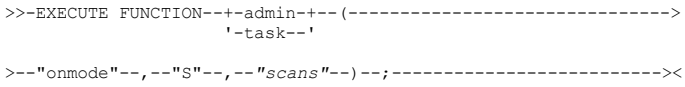
```
EXECUTE FUNCTION task("onmode","r");
```

Related reference:
onmode -n, -r: Change shared-memory residency

onmode and S arguments: Set maximum number of decision-support scans (SQL administration API)

Use the onmode and S arguments with the **admin()** or **task()** function to change the maximum number of concurrently executing decision-support scans for the current session.

Syntax



Element	Description	Key Considerations
scans	The maximum number of concurrently executing parallel scans.	The number must be an unsigned integer from 10 to 1 048 576.

Usage

Use this function to override the limit set by the DS_MAX_SCANS configuration parameter while the database server is online. The new value affects only the current instance of the database server; the values are not recorded in the ONCONFIG file. If you shut down and restart the database server, the value of the parameter reverts to the value in the ONCONFIG file.

For information on parameters used for controlling PDQ, see the *IBM® Informix® Performance Guide*.

This function is equivalent to the **onmode -S** command.

Example

The following example sets the maximum number of concurrently executing parallel scans to 2000:

```
EXECUTE FUNCTION task("onmode","S","2000");
```

Related reference:
onmode -D, -M, -Q, -S: Change decision-support parameters

onmode and W arguments: Reset statement cache attributes (SQL administration API)

Use the onmode and W arguments with the **admin()** or **task()** function to change whether and when a statement can be inserted into the SQL cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onmode"--,--"W"--,---------->
                     '-task--'

>--+-"STMT_CACHE_HITS"--,--"hits"-----+--)--;------------------><
   '-"STMT_CACHE_NOLIMIT"--,--"value"-'
```

Element	Description	Key Considerations
hits	The number of hits (references) to a statement before it is fully inserted in the SQL statement cache.	Possible values are: • 0 = Insert all qualified statements and their memory structures in the cache. • 1 or more = Exclude ad hoc queries from entering the cache.
value	Whether statements are inserted in the SQL statement cache.	Possible values are: • 0 = The database server does not insert statements into the cache. • 1 = The database server always inserts statements in the cache.

Usage

Use this function to reset the value of the STMT_CACHE_HITS or STMT_CACHE_NOLIMIT configuration parameter while the database server is online. The new value affects only the current instance of the database server; the value is not recorded in the ONCONFIG file. If you shut down and restart the database server, the value of the parameter reverts to the value in the ONCONFIG file.

If you set the value of STMT_CACHE_HITS equal to 0, the database server inserts all qualified statements and their memory structures in the cache. If the value is greater than 0 and the number of times the SQL statement has been executed is less than the value of STMT_CACHE_HITS, the database server inserts *key-only* entries in the cache. The database server inserts qualified statements in the cache after the specified number of hits has occurred for the statement. The new value of STMT_CACHE_HITS displays in the **#hits** field of the **onstat -g ssc** output.

If none of the queries are shared, set STMT_CACHE_NOLIMIT to 0 to prevent the database server from allocating a large amount of memory for the statement cache.

This function is equivalent to the **onmode -W** command.

Example

The following example prevents ad hoc queries from entering the SQL statement cache:

```
EXECUTE FUNCTION task("onmode","W","STMT_CACHE_HITS","1");
```

Related reference:
onmode -W: Change settings for the SQL statement cache

onmode and wf arguments: Permanently update a configuration parameter (SQL administration API)

Use the onmode and wf arguments with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in the **onconfig** file.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
```

```
                    '-task--'

>--"onmode"--,--"wf"--,--"configuration_parameter_name=new_value"--)--;-><
```

Element	Description	Key Considerations
configuration_parameter_name	The name of a configuration parameter.	The configuration parameter must be one that you can update dynamically. The list of configuration parameters that you can update dynamically is the same as for the **onmode -wf** command.
new_value	The new value or values for the configuration parameter.	The value must be valid for the configuration parameter. The format of the new value must conform exactly to the syntax for that configuration parameter.

Usage

Use this function to permanently update the value of a configuration parameter. The new value takes effect immediately and persists in the ONCONFIG file after the server restarts.

This function is equivalent to the **onmode -wf** command.

Example

The following example sets the value of the DYNAMIC_LOGS configuration parameter to 2 in the **onconfig** file:

```
EXECUTE FUNCTION task("onmode","wf","DYNAMIC_LOGS=2");
```

Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters

onmode and wm arguments: Temporarily update a configuration parameter (SQL administration API)

Use the onmode and wm arguments with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in memory.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                    '-task--'

>--"onmode"--,--"wm"--,--"configuration_parameter_name=new_value"--)--;-><
```

Element	Description	Key Considerations
configuration_parameter_name	The name of a configuration parameter.	The configuration parameter that you specify must be one that you can update dynamically. The list of configuration parameters that you can update dynamically is the same as for the **onmode -wf** command.
new_value	The new value or values for the configuration parameter.	The value must be valid for the configuration parameter. The format of the new value must conform exactly to the syntax for that configuration parameter.

Usage

Use this function to temporarily update the value of a configuration parameter that can be dynamically updated. The new value takes effect immediately. The new value is not written to the ONCONFIG file and is lost when the database server is restarted.

This function is equivalent to the **onmode -wm** command.

Example

The following example sets the value of the DYNAMIC_LOGS configuration parameter to 2 for the current session:

```
EXECUTE FUNCTION task("onmode","wm","DYNAMIC_LOGS=2");
```

Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters

onmode, wm, and AUTO_LRU_TUNING arguments: Change LRU tuning status (SQL administration API)

Use the onmode, wm, and AUTO_LRU_TUNING arguments with the **admin()** or **task()** function to change the LRU tuning status without updating the onconfig file. .

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onmode"--,--"wm"--,--------->
                     '-task--'

>--+-"AUTO_LRU_TUNING=0-+--"--)--;----------------------------><
   '-"AUTO_LRU_TUNING=1-'
```

Usage

Use the AUTO_LRU_TUNING =1 argument to enable automatic LRU tuning.

Use the AUTO_LRU_TUNING=0 argument to disable automatic LRU tuning .

This function is equivalent to the **onmode -wm AUTO_LRU_TUNING** command.

Example

The following example enables automatic LRU tuning:

```
EXECUTE FUNCTION task("onmode","wm","AUTO_LRU_TUNING=1");
```

Related reference:
onmode -wm: Change LRU tuning status

onmode and Y arguments: Change query plan measurements for a session (SQL administration API)

Use the onmode and Y arguments with the **admin()** or **task()** function to change the output of query plan measurements for an individual session.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"onmode"--,--"Y"--"session_id"--,---------------------------->

>--+-0-----------------------+--)--;--------------------------><
   '-+-2-+--+--------------+-'
     '-1-'  '-,--file_name-'
```

Element	Description	Key Considerations
file_name	The explain output file name.	If the file's absolute path is not included, the example output file is created in the default example output file location. If the file already exists, explain output is appended to it. If a file already exists from the SET EXPLAIN statement, that file is not used until dynamic explain is turned off.
session_id	Identifies the specific session.	None.
-Y	Dynamically change the value of the SET EXPLAIN statement.	None.

Usage

You can use this function to emulate the SET EXPLAIN statement.

The last argument determines if record query measurements, including the plan of the query optimizer, an estimate of the number of rows returned, and the relative cost of the query.

Use the 2 argument to enable the database server to send the query plan to the explain output file.

Use the 1 argument to enable the database server to send the query plan and statistics, to the explain output file. This setting is equivalent to the SET EXPLAIN ON statement for a specific session.

Use the 0 argument to disable the output of query measurements to the explain output file for the current session. This setting is equivalent to the SET EXPLAIN OFF statement.

This function is equivalent to the **onmode -Y** command.

Example

The following example disables the output of query measurements for user session with an ID of 32:

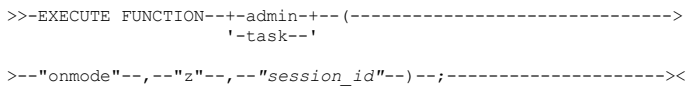
```
EXECUTE FUNCTION task("onmode","Y","32","0");
```

Related reference:
onmode -Y: Dynamically change SET EXPLAIN
Related information:
SET EXPLAIN statement
Using the FILE TO option
Default name and location of the explain output file on UNIX
Default name and location of the output file on Windows
Report that shows the query plan chosen by the optimizer
The explain output file
Query statistics section provides performance debugging information

onmode and z arguments: Terminate a user session (SQL administration API)

Use the onmode and z arguments with the **admin()** or **task()** function to terminate the specified user session.

Syntax



Element	Description	Key Considerations
session_id	The session ID.	The value must be an unsigned integer greater than 0, and must be the session identification number of a currently running session.

Usage

This function is equivalent to the **onmode -z** command.

Example

The following example terminates the user session with an ID of 14:

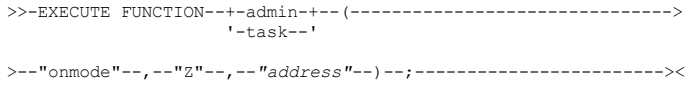
```
EXECUTE FUNCTION task("onmode","z","14");
```

Related reference:
onmode -z: Kill a database server session

onmode and Z arguments: Terminate a distributed transaction (SQL administration API)

Use the onmode and Z arguments with the **admin()** or **task()** function to terminate the specified distributed transaction. Use this function only if communication between the participating database servers has been lost. If applications are performing distributed transactions, terminating one of the distributed transactions can leave your client/server database system in an inconsistent state.

Syntax



Element	Description	Key Considerations

Element	Description	Key Considerations
address	The shared-memory address associated with a distributed transaction.	This must be the address of an ongoing distributed transaction that has exceeded the amount of time that the TXTIMEOUT configuration parameter specifies. The *address* must conform to the operating-system-specific rules for addressing shared-memory. This address is available from **onstat -x** output.

Usage

This function succeeds only if the distributed transaction has exceeded the amount of time that the TXTIMEOUT configuration parameter specifies.

This function is equivalent to the **onmode -Z** command.

Example

The following example terminates a distributed transaction with an address of `0xa509018`:

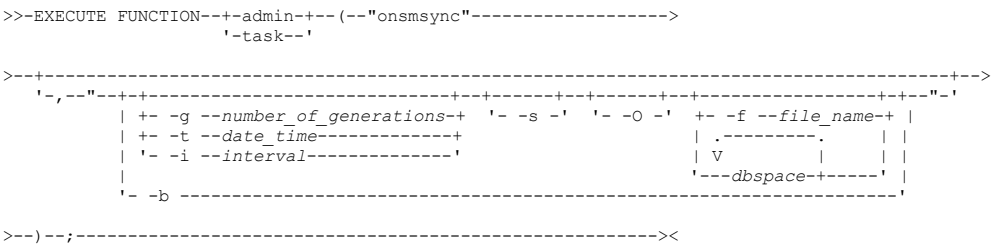
```
EXECUTE FUNCTION task("onmode","Z","0xa509018");
```

Related reference:
onmode -Z: Kill a distributed transaction

onsmsync argument: Synchronize with the storage manager catalog (SQL administration API)

Use the onsmsync argument with the **admin()** or **task()** function to synchronize the **sysutils** database and emergency boot file with the storage manager catalog.

Syntax



Element	Purpose	Key considerations
no options	Synchronizes the **sysutils** database and emergency boot file with the storage-manager catalog	None.
-b	Regenerates both the emergency boot file (ixbar.*servernum*) and the **sysutils** database from each other.	If the ixbar file is empty or does not exist, **onsmsync -b** recreates the ixbar file and populates it from the **syutils** tables. If the ixbar is not empty and contains object data, **onsmsync -b** updates the **sysutils** database and the ixbar file so that they are in sync. If the ixbar file has entries and the **sysutils** database has been rebuilt, but is empty because it does not contain data, the **onsmsync -b** option recreates the **sysutils** data from the ixbar file. The -b element is not used with the other **onsmsync** options. Additionally, it does not synchronize with the storage manager.
dbspace	Specifies the storage space or storage spaces to expire	If you enter more than one storage space, use a space to separate the names.
-f *file_name*	Specifies the path name of a file that contains a list of storage spaces to expire	Use this option to avoid entering a long list of storage spaces. The file name can be any valid UNIX or Windows file name.
-g *number_of_generations*	Retains a certain number of versions of each level-0 backup	The latest generation of backups are retained and all earlier ones are expired.
-i *interval*	Expires all backups older than some period of time	Retains backups younger than this interval. Backups older than interval are not expired if they are needed to restore from other backups after that interval. Use the ANSI or GLS format for the *interval*: YYYY-MM or DD HH:MM:SS
-s	Skips backups that the storage manager has expired	Use this option to skip synchronizing objects that are already expired from the storage manager. The object expiration will be based on other arguments if the -s option is provided.

Element	Purpose	Key considerations
-O	Enforces expiration policy strictly	If used with the -t, -g, or -i option, expires all levels of a backup, even if some of them are needed to restore from a backup that occurred after the expiration date. The -O option does not affect logical-log expiration. See Expire all backups.
-t *date_time*	Expires all backups before a particular date and time	Retains backups younger than this *datetime*. Backups older than *datetime* are not expired if they are needed to restore from other backups after that *datetime*. Use the ANSI or GLS_DATETIME format for *datetime*.

Usage

This function invokes the **onsmsync** utility to synchronize the **sysutils** database and emergency boot file with the storage manager catalog.

Example

The following example invokes the **onsmsync** utility and specifies that number of backups retained is 1 and all earlier backup versions are expired:

```
EXECUTE FUNCTION task("onsmsync", "-g 1");
```

Related information:
The onsmsync utility

onstat argument: Monitor the database server (SQL administration API)

Use the onstat argument with the **admin()** or **task()** function to monitor the database server.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"onstat"--,--"--option_name--"--)-- ;-><
                     '-task--'
```

Element	Description	Key Considerations
option_name	The **onstat** command option.	The option must include a hyphen and conform to **onstat** option syntax. For **onstat** options, see The onstat utility.

Usage

Use these commands to display the same information about the database server as running the **onstat** utility commands.

Example

The following example runs the **onstat -g ses** command:

```
EXECUTE FUNCTION task("onstat","-g ses");
```

Related reference:
The onstat utility

ontape archive argument: Backup the data on your database (SQL administration API)

Use the ontape archive argument with the **admin()** or **task()** function to create a backup of your database data.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"ontape archive-------------->
                     '-task--'

   .-file------.
>--+-----------+--+-------------+--"--,--"location"-------------->
   +-directory-+  |       .-0-. |
   '-tape------'  '-level-+-1-+-'
                          '-2-'
```

```
>--+---------------+--)--;-------------------------------------><
   '-,"block_size"-'
```

Element	Description	Key Considerations
location	The path to the file or directory or tape device.	
block_size	The block size, in KB, of the device to which ontape writes during a storage-space backup.	The default block size is 512 KB.

Usage

This function invokes the ontape utility to create a backup.

There are three devices that you can choose from for the location of the backup:

file
: An existing file. This is the default value.

directory or dir
: An existing directory path specified by *location*.

tape
: An existing tape device.

Examples

This function creates a level 0 archive in the directory path /local/informix/backup/:

```
EXECUTE FUNCTION task("ontape archive","/local/informix/backup/");
```

This function creates a level 0 archive in the directory path /local/informix/backup/ with a block size of 256 KB:

```
EXECUTE FUNCTION task("ontape archive directory level 0",
"/local/informix/backup/","256");
```

Related information:
Back up with ontape

print error argument: Print an error message (SQL administration API)

Use the print error argument with the **admin()** or **task()** function to print the message associated with the specified error number.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"print error"--,--"error_number"--)--;----------------------><
```

Element	Description	Key Considerations
error_number	The error number, without a minus sign.	The *error_number* must be an existing error number.

Usage

This function is equivalent to the **finderr** utility.

Example

The following example prints the message text for the error number -105:

```
EXECUTE FUNCTION task("print error","105");
(expression)  ISAM error:  bad isam file format.
```

print file info argument: Display directory or file information (SQL administration API)

Use the print file info argument with the **admin()** or **task()** function to display information about a directory or a file

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                    '-task--'

>--(--"print file info"--,--"--file_path--"--)--;-------------><
```

Element	Purpose	Key considerations
file_path	The path to the directory or file	

Example: File information

The following example shows the argument you would use to print information about the `x` file that is in the /tmp directory:

```
execute function task("print file info","/tmp/x");
```

The following information is returned:

```
(expression)  File name           = /tmp/x
              Is File             = 1
              Is Directory        = 0
              Is Raw Device       = 0
              Is Block Device     = 0
              Is Pipe             = 0
              File Size           = 554
              Last Access Time    = 11/29/2010 21:55:02
              Last Modified Time  = 11/29/2010 21:51:45
              Status Change Time  = 11/29/2010 21:51:45
              User Id             = 200
              Group id            = 102
              File Flags          = 33206
```

Example: Directory information

The following example shows the argument that you would use to print information about the `/tmp` directory:

```
execute function task("print file info","/tmp");
```

The following information is returned:

```
(expression)  File name           = /tmp
              Is File             = 0
              Is Directory        = 1
              Is Raw Device       = 0
              Is Block Device     = 0
              Is Pipe             = 0
              File Size           = 32768
              Last Access Time    = 12/06/2010 11:53:00
              Last Modified Time  = 12/06/2010 12:05:53
              Status Change Time  = 12/06/2010 12:05:53
              User Id             = 0
              Group id            = 0
              File Flags          = 17407
```

print partition argument: Print partition information (SQL administration API)

Use the print partition argument with the **admin()** or **task()** function to print the headers of a specified partition.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+---------------------------------->
                    '-task--'

>--(--+-"print partition"------+--,--"partition_number"--)--;--><
      '-"print partition full"-'
```

Element	Description	Key Considerations
partition_number	The partition number.	Find the partition numbers in the **partnum** column of the **systables** system catalog table.

Usage

Use this function to print a tblspace report for the specified partition.

Run this function with the full argument to include index-specific information and page-allocation information by page type for dbspaces.

This function with the print partition argument is equivalent to the **oncheck -pt** command.

This function with the print partition full argument is equivalent to the **oncheck -pT** command.

Example

The following example prints the headers for a partition with a number of `1048611`:

```
EXECUTE FUNCTION task("print partition","1048611");
```

Related reference:
oncheck -pt and -pT: Display tblspaces for a Table or Fragment

rename space argument: Rename a storage space (SQL administration API)

Use the rename space argument with the **admin()** or **task()** function to rename a dbspace, blobspace, sbspace, or extspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"rename space"--,--"space_name"--,--"new_name"--)--;-------><
```

Element	Description	Key Considerations
new_name	The new name of the space.	
space_name	The name of the dbspace, blobspace, sbspace, or extspace that you want to rename.	

Usage

This function is equivalent to the **onspaces -ren** command.

Example

The following example renames a dbspace named **dbsp1** to **dbsp2**:

```
EXECUTE FUNCTION task("rename space","dbsp1","dbsp2");
```

Related reference:
onspaces -ren: Rename a dbspace, blobspace, sbspace, or extspace

reset config argument: Revert configuration parameter value (SQL administration API)

Use the reset config argument with the **admin()** or **task()** function to revert the value of a dynamically updatable configuration parameter to its value in the onconfig file. Dynamically updatable configuration parameters are those parameters that you can change for a session with an **onmode** or SQL administration API command.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"--reset config--"----------->
                     '-task--'

>--,--"configuration_parameter_name"--)--;--------------------><
```

Table 1. reset config command elements

Element	Description	Key Considerations
configuration_parameter_name	The name of the configuration parameter with the value that you want to revert.	

Usage

The reset config argument reverts the value of the configuration parameter to the last saved value in the onconfig file, even if the value was changed after the database server started.

Example

The following command reverts the value of the DYNAMIC_LOGS configuration parameter to the value in the onconfig file.

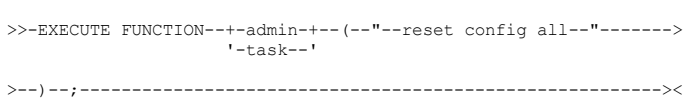
```
EXECUTE FUNCTION task("reset config","DYNAMIC_LOGS");
```

Related tasks:
Modifying the onconfig file
Related reference:
reset config all argument: Revert all dynamically updatable configuration parameter values (SQL administration API)

reset config all argument: Revert all dynamically updatable configuration parameter values (SQL administration API)

Use the reset config all argument with the **admin()** or **task()** function to revert the values of all dynamically updatable configuration parameter to their values in the onconfig file. Dynamically updatable configuration parameters are those parameters that you can change for a session with an **onmode** or SQL administration API command.

Syntax



Usage

The reset config all argument reverts the values of all dynamically updatable configuration parameters to the last saved values in the onconfig file, even if the values were changed after the database server started.

Example

The following command reverts the value of all dynamically tunable configuration parameters.

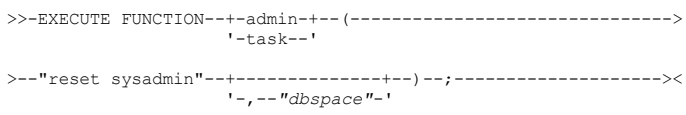
```
EXECUTE FUNCTION task("reset config all");
```

Related tasks:
Modifying the onconfig file
Related reference:
reset config argument: Revert configuration parameter value (SQL administration API)

reset sysadmin argument: Move the sysadmin database (SQL administration API)

Use the reset sysadmin argument with the **admin()** or **task()** function to move the **sysadmin** database to the specified dbspace. Moving the **sysadmin** database resets the database back to the original state when it was first created; all data, **command history**, and results tables are lost. Only built-in tasks, sensors, and thresholds remain in the **sysadmin** tables.

Syntax



Element	Description	Key Considerations
dbspace	The name of the dbspace.	

Usage

This function has no equivalent utility command.

If you specify no *dbspace* as the last argument, this command drops the **sysadmin** database, and then re-creates it in the rootdbs. All **ph_*** table and **command_history** rows are deleted, and all results tables are dropped.

Examples

The following example drops the existing **sysadmin** database and creates a new **sysadmin** database in a dbspace named **dbsp1**:

```
EXECUTE FUNCTION task("reset sysadmin","dbs1");
```

The next example drops the **sysadmin** database, and then re-creates it in the rootdbs.

```
EXECUTE FUNCTION admin("reset sysadmin");
```

Except for the built-in tasks, sensors, and thresholds, all data rows are deleted from the **ph_** tables and all results tables are dropped from **sysadmin** by this function call. The **command_history** table has no rows after the function completes execution.

Related concepts:
The sysadmin Database

restart listen argument: Stop and start a listen thread dynamically (SQL administration API)

Use the restart listen argument with the **admin()** or **task()** function to stop and then start an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"restart listen"--,--"server_name"--)--;--------------------><
```

Element	Description	Key Considerations
server_name	The name of the database server for which you want to stop and restart a listen thread.	

Usage

The definition of the listen thread must exist in the **sqlhosts** file.

If necessary, before you restart a listen thread, revise the **sqlhosts** entry. For example, if a running listen thread is bound to port 7777, you can change the port in the **sqlhosts** file, and then restart the thread.

This function is equivalent to the **onmode -P restart** *server_name* command.

This function does not update the **sqlhosts** file.

Example

The following command stops and then starts a listen thread for a server named **ids_serv1**:

```
EXECUTE FUNCTION task("restart listen","ids_serv1");
```

Related reference:
onmode -P: Start, stop, or restart a listen thread dynamically
start listen argument: Start a listen thread dynamically (SQL administration API)
stop listen argument: Stop a listen thread dynamically (SQL administration API)

revoke admin argument: Revoke privileges to run SQL administration API commands

Use the revoke admin argument with the **admin()** or **task()** function to revoke privileges to run SQL administration API commands.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"--revoke admin--"----------->
                     '-task--'

>--,--"--user_name--"--+-------------------------+--)--;------><
                       '-,--"--privilege_group--"-'
```

Element	Description	Key Considerations
user_name	The name of the user from which to revoke privileges.	
privilege_group	The name of the privilege group.	See SQL administration API portal: Arguments by privilege groups for a list of privilege groups.

Usage

Only user **informix**, or a user with ADMIN or GRANT permissions for SQL administration API commands, can use the **revoke admin** argument.

Use the **revoke admin** argument to revoke the privilege to run SQL administration API commands from individual users. You can revoke the privilege for a specific privilege group or revoke all privileges.

Examples

The following command revokes the privilege for running backup and restore SQL administration commands from the user Bob:

```
EXECUTE FUNCTION task("revoke admin", "Bob", "BAR");
```

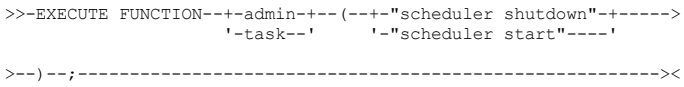
The following command revokes all privileges for running any SQL administration commands from the user Bob:

```
EXECUTE FUNCTION task("revoke admin", "Bob");
```

scheduler argument: Stop or start the scheduler (SQL administration API)

Use the scheduler argument with the **admin()** or **task()** function to start or stop the scheduler.

Syntax



Usage

Use the scheduler shutdown argument to stop the scheduler and deallocate its resources.

Use the scheduler start argument to start the scheduler.

This function has no equivalent utility command.

You can view the status of the scheduler threads with the **onstat -g dbc** command.

Example

The following example starts the scheduler after it has been shut down:

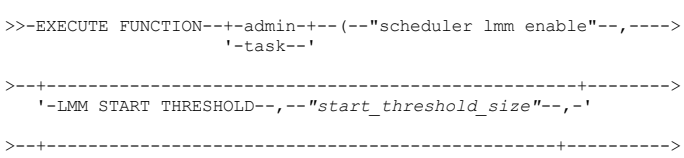
```
EXECUTE FUNCTION task("scheduler start");
```

Related reference:
onstat -g dbc command: Print dbScheduler and dbWorker thread statistics

scheduler lmm enable argument: Specify automatic low memory management settings (SQL administration API)

Use the scheduler lmm enable argument with the **admin()** or **task()** function to start automatic low memory management and to update low memory threshold settings.

Syntax



```
   '-LMM STOP THRESHOLD--,--"stop_threshold_size"--,-'

>--+-------------------------------------------------+--)--;----->
   '-LMM IDLE TIME--,--"minimum_amount_of_time"--,-'
```

Element	Description	Key Considerations
start_threshold_size	The amount of free memory that you want the database server to maintain. If the amount of memory falls below the *start_threshold_size*, the server automatically frees memory and terminates applications.	The value can be expressed as either a percentage of the value of the SHMTOTAL configuration parameter or as a specific amount. If the value is less than 50, it is considered a percentage. The resulting value of the input parameter must be more than 5 MB and less than 95 MB. The default value is 5 MB. There must be a minimum 5 MB difference between the LMM START THRESHOLD and LMM STOP THRESHOLD values
stop_threshold_size	The amount of free memory that you want the database server to have, before the server stops automatically freeing memory and terminating applications.	The value can be expressed as either a percentage of the value of the SHMTOTAL configuration parameter or as a specific amount. If the value is less than 50, it is considered a percentage. The resulting value of the input parameter must be more than 10 MB and less than 100 MB. The value must also be at least 5 MB more than the LMM START THRESHOLD. The default value is 10 MB.
minimum_amount_of_time	The amount of time in seconds that defines a session as idle	The value must be between 1 and 86400. The default value is 300 seconds.

Usage

You use the scheduler lmm disable argument with the **admin()** or **task()** function to stop the current and subsequent low memory management processes in a primary or standard database server. When low memory management is triggered, the database server performs these tasks, in order:

1. The database server terminates sessions starting one at a time from the session with largest amount of idle time and continuing as necessary to the session with smallest amount of idle time that exceeds the amount specified in the LMM IDLE TIME setting. The server stops terminating sessions when the LMM STOP THRESHOLD is reached.
2. The database server terminates sessions starting with the session using the most memory and continuing as necessary to the session using the smallest amount of memory until the LMM STOP THRESHOLD is reached.
3. The database server performs memory reconfiguration by setting the VP_MEMORY_CACHE configuration parameter to `0` and running the **onmode -F** command to free unused shared memory segments.

When the low memory management operations are complete, the low memory manager returns to monitoring mode and restores the memory configuration of the database server by setting the VP_MEMORY_CACHE configuration parameter back to its original value.

The database server stores automatic low memory management settings in the **ph_threshold** table.

You can view low memory management settings and recent activity with the **onstat -g lmm** command.

Attention: If you enable automatic low memory management and configure the database server to use a percentage of the value specified in the SHMTOTAL configuration parameter for the start and stop thresholds, use caution when changing the value of the SHMTOTAL configuration parameter. Changing the value of the SHMTOTAL configuration parameter value can cause the configuration of automatic low memory management to become invalid, forcing Informix® to use the default settings.

Example of setting low memory management threshold settings

The following example specifies that when the database server has 10 MB or less of free memory, the server will start automatic low memory management to stop applications and to free memory. The example also specifies that a session is considered idle if it has not run for 300 seconds, and the example specifies that the server will stop automatic low memory management when the server has 20 MB or more of free memory.

```
EXECUTE FUNCTION task("scheduler lmm enable",
        "LMM START THRESHOLD", "10MB",
        "LMM STOP THRESHOLD", "20MB",
        "LMM IDLE TIME", "300");
```

Example of the SHMTOTAL configuration parameter impacting low memory management threshold settings

Suppose you set the SHMTOTAL configuration parameter to `1000000` (1000 MB or 1 GB), the LMM START THRESHOLD to `2`, and the LMM STOP THRESHOLD to `3`. Because any value that is less than 50 is a percentage of the value of SHMTOTAL, the actual LMM START THRESHOLD is 20000 (20 MB) and the actual LMM STOP THRESHOLD is 30000 (30 MB).

The database server begins managing low memory when the remaining free memory is 20 MB or less and stop managing memory when the amount of free memory is 30 MB or greater.

Suppose you decide to change the value of the SHMTOTAL configuration parameter because you know now that you don't need as much memory and you want memory to be available to the operating system. You set the value of SHMTOTAL to `250000` (250 MB). This changes the actual LMM START THRESHOLD to 5000 (5 MB) and the LMM STOP THRESHOLD to 7500 (7.5 MB). The LMM STOP THRESHOLD is now invalid because there must be a minimum 5 MB difference between the LMM START THRESHOLD and LMM STOP THRESHOLD values. The LMM STOP THRESHOLD value must also be at least 10 MB.

You might have decided that a 10 MB difference is the right amount for your system. But at 5 MB, the database server could spend too much time spent on low memory management processes and this could cause performance problems.

Configure the server response when memory is critically low

scheduler lmm disable argument: Stop automatic low memory management (SQL administration API)

Use the scheduler lmm disable argument with the **admin()** or **task()** function to stop the current and subsequent invocations of automatic low memory management.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--"scheduler lmm disable"--,--->
                     '-task--'

>--)--;-------------------------------------------------------><
```

Usage

If automatic low memory management is enabled, you can disable it by specifying:

```
EXECUTE FUNCTION task("scheduler lmm disable");
```

You use the scheduler lmm enable argument with the **admin()** or **task()** function to start automatic low memory management and update threshold settings.

You can view information about automatic low memory management settings and recent activity with the **onstat -g lmm** command.

Related reference:
scheduler lmm enable argument: Specify automatic low memory management settings (SQL administration API)
onstat -g lmm command: Print low memory management information
LOW_MEMORY_MGR configuration parameter

set chunk argument: Change the status of a chunk (SQL administration API)

Use the set chunk argument with the **admin()** or **task()** function to change the status of a blobspace, dbspace, or sbspace to online or offline.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"set chunk offline"-+------>
                     '-task--'     '-"set chunk online"--'

>--,--"space_name"--,--"path_name"--,--"offset"--)--;---------><
```

Element	Description	Key Considerations
space_name	The name of the blobspace, dbspace, or sbspace.	
path_name	The disk partition or unbuffered device of the chunk.	
offset	The offset, in kilobytes, into the disk partition or unbuffered device to reach the chunk.	See admin() and task() Argument Size Specifications.

Usage

The chunk must be in a mirrored pair, or a non-primary chunk within a noncritical dbspace.

Use the set chunk offline argument to change the status of the chunk to offline.

Use the set chunk online argument to change the status of the chunk to online.

This function is equivalent to the **onspaces -s** command.

Example

The following example changes the status of a chunk to online:

```
EXECUTE FUNCTION task("set chunk online","dbs1","/dev/raw_dev1","0");
     Database selected.

(expression)  Chunk status successfully changed.
              Chunk number 2 "/dev/raw_dev1" -- Online

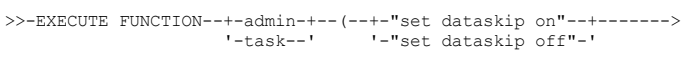
1 row(s) retrieved.
```

Related reference:
onspaces -s: Change status of a mirrored chunk

set dataskip argument: Start or stop skipping a dbspace (SQL administration API)

Use the set dataskip argument with the **admin()** or **task()** function to specify whether the database server skips a dbspace that is unavailable during the processing of a transaction.

Syntax



Element	Description	Key Considerations
dbspace	The name of the dbspace to begin or to stop skipping.	

Usage

Run this function to update the value of the DATASKIP configuration parameter, which specifies whether the database server skips a dbspace that is unavailable (for example, due to a media failure) in the course of processing a transaction.

Use the set dataskip on argument to begin skipping the specified dbspace when it is down.

Use the set dataskip off argument to stop skipping the specified dbspace.

This function is equivalent to the **onspaces -f** command.

Example

The following example skips the dbspace named **dbsp1** if it is down:

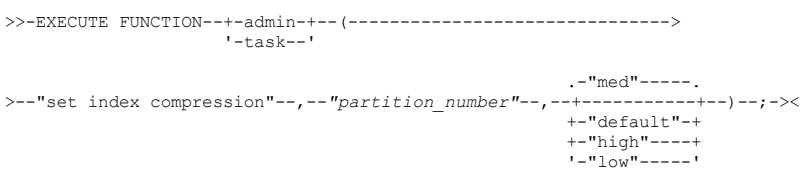
```
EXECUTE FUNCTION task("set dataskip on","dbsp1");
```

Related reference:
onspaces -f: Specify DATASKIP parameter
DATASKIP Configuration Parameter

set index compression argument: Change index page compression (SQL administration API)

Use the set index compression argument with the **admin()** or **task()** function to modify the level at which two partially used index pages are merged.

Syntax



Element	Description	Key Considerations
partition_number	The partition number.	Find the partition numbers in the **partnum** column of the **systables** system catalog table.

Usage

Use this function to adjust index page compression. The pages are merged if the data on those pages totals a set level. To optimize space and transaction processing, you can lower the compression level if your indexes grow quickly. You can increase the level if your indexes have few delete and insert operations or if batch updates are performed.

Use the low argument if you expect an index to grow quickly with frequent splits.

Use the med or default argument if an index has moderate growth or changes.

Use the high argument if an index is 90 percent or more read-only or does not have many changes.

This function is equivalent to the **onmode -C** command and the compression option of the BTSCANNER configuration parameter.

Example

The following example sets index compression for a partition to high:

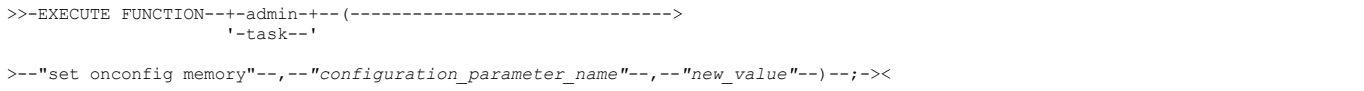
```
EXECUTE FUNCTION task("set index compression","1048611","high");
```

Related reference:
onmode -C: Control the B-tree scanner

set onconfig memory argument: Temporarily change a configuration parameter (SQL administration API)

Use the set onconfig memory argument with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in memory.

Syntax



Element	Description	Key Considerations
configuration_parameter_name	The name of a configuration parameter.	The configuration parameter must be one that you can update dynamically. The list of configuration parameters that you can update dynamically is the same as for the **onmode -wf** command.
new_value	The new value or values for the configuration parameter.	The new value or values must be valid for the configuration parameter. The format of the new value must conform exactly to the syntax for that configuration parameter.

Usage

Use this function to temporarily update the value of a configuration parameter that can be dynamically updated. The new value takes affect immediately. The new value is not written to the **onconfig** file and is lost when the database server is restarted.

This function is equivalent to the **onmode -wm** command.

Example

The following example sets the value of the DYNAMIC_LOGS configuration parameter to 2 for the current session:

```
EXECUTE FUNCTION task("set onconfig memory","DYNAMIC_LOGS","2");
```

Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters

set onconfig permanent argument: Permanently change a configuration parameter (SQL administration API)

Use the set onconfig permanent argument with the **admin()** or **task()** function to dynamically update the value of a configuration parameter in the **onconfig** file.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"set onconfig permanent"--,--"configuration_parameter_name"--,--"new_value"--)--;-><
```

Element	Description	Key Considerations
configuration_parameter_name	The name of a configuration parameter.	The configuration parameter must be one that you can update dynamically. The list of configuration parameters that you can update dynamically is the same as for the **onmode -wf** command.
new_value	The new value or values for the configuration parameter.	The new value or values must be valid for the configuration parameter. The format of the new value must conform exactly to the syntax for that configuration parameter.

Usage

Use this function to permanently update the value of a configuration parameter. The new value takes affect immediately and persists in the **onconfig** file after the server restarts.

This function is equivalent to the **onmode -wf** command.

Example

The following example sets the value of the DYNAMIC_LOGS configuration parameter to 2 in the **onconfig** file:

```
EXECUTE FUNCTION task("set onconfig permanent","DYNAMIC_LOGS","2");
```

Related reference:
onmode -wf, -wm: Dynamically change certain configuration parameters

set sbspace accesstime argument: Control access time tracking (SQL administration API)

Use the set sbspace accesstime argument with the **admin()** or **task()** function to start or stop tracking the time of access for all smart large objects stored in the sbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--+-"set sbspace accesstime off"-+--,--"sbspace"--)--;-------><
   '-"set sbspace accesstime on"--'
```

Element	Description	Key Considerations
sbspace	The name of the sbspace.	

Usage

Use the set sbspace accesstime off argument to turn off tracking of access times.

Use the set sbspace accesstime on argument to turn on tracking of access times for all smart large objects stored in the sbspace.

This function is equivalent to the **onspaces -ch** command.

Example

The following example turns off tracking of access times for the sbspace named **sbsp1**:

```
EXECUTE FUNCTION task("set sbspace accesstime off","sbsp1");
```

Related reference:
onspaces -ch: Change sbspace default specifications
create sbspace with accesstime argument: Create an sbspace that tracks access time (SQL administration API)

set sbspace avg_lo_size argument: Set the average size of smart large objects (SQL administration API)

Use the set sbspace avg_lo_size argument with the **admin()** or **task()** function to specify an expected average size of the smart large objects in the specified sbspace so that the database server can calculate the size of the metadata area.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"set sbspace avg_lo_size"--,--"sbspace"--,--"average_size"--->

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
sbspace	The name of the sbspace.	
average_size	The average size, in kilobytes, of the smart large object stored in the sbspace.	Windows: 4 to 2**31 UNIX: 2 to 2**31

Usage

This function is equivalent to the **onspaces -ch** command.

Example

The following example sets the expected average size of smart large objects in the sbspace named **sbsp1** to 8 KB:

```
EXECUTE FUNCTION task("set sbspace avg_lo_size","sbsp1","8");
```

Related reference:
onspaces -ch: Change sbspace default specifications

set sbspace logging argument: Change the logging of an sbspace (SQL administration API)

Use the set sbspace logging argument with the **admin()** or **task()** function to specify whether the database server logs changes to the user data area of the sbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--+-"set sbspace logging on"--+--,--"sbspace"--)--;----------><
   '-"set sbspace logging off"-'
```

Element	Description	Key Considerations
sbspace	The name of the sbspace.	

Usage

Use the set sbspace logging on argument to log changes to the user data area of the sbspace.

Use the set sbspace logging off argument to not log changes to the user data area of the sbspace.

This function is equivalent to the **onspaces -ch** command.

Example

The following example starts sbspace logging for an sbspace named **sbsp1**:

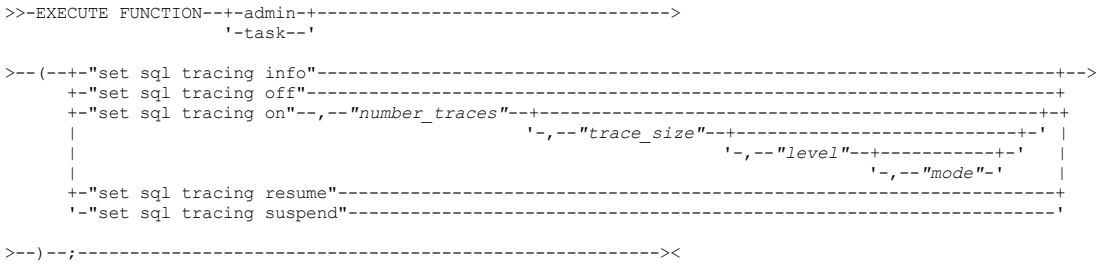
```
EXECUTE FUNCTION task("set sbspace logging on","sbsp1");
```

Related reference:
onspaces -ch: Change sbspace default specifications

set sql tracing argument: Set global SQL tracing (SQL administration API)

Use the set sql tracing argument with the **admin()** or **task()** function to set global SQL tracing.

Syntax



Element	Description	Key Considerations
level	The tracing level. The default is low.	Possible values are: • low • med • high
mode	Whether all or selected users are traced.	Possible modes are: • global • user
number_traces	The number of SQL statements to trace. The default value is 1000.	
trace_size	The number of KB for the size of the trace buffer. If this buffer size is exceeded, the database server discards saved data. The default size is 2 KB.	

Usage

Use this function to reset the value of the SQLTRACE configuration parameter.

Use the set sql tracing info argument to display the state of global SQL tracing.

Use the set sql tracing off argument to turn off global SQL tracing.

Use the set sql tracing on argument to turn on global SQL tracing. Optionally specify the tracing level and mode or change the size of the trace buffer.

- Use the low argument to capture statement statistics, statement text, and statement iterators.
- Use the med argument to capture all of the information included in low-level tracing, plus table names, the database name, and stored procedure stacks.
- Use the high argument to capture all of the information included in medium-level tracing, plus host variables.
- Use the global argument to enable tracing for all users.
- Use the user argument to enable tracing for those users who have tracing enabled by the set sql tracing user argument.

Use the set sql tracing resume argument to restart SQL tracing when it is suspended.

Use the set sql tracing suspend argument to pause SQL tracing without deallocating any resources.

Example

The following example starts a high level of global tracing for 1500 SQL statements into a 4 KB trace buffer:

```
EXECUTE FUNCTION task("set sql tracing on","1500","4","high","global");
```

The following example pauses SQL tracing:

```
EXECUTE FUNCTION task("set sql tracing suspend");
```

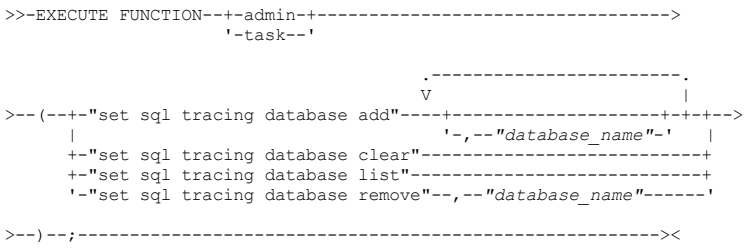
SQLTRACE configuration parameter
onstat -g spf: Print prepared statement profiles

set sql tracing database argument: Change database tracing (SQL administration API)

Use the set sql tracing database argument with the **admin()** or **task()** function to start or stop tracing for a database, or list which databases are being traced.

Syntax



Element	Description	Key Considerations
database_name	The name of the database.	Specify one database name.

Usage

Use the set sql tracing database add argument to specify tracing for one or more databases, rather than for all databases. The default is all databases. Specify up to six arguments in a single **admin()** or **task()** function. The maximum number of database names that can be set is 16.

Use the set sql tracing database clear argument to clear all databases from the list of databases being traced. Returns tracing back to the default of all databases.

Use the set sql tracing database list argument to list the databases that are being traced.

Use the set sql tracing database remove argument to remove a single database from the list of databases being traced.

When you use the set sql tracing database argument, you can specify only the name of one database. While you can have a maximum of 16 database names, you must specify each additional database name in separate function calls. Each time you call the function, the function adds another database to the list, until the list contains 16 databases.

Example

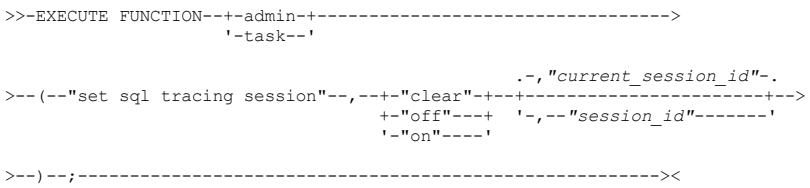
The following example sets SQL tracing for three databases with the names **db1**, **db2** and **db3**:

```
EXECUTE FUNCTION task("set sql tracing database add","db1");
EXECUTE FUNCTION task("set sql tracing database add","db2");
EXECUTE FUNCTION task("set sql tracing database add","db3");
```

set sql tracing session argument: Control tracing for a session (SQL administration API)

Use the set sql tracing session argument with the **admin()** or **task()** function to change SQL tracing for the current session.

Syntax



Element	Description	Key Considerations
current_session_id	The ID of the current session. This is the default session ID.	
session_id	The ID of the session to which this command applies.	

Usage

Use the clear argument to clear any global tracing overrides. The session will conform to the global tracing policy.

Use the off argument to turn off tracing for the session, even if the global tracing policy is set to enable tracing.

Use the on argument to turn on tracing for the session, even if the global tracing policy is set to disable tracing.

Example

The following example stops tracing for the current session:

```
EXECUTE FUNCTION task("set sql tracing session","off");
```

set sql tracing user argument: Control tracing for users (SQL administration API)

Use the set sql tracing user argument with the **admin()** or **task()** function to change SQL tracing for users.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                     '-task--'

>--(--+-"set sql tracing user add"--,--"user_name"----+--)--;--><
      +-"set sql tracing user clear"-------------------+
      +-"set sql tracing user list"--------------------+
      '-"set sql tracing user remove"--,--"user_name"-'
```

Element	Description	Key Considerations
user_name	The name of the user.	

Usage

Use the set sql tracing user add argument to specify tracing for a specific user.

Use the set sql tracing user clear argument to remove all users from the tracing list.

Use the set sql tracing user list argument to list the users that are being traced.

Use the set sql tracing user remove argument to remove a single user from the list of users being traced.

Example

The following example stops tracing SQL statements for the user named **fred**:

```
EXECUTE FUNCTION task("set sql tracing user remove","fred");
```

set sql user tracing argument: Set global SQL tracing for a user session (SQL administration API)

Use the set sql user tracing argument with the **admin()** or **task()** function to set the mode of global SQL tracing for a specified user session.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+----------------------------------->
                     '-task--'

>--(--+-"set sql user tracing clear"-+--,--"session_id"--)--;--><
      +-"set sql user tracing off"---+
      '-"set sql user tracing on"----'
```

Element	Description	Key Considerations
session_id	The ID for the session.	

Usage

Use the set sql user tracing clear to clear user tracing flags for the specified user session so that it adheres to the global tracing policy.

Use the set sql user tracing off to disable SQL tracing for a user session even if the global mode is ON.

Use the set sql user tracing on to enable user SQL tracing for a user session. Even if the global tracing mode is OFF, SQL statements for this user session are traced.

Example

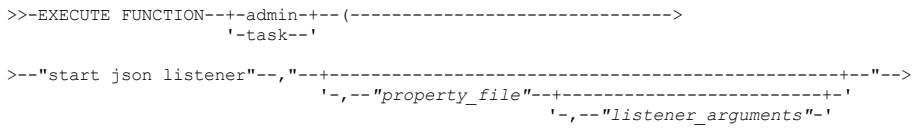
The following example starts tracing for the session with the ID of `18`:

```
EXECUTE FUNCTION task("set sql user tracing on","18");
```

start json listener argument: Start the MongoDB API wire listener (deprecated)

Use the start json listener argument with the **admin()** or **task()** function to start the MongoDB API wire listener.

Syntax



Element	Description	Key Considerations
property_file	The name of the wire listener configuration file to use instead of the default.	The *property_file* is optional. The default wire listener configuration file is in $INFORMIXDIR/etc/jsonListener.properties.
listener_arguments	The command line argument to pass to the wire listener.	

Usage

The start json listener argument starts the MongoDB API wire listener.

Example

In this example, the MongoDB API wire listener is started by using the mycustom.properties file instead of the default jsonListener.properties file:

```
EXECUTE FUNCTION task("start json listener", "mycustom.properties");
```

In this example, the MongoDB API wire listener is started by using mycustom.properties file instead of the default jsonListener.properties, the port is specified as 27018, and the logging level is set as debug:

```
EXECUTE FUNCTION task("start json listener", "mycustom.properties",
   "-port 27018 -loglevel debug");
```

Related information:
Starting the wire listener
Wire listener command line options

start listen argument: Start a listen thread dynamically (SQL administration API)

Use the start listen argument with the **admin()** or **task()** function to start an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.

Syntax

Element	Description	Key Considerations
server_name	The name of the database server for which you want to start a listen thread.	

Usage

The definition of the listen thread must exist in the **sqlhosts** file for the server. If the definition of the listen thread does not exist in the **sqlhosts** file, you must add it before you can start the listen thread dynamically. For information on adding listen threads, see the *IBM® Informix® Administrator's Guide*.

This function does not update the **sqlhosts** file.

This function is equivalent to the **onmode -P start** *server_name* command.

Example

The following command starts a new listen thread for a server named **ids_serv2**:

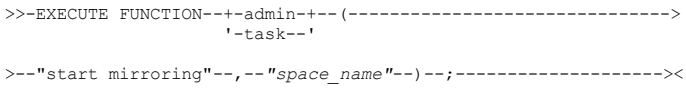
```
EXECUTE FUNCTION task("start listen","ids_serv2");
```

Related reference:
onmode -P: Start, stop, or restart a listen thread dynamically
stop listen argument: Stop a listen thread dynamically (SQL administration API)
restart listen argument: Stop and start a listen thread dynamically (SQL administration API)

start mirroring argument: Starts storage space mirroring (SQL administration API)

Use the start mirroring argument with the **admin()** or **task()** function to start mirroring for a specified dbspace, blobspace, or sbspace.

Syntax



Element	Description	Key Considerations
space_name	The name of the blobspace, dbspace, or sbspace.	

Usage

This function is equivalent to the **onspaces -m** command.

Example

The following example starts mirroring for the dbspace named **dbsp1**:

```
EXECUTE FUNCTION task("start mirroring","dbsp1");
```

Related reference:
onspaces -m: Start mirroring

statement cache enable argument: Enable the SQL statement cache (SQL administration API)

Use the statement cache enable argument with the **admin()** or **task()** function to enable the statement cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"statement cache enable"-+----->
                     '-task--'
>--)--;-------------------------------------------------------------><
```

Usage

This function is equivalent to the **onmode -e enable** command.

statement cache flush argument: Flush the SQL statement cache (SQL administration API)

Use the statement cache flush argument with the **admin()** or **task()** function to flush the statement cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"statement cache flush"-+----->
                     '-task--'
>--)--;-------------------------------------------------------------><
```

Usage

This function is equivalent to the **onmode -e flush** command.

statement cache hits argument: Specify the number of hits in the SQL statement cache (SQL administration API)

Use the statement cache hits argument with the **admin()** or **task()** function to specify the number of hits in the SQL statement cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"statement cache hits", "<numhits>"-+----->
                     '-task--'
>--)--;-------------------------------------------------------------------><
```

Usage

This function is equivalent to the **onmode -W STMT_CACHE_HITS** command.

statement cache nolimit argument: Control whether to insert qualified statements into the SQL statement cache (SQL administration API)

Use the statement cache nolimit argument with the **admin()** or **task()** function to control whether to insert statements into the SQL statement cache after its size is greater than the STMT_CACHE_SIZE value.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"statement cache nolimit <0/1>"-+----->
                     '-task--'
>--)--;-------------------------------------------------------------------><
```

Usage

This function is equivalent to the **onmode -W STMT_CACHE_NOLIMIT {0|1}** command.

statement cache off argument: Disable the SQL statement cache (SQL administration API)

Use the statement cache off argument with the **admin()** or **task()** function to turn off the SQL statement cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"statement cache off"-+----->
                    '-task--'
>--)--;-------------------------------------------------------><
```

Usage

This function is equivalent to the **onmode -e off** command.

statement cache save argument: Save the SQL statement cache (SQL administration API)

Use the statement cache save argument with the **admin()** or **task()** function to save the statement cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"statement cache save"-+----->
                    '-task--'
>--)--;-------------------------------------------------------><
```

Usage

statement cache save is used to:

- Lock the Statement Cache
- Drop sysadmin:statement_cache table if it exists
- Create new sysadmin:statement_cache table
- Copy each entry from the Statement Cache and insert into the sysadmin:statement_cache table
  Note: If cache entry is Locked, the query plan will be preserved so that it can persist as-is when being restored.
  Note: If cache entry is Locked and has STMT_CACHE_QUERY_PLAN enabled, the current query plan will be stored in text form so it can persist as-is when being restored.
- Unlock the Statement Cache

statement cache restore argument: Restore the SQL statement cache (SQL administration API)

Use the statement cache restore argument with the **admin()** or **task()** function to restore the statement cache.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(--+-"statement cache restore"-+----->
                    '-task--'
>--)--;-------------------------------------------------------><
```

Usage

statement cache restore is used to:

- Lock the Statement Cache
- Read each row from sysadmin: statement_cache table
- Prepare the statement for the saved row so that statement will be inserted into the cache
  Note: If cache entry is Locked and has STMT_CACHE_QUERY_PLAN enabled, then it will be revived in its saved form.
  Note: If cache entry was Locked and had STMT_CACHE_QUERY_PLAN enabled when it was saved, then the text form of the query plan will be restored.
- Unlock the Statement Cache

stop json listener: Stop the wire listener (deprecated)

Use the stop json listener argument with the **admin()** or **task()** function to stop the wire listener.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
```

```
                    '-task--'

>--"stop json listener"--,"--+-------------------------------------------------+--"-->
                            '-,--"property_file"--+-------------------------+-'
                                                  '-,--"listener_arguments"-'

>--)--;-----------------------------------------------------><
```

Element	Description	Key Considerations
property_file	The name of the wire listener configuration file to use instead of the default.	The *property_file* is optional. The default wire listener configuration file is in $INFORMIXDIR/etc/jsonListener.properties.
listener_arguments	The command line argument to pass to the wire listener.	

Usage

The stop json listener argument stops the wire listener.

Example

In the following example, the wire listener is stopped by using the mycustom.properties file instead of the default jsonListener.properties file:

```
EXECUTE FUNCTION task("stop json listener", "mycustom.properties");
```

In this example, the wire listener is stopped by using mycustom.properties file instead of the default jsonListener.properties, and a command line argument is passed to the wire listener:

```
EXECUTE FUNCTION task("stop json listener", "mycustom.properties", "-port 27018");
```

Related information:
Wire listener command line options
Stopping the wire listener

stop listen argument: Stop a listen thread dynamically (SQL administration API)

Use the stop listen argument with the **admin()** or **task()** function to stop an existing listen thread for a SOCTCP or TLITCP network protocol without interrupting existing connections.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"stop listen"--,--"server_name"--)--;----------------------><
```

Element	Description	Key Considerations
server_name	The name of the database server for which you want to stop a listen thread.	

Usage

The definition of the listen thread must exist in the **sqlhosts** file.

This function does not update the **sqlhosts** file.

This function is equivalent to the **onmode -P stop** *server_name* command.

Example

The following command stops a listen thread for a server named **ids_serv3**:

```
EXECUTE FUNCTION task("stop listen","ids_serv3");
```

Related reference:
onmode -P: Start, stop, or restart a listen thread dynamically
start listen argument: Start a listen thread dynamically (SQL administration API)
restart listen argument: Stop and start a listen thread dynamically (SQL administration API)

stop mirroring argument: Stops storage space mirroring (SQL administration API)

Use the stop mirroring argument with the **admin()** or **task()** function to stop mirroring for a specified dbspace, blobspace, or sbspace.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"stop mirroring"--,--"space_name"--)--;---------------------><
```

Element	Description	Key Considerations
space_name	The name of the blobspace, dbspace, or sbspace.	

Usage

This function is equivalent to the **onspaces -r** command.

Example

The following example stops mirroring for the dbspace with the name of **dbsp1**:

```
EXECUTE FUNCTION task("stop mirroring","dbsp1");
```

Related reference:
onspaces -r: Stop mirroring

storagepool add argument: Add a storage pool entry (SQL administration API)

Use the storagepool add argument with the **admin()** or **task()** function to add an entry to the *storage pool* (a collection of available raw devices, cooked files, or directories that Informix® can use to automatically add space to an existing storage space).

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--storagepool add--"--,--"path_name"------------------------>

>--,--"begin_offset"--,--"total_size"--,--"chunk_size"--,--"priority"-->

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
path_name	The path for the file, directory, or device that the server can use when additional storage space is required.	You do not need to add a final slash (“/”) to a directory name. You can use an environment variable in the path if the variable is in your environment when the **oninit** command runs.
begin_offset	The offset in kilobytes into the device where Informix can begin allocating space.	If you specified a path to a directory, you must specify `0` as the offset.
total_size	The total space available to Informix in this entry. The server can allocate multiple chunks from this amount of space.	Be sure to specify `0` for the total size of a directory. If you specify a value that is not zero for a directory, the SQL administration API command returns an error. If you specify `0` for a file or device, the server will allocate one extendable chunk from the entry.
chunk_size	The minimum size of a chunk that can be allocated from the device, file, or directory.	The smallest chunk that you can create is 1000 K. Therefore, the minimum chunk size that you can specify is 1000 K. See admin() and task() Argument Size Specifications.
priority	The priority of the directory, file, or device when the server searches through the storage pool for space. • 1 = High priority • 2 = Medium priority • 3 = Low priority	The server tries to allocate space from a high-priority entry before it allocates space from a lower priority entry.

Usage

The server uses entries in the storage pool if necessary to add a new chunk to a storage space.

When you add an entry to the storage pool, you might want some control over how that entry is used. For example, to reduce the number of chunks in an instance, you might want only large chunks of space to be allocated from a particular raw device, and might not want the chunks to be extendable. In this case, configure the chunk size for that storage pool entry to be large.

You can add the following types of entries to the storage pool:

- A fixed-length raw device
- A fixed-length cooked file
- An extendable raw device (for extending the size of a chunk)
- An extendable cooked file (for extending the size of a chunk)
- A directory

A storage pool entry that is a directory is always categorized as extendable, because it does not have a total size. If new chunks are automatically created in the directory, the server marks those chunks as extendable. When you add a storage pool entry that is a directory, you might want a small chunk size, because the server can extend any chunk created in the directory and smaller chunk sizes can reduce the amount of wasted space in the instance.

If a storage pool entry is on a High-Availability Data Replication (HDR) primary server, the same path in the entry must be available on all secondary servers in the HDR cluster.

The default units for sizes and offsets are kilobytes. However, you can specify information in any of the ways shown in the following examples:

- "100000"
- "100000 K"
- "100 MB"
- "100 GB"
- "100 TB"

Example: Adding a storage pool entry for a directory

The following command adds a directory named /region2/dbspaces with a beginning offset of 0, a total size of 0, an initial chunk size of 20 megabytes, and a high priority:

```
DATABASE sysadmin;
EXECUTE FUNCTION task("storagepool add", "/region2/dbspaces", "0", "0",
"20000", "1");
```

Example: Adding a storage pool entry for a fixed-length raw device

The following command adds a fixed-length raw device with the path name /dev/raw/device1 and a total of 500 megabytes of space to the storage pool. The command specifies a beginning offset of 50 megabytes, a total size of 10 gigabytes, a minimum of 100 megabytes to allocate to a chunk, and a low priority.

```
EXECUTE FUNCTION task("storagepool add", "/dev/rawdevice1", "50 MB",
 "10 GB", "100 MB", "3");
```

Example: Adding a storage pool entry for a fixed-length cooked file

The following command adds a fixed-length cooked file and 1 gigabyte of space to the storage pool. The command specifies a beginning offset of 0, a total size of 1000000 kilobytes, a minimum of 50000 kilobytes to allocate to a chunk, and a medium priority:

```
EXECUTE FUNCTION task("storagepool add", "/ifmx_filesystem/storage/cooked7",
 "0", "1000000", "50000", "2");
```

When adding this entry, the server tries to increase the size of the cooked7 file to 1 gigabyte. If the server cannot increase the size because the file system is full, the server returns an error message and does not add the entry to the storage pool.

Informix uses part of the cooked file initially, but can use more of the device as necessary as spaces fill.

Example: Adding a storage pool entry for an extendable cooked file

The following command adds a cooked file with the path name /ifmx/CHUNKFILES/cooked2. If the server uses this entry, the server creates one chunk with an initial size of 1 GB, and the server automatically marks the chunk as extendable.

```
EXECUTE FUNCTION task("storagepool add", "/ifmx/CHUNKFILES/cooked2",
 "0", "0", "1 GB", "2");
```

Example: Adding a storage pool entry with an environment variable in the path

The following example includes an environment variable in the path. The variable was present in the server environment when the **oninit** command ran.

```
EXECUTE FUNCTION task("storagepool add", "$DBSDIR/chunk1",
 "0", "100000", "20000", "2");
```

Related reference:
storagepool modify argument: Modify a storage pool entry (SQL administration API)
storagepool delete argument: Delete one storage pool entry (SQL administration API)

Related information:
Automatic space management

storagepool delete argument: Delete one storage pool entry (SQL administration API)

Use the storagepool delete argument with the **admin()** or **task()** function to delete an entry from the storage pool.

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--storagepool delete--"--,--"--entry_id--"--)--;----------><
```

Element	Description	Key Considerations
entry_id	The ID of the storage pool entry.	The **storagepool** table in the **sysadmin** database contains a column that shows the ID of each entry in the storage pool.

Usage

Delete a storage pool entry if you do not want the server to continue to use the entry when expanding a storage space.

To delete all storage pool entries, storage pool entries that have a status of `Full`, or storage pool entries that have a status of `Error`, use the SQL administration API storagepool purge command. (The **storagepool** table in the **sysadmin** database contains a column that shows the status of each entry in the storage pool.)

Example

The following command deletes the storage pool entry with an entry id of 13:

```
EXECUTE FUNCTION task("storagepool delete", "13");
```

Related reference:
storagepool add argument: Add a storage pool entry (SQL administration API)
storagepool modify argument: Modify a storage pool entry (SQL administration API)
storagepool purge argument: Delete storage pool entries (SQL administration API)
Related information:
Automatic space management

storagepool modify argument: Modify a storage pool entry (SQL administration API)

Use the storagepool modify argument with the **admin()** or **task()** function to modify an entry for a directory, cooked file, or raw device that Informix® can use when additional storage space is required.

Syntax

```
>>-EXECUTE FUNCTION--+-admin-+--(------------------------------>
                     '-task--'

>--"--storagepool modify--"--,--"--entry_id--"--,--------------->

>--"new_total_size"--,--"new_chunk_size"--,--"new_priority"----->

>--)--;-------------------------------------------------------><
```

Element	Description	Key Considerations
entry_id	The ID of the storage pool entry.	The **storagepool** table in the **sysadmin** database contains a column that shows the ID of each entry in the storage pool.
new_total_size	The new amount of total space available to Informix in this entry. The server can allocate multiple chunks from this amount of space.	Be sure to specify `0` for the total size of a directory. If you specify a value that is not zero for a directory, the SQL administration API command returns an error. If you specify `0` for a file or device, the server allocates one extendable chunk from the entry.
new_chunk_size	The minimum size of a chunk that can be allocated from the device, file, or directory.	The smallest chunk that you can create is 1000 K. Therefore, the minimum chunk size that you can specify is 1000 K. See admin() and task() Argument Size Specifications.

Element	Description	Key Considerations
new_priority	The priority of the directory, file, or device when the server searches through the storage pool for space. • 1 = High priority • 2 = Medium priority • 3 = Low priority	The server attempts to allocate space from a high-priority entry before it allocates space from a lower priority entry.

Usage

Sometimes you might want to change a storage pool entry. For example, you might want to increase the total size of the storage pool when it runs out of space, or you might want to change the chunk size or the priority. When you change the entry, include the total size, chunk size, and priority even if you do not want to change all of these values.

You cannot modify the path or the beginning offset of a storage pool entry. If you want to change either of those values, you must delete the storage pool entry and add an entry with the new path or beginning offset.

If a storage pool entry is on a High-Availability Data Replication (HDR) primary server, the same path in the entry must be available on all secondary servers in the HDR cluster.

The default units for storage pool sizes and offsets are kilobytes. However, you can specify information in any of the ways shown in the following examples:

- "100000"
- "100000 K"
- "100 MB"
- "100 GB"
- "100 TB"

Examples

The following command changes the total size, chunk size, and priority of the storage pool entry that has an ID of 4 to 10 gigabytes, 10 megabytes, and a medium priority.

```
EXECUTE FUNCTION task("storagepool modify", "4", "10 GB", "10000", "2");
```

Suppose that you add an entry to the storage pool and the entry has a path of (/dev/IDS/chunk2), an offset of 0, a total size of 100 megabytes, a minimum chunk size of 100 megabytes, and a priority of 2. Before Informix allocates any space from this entry, you use **onspaces** to manually add a 50 megabyte chunk with the same path (/dev/IDS/chunk2), and an offset of 50 megabytes. The server only detects the overlap when it attempts to use this entry to automatically create a chunk. At that time, the server marks the entry with an "Error" status and attempts to use another entry to create the chunk.

You can correct the problem by changing the total size of the storage pool entry (for example, for entry 2), to 50 megabytes and by changing the minimum chunk size of the entry to 50 megabytes, as follows:

```
EXECUTE FUNCTION task("storagepool modify", "2", "50 MB", "50 MB", "2");
```

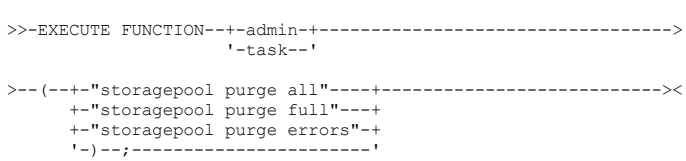
Related information:
Automatic space management

storagepool purge argument: Delete storage pool entries (SQL administration API)

Use the storagepool purge argument with the **admin()** or **task()** function to delete all storage pool entries, storage pool entries that have a status of `Full`, or storage pool entries that have a status of `Error`.



Usage

Use the storagepool purge all argument to delete all entries in the storage pool.

Use the storagepool purge full argument to delete all storage pool entries that have a status of `Full`.

Use the storagepool purge errors argument to delete all storage pool entries that have a status of `Error`.

The **storagepool** table in the **sysadmin** database contains a column that shows the status of each entry in the storage pool.

Example

The following command deletes all storage pool entries that have a status of `Full`:

```
EXECUTE FUNCTION task("storagepool purge full");
```

Related reference:
storagepool add argument: Add a storage pool entry (SQL administration API)
storagepool modify argument: Modify a storage pool entry (SQL administration API)
storagepool delete argument: Delete one storage pool entry (SQL administration API)
Related information:
Automatic space management

Table and fragment pfsc_boost argument: Enable or disable a boosted partition free space cache (PFSC)

You can enable and disable a boosted partition free space cache for a table or fragment using SQL administration API **admin()** or **task()** functions and arguments.

The built-in SQL administration API **admin()** or **task()** functions are defined in the **sysadmin** database of each Informix® instance. By default, only user **informix** can invoke these functions. If Connect privilege on the **sysadmin** database is granted to user **root** or to **DBSA** group members, they too can invoke the SQL administration API **admin()** or **task()** functions when they are connected directly or remotely to the **sysadmin** database.

The SQL administration API **admin()** or **task()** command arguments that you can use to enable or disable boosted PFSCs in tables and table fragments are:

- **table pfsc_boost enable**: Use the *"table pfsc_boost enable"* sysadmin task() or admin() command to create a boosted PFSC for a table. For example:

  ```
  execute function task("table pfsc_boost enable", "<table name>", "<database name>");
  ```

- **fragment pfsc_boost enable**: Use the *"fragment pfsc_boost enable"* sysadmin task() or admin() command to create a boosted PFSC for a specific fragment. For example:

  ```
  execute function task("fragment pfsc_boost enable", "<partnum>");
  ```

- **table pfsc_boost disable**: Use the *"table pfsc_boost disable"* sysadmin task() or admin() command to disable a boosted PFSC for a table. For example:

  ```
  execute function task("table pfsc_boost disable", "<table name>", "<database name>");
  ```

- **fragment pfsc_boost disable**: Use the *"fragment pfsc_boost disable"* sysadmin task() or admin() command to disable a boosted PFSC for a specific fragment. For example:

  ```
  execute function task("fragment pfsc_boost disable", "<partnum>");
  ```

Note: Boosted partition free space caches are re-created automatically in shared memory on server restart.
For more information, see Boosted Partition Free Space Caches (PFSC).

Table and fragment compress and uncompress operations (SQL administration API)

You can compress and uncompress the data in a table or in table fragments with SQL administration API **admin()** or **task()** functions and arguments. Compression operations apply only to the contents of data rows and the images of those data rows that appear in logical log records.

The built-in SQL administration API **admin()** or **task()** functions are defined in the **sysadmin** database of each Informix® instance. By default, only user **informix** can invoke these functions. If Connect privilege on the **sysadmin** database is granted to user **root** or to **DBSA** group members, they too can invoke the SQL administration API **admin()** or **task()** functions when they are connected directly or remotely to the **sysadmin** database.

The SQL administration API **admin()** or **task()** command arguments that you can use for compress and uncompress operations in tables and table fragments are:

table *compression parameters*
: Performs various compression operations to all fragments of a specified table. For more information, see table or fragment arguments: Compress data and optimize storage (SQL administration API).

fragment *compression parameters*
: Performs various compression operations to a single fragment or a specified set of fragments that belong to a specific table. For more information, see table or fragment arguments: Compress data and optimize storage (SQL administration API).

compression purge_dictionary
: Deletes all inactive compression dictionaries or all inactive compression dictionaries that were created before a date that you specify. For more information, see purge compression dictionary arguments: Remove compression dictionaries (SQL administration API).

Table and fragment compression operations include creating compression dictionaries, estimating compression ratios, compressing data in tables and table fragments, consolidating free space (repacking), returning free space to a dbspace (shrinking), uncompressing data, and deleting individual table and fragment compression dictionaries.

When you run SQL administration API compression and uncompression commands, you compress and uncompress both row data and simple large objects in dbspaces. You can also specify whether to compress or uncompress only row data or only simple large objects in dbspaces.

An **admin()** command returns an integer; a **task()** command returns a string.

For information on the types of data that you can compress, compression ratios, compression estimates, and compression dictionaries, as well as procedures for using compression command parameters, see Compression in the *IBM® Informix Administrator's Guide*. For information on utilities and the **sysmaster** table and view that display compression information, see syscompdicts_full.

You can also compress, optimize storage, and estimate compression benefits for B-tree indexes. See index compress repack shrink arguments: Optimize the storage of B-tree indexes (SQL administration API) and index estimate_compression argument: Estimate index compression (SQL administration API).

- table or fragment arguments: Compress data and optimize storage (SQL administration API)
  Use SQL administration API functions with **table** or **fragment** arguments to create compression dictionaries, to estimate compression ratios, to compress data in tables and table fragments, to consolidate free space (repack), to return free space to a dbspace (shrink), to uncompress data, and to delete compression dictionaries.
- Output of the estimate compression operation (SQL administration API)
  After you run the command for estimating compression ratios, the database server displays information that shows the estimate of the compression ratio that can be achieved, along with the currently achieved compression ratio (if it exists).
- purge compression dictionary arguments: Remove compression dictionaries (SQL administration API)
  Call the **admin()** or **task()** function with the compression purge_dictionary initial command to delete all inactive compression dictionaries or all inactive compression dictionaries that were created for a compressed table or fragment before a specified date. You must uncompress tables and fragments, which makes the dictionaries inactive, before you delete any compression dictionaries that were created for the tables and fragments.

table or fragment arguments: Compress data and optimize storage (SQL administration API)

Use SQL administration API functions with **table** or **fragment** arguments to create compression dictionaries, to estimate compression ratios, to compress data in tables and table fragments, to consolidate free space (repack), to return free space to a dbspace (shrink), to uncompress data, and to delete compression dictionaries.

When you run SQL administration API compression and uncompression commands, you compress and uncompress row data and simple large objects in dbspaces. You can also specify whether to compress or uncompress only row data or only simple large objects in dbspaces.

Command arguments

The following table describes each argument.

Table 1. Arguments for Compress and Uncompress Operations

Argument	Description
blobs	Specifies that you want to compress or uncompress only simple large objects in dbspaces and not row data.
compress	Compresses all existing rows in-place, without moving them (without repacking the table). This option automatically compresses row data and simple large objects in dbspaces. To compress only row data or only simple large objects in dbspaces, also use the **rows** or **blobs** element. If a compression dictionary for the target table or fragment does not exist, the compress operation also creates the dictionary.
create_dictionary	Builds a compression dictionary, which is a library of frequently occurring patterns and the symbol numbers that replace them in compressed rows. After a dictionary is created, any newly inserted or updated rows will be compressed if they are compressible. Existing rows are not compressed.
estimate_compression	Estimates both a new compression ratio and a current ratio. The current ratio is 0.0 percent if the table is not compressed.
parallel	Runs the compress, repack, update_ipa, or uncompress operation in parallel. A thread is started for each fragment of the table or fragment list and the operation is run in parallel across those fragments.
purge_dictionary	Deletes an inactive compression dictionary after you uncompress a table or fragment.
repack	Consolidates free space by moving data to the front of the fragment or table. Because the repack operation moves rows while the fragment is online, other queries that access the fragment that are using an isolation level below Repeatable Read might occasionally find the same row twice or miss finding a row. To avoid this possibility, use the Repeatable Read isolation level for concurrent queries; or, instead of using the **repack** argument, use the **repack_offline** argument.
repack_offline	Consolidates free space by moving data to the front of the table or fragment, while holding an exclusive lock on the table or fragment. This operation prevents all other access to data until the operation is completed.
rows	Specifies that you want to compress or uncompress only row data and not simple large objects in dbspaces.
shrink	Returns free space at the end of a fragment or table to the dbspace, thus reducing the total size of the fragment or table.
uncompress	Deactivates compression for new INSERT and UPDATE operations, uncompresses all compressed rows, and deactivates the compression dictionary. This operation also allocates new pages for a fragment and moves uncompressed rows that no longer fit on their original pages to the new pages. Because this operation moves rows while the fragment is online, other queries that access the fragment that are using an isolation level below the Repeatable Read isolation level might occasionally find the same row twice or miss finding a row. To avoid this possibility, use the Repeatable Read isolation level for concurrent queries, or instead of using the **uncompress** argument, use the **uncompress_offline** argument. This option automatically uncompresses row data and simple large objects in dbspaces. To compress only row data or only simple large objects in dbspaces, also use the **rows** or **blobs** element.
uncompress_offline	Deactivates compression for new INSERT and UPDATE operations, uncompresses all compressed rows, and deactivates the compression dictionary, while holding an exclusive lock on the fragment. This prevents all other access to the fragment data until the operation is completed. This operation also allocates new pages for a fragment and moves uncompressed rows that no longer fit on their original pages to the new pages.
update_ipa	Removes outstanding in-place alter operations for the specified table or fragments.

Command elements

The following tables show the elements that you can use in commands.

Table 2. Table compression and storage optimization command elements

Element	Description	Key Considerations
database_name	The name of the database that contains the specified table.	Optional. If you do not specify a *database*, Informix® uses the current database. If you enter a database name, you must use the same uppercase or lowercase letters that are in system catalog tables.
owner	The authorization identifier of the owner of the database that contains the specified table.	Optional. If you do not specify an *owner*, Informix uses the current owner. If you enter an owner name, you must use the same uppercase or lowercase letters that are in system catalog tables.
table_name	The name of the table that contains the data.	You must use the same uppercase or lowercase letters that are in system catalog tables.

Table 3. Fragment compression and storage optimization command elements

Element	Description	Key Considerations
partition_number	A space-separated list of partition numbers that belong to the same table.	

Usage

Informix uses the compression dictionary to compress data.

After you run a **compress** command on a table or fragment, Informix automatically compresses any new rows that you add to the table or fragment. If the table or fragment contains more than 2000 rows when you run the **compress** command, a compression dictionary is built and all the rows are compressed. If the table or fragment contains fewer than 2000 rows when you run the compression command, the table or fragment is enabled for automatic compression. After 2000 rows are inserted, a compression dictionary is created and all rows after the initial 2000 rows are compressed. To compress the initial 2000 rows, run the **compress** command again.

If your data changes significantly, the compression dictionary might not be effective. In this situation, uncompress and then compress again.

You can cancel a command with a **compress** or **uncompress** argument, for example, by typing CTRL-C in DB-Access. You can reissue commands with **repack**, **repack_offline**, **uncompress**, and **uncompress_offline** arguments after a prior interrupted command.

You cannot perform a compress, repack, repack_offline, shrink, uncompress, or uncompress_offline operation on a table or fragment while any of these operations is already occurring on the table or fragment.

When you specify multiple operations in a single command, the server performs the operations in this order:

- **create_dictionary**
- **compress**
- **repack**
- **shrink**

Compress, repack, repack_offline, uncompress, and uncompress_offline operations can consume large amounts of log files. Configure your logs to be larger if any workload that you expect to run, including but not limited to these compression operations, consumes log files faster than one every 30 seconds.

Compress, repack, and uncompress operations are logged, but run in small portions.

If you change the fragmentation strategy for a table after you perform a compression operation, the table loses its compression status and will need to be recompressed.

Dropping or disabling indexes before you complete a repack_offline or uncompress_offline operation can decrease the amount of time that it takes the server to complete the operation. Afterward, you can re-create or re-enable the indexes, preferably taking advantage of PDQ. Dropping or disabling the indexes and then creating or enabling them again can be faster than completing a repack_offline or uncompress_offline operation without doing this.

Do not drop a dbspace that Change Data Capture (CDC) API is using, if the dbspace ever contained compressed tables, because this might delete compression dictionaries that CDC still needs.

Repack

The compress operation normally creates a quantity of free space on individual data and remainder pages, but the space is not consolidated at the end of the table or fragment. Instead, the space can be used to hold newly inserted rows, with the table not growing any larger until this space is filled.

A compress operation, which only occurs online, compresses rows of a table in-place. The repack operation moves the rows. You can perform a repack operation online or offline. An online operation allows concurrent activity to occur on a table. However, this can result in *phantom rows*. (Phantom rows are rows that are initially modified or inserted during a transaction that is later rolled back.)

To avoid phantom rows, you might want to repack offline, when you can afford to keep other users from accessing a table or fragment. For example, you could perform a compress operation with concurrent activity during the day, and then perform a repack_offline operation at night, when no concurrent activity is expected on the table.

You cannot perform an offline operation with an online operation. For example, while you can perform a combined compress repack operation, you cannot perform a combined compress repack_offline operation. If you want to repack offline, you must do this in two steps:

1. Perform a compress operation.
2. Perform a repack_offline operation.

Similarly you cannot perform a repack_offline shrink operation.

If light appends (unbuffered, unlogged insert operations) occur in a table or fragment while a repack operation is occurring, the repack operation does not complete the consolidation of space at the end of a table or fragment. The repack operation does not complete because the new extents are added in the location where the repack operation already occurred, so space cannot be returned to the dbspace. To complete the repack process, you must run a second repack operation after light append activity completes. This second repack operation builds on the work of the first repack operation.

Shrink

The shrink operation is typically performed after a repack operation.

You can safely shrink the entire table without compromising the allocation strategy of the table. For example, if you have a fragmented table with one fragment for each day of the week and many fragments pre-allocated for future use, you can shrink the table without compromising this allocation strategy. If the table is empty, Informix shrinks the table to the initial extent size that was specified when the table was created.

When you initiate a shrink operation, Informix shortens extents as follows:

- It shortens all extents except the first extent to as small a size as possible.
- If the table is entirely in the first extent (for example, because the table is an empty table), Informix does not shrink the first extent to a size that was smaller than the extent size that was specified when the table was created with the CREATE TABLE statement.

You can use the MODIFY EXTENT SIZE clause of the ALTER TABLE statement to reduce the current extent size. After you do this, you can rerun the shrink operation to shrink the first extent to the new extent size.

Uncompress

The uncompress operation has no effect on any table or fragment it is applied to that is not compressed.

After you uncompress a table or fragment, you can perform a purge_dictionary operation to delete the dictionary for that table or fragment.

Purge

Before you perform a purge_dictionary operation for tables and fragments, you must:

- Uncompress the tables and fragments.
  When you uncompress a table or fragment, Informix marks the dictionary for the table or fragment as inactive.
- Be sure that Enterprise Replication functions do not need the compression dictionaries for older logs.
- Archive any dbspace that contains a table or fragment with a compression dictionary, even if you have uncompressed data in the table or fragment and the dictionary is no longer active.

You can also delete all compression dictionaries or all compression dictionaries that were created before and on a specified date. For information, see purge compression dictionary arguments: Remove compression dictionaries (SQL administration API).

Examples

The following command compresses, repacks, and shrinks both row data in a table that is named **auto** in the **insurance** database of which **tjones** is the owner and simple large objects in the dbspace.

```
EXECUTE FUNCTION task("table compress repack shrink","auto",
"insurance","tjones");
```

The following command compresses only row data in a table named **dental** in parallel.

```
EXECUTE FUNCTION task("table compress rows parallel","dental");
```

The following command uncompresses the fragment with the partition number 14680071.

```
EXECUTE FUNCTION task("fragment uncompress","14680071");
```

The following command uncompresses only row data in the fragment with the partition number 14680071 in parallel.

```
EXECUTE FUNCTION task("fragment uncompress rows parallel","14680071");
```

The following command estimates the benefit of compressing a table that is named **home** in the **insurance** database of which **fgomez** is the owner.

```
EXECUTE FUNCTION task("table estimate_compression","home",
"insurance","fgomez");
```

The following command removes pending in-place alter operations on a table that is named **auto** in parallel.

```
EXECUTE FUNCTION task("table update_ipa parallel","auto");
```

After you run the command, the database server displays an estimate of the compression ratio that can be achieved, along with the currently achieved compression ratio (if it exists). For information about the output of the command, see Output of the estimate compression operation (SQL administration API).

Related reference:
Output of the estimate compression operation (SQL administration API)
onstat -g ath command: Print information about all threads
Related information:
Compression

Output of the estimate compression operation (SQL administration API)

After you run the command for estimating compression ratios, the database server displays information that shows the estimate of the compression ratio that can be achieved, along with the currently achieved compression ratio (if it exists).

Table 1. Information that an estimate_compression command displays

Column	Information Displayed
`est`	This is the estimate of the compression ratio that can be achieved with a new compression dictionary. The estimate is a percentage of space saved compared to no compression.
`curr`	This is the estimate of the currently achieved compression ratio. This estimate is a percentage of space saved compared to no compression. `0.0%` will always appear for non-compressed fragments or tables.
`change`	This is the estimate of the percentage point gain (or possibly loss, although that should be rare) in the compression ratio that you could achieve by switching to a new compression dictionary. This is just the difference between `est` and `curr`. If the table or fragment is not compressed, you can create a compression dictionary with the compress parameter. If the fragment is compressed, you must perform an uncompress or uncompress_offline operation, before you can compress.
`partnum`	This is the partition number of the fragment.
`coloff`	This value defines whether the estimate is for in-row data or simple large objects in the dbspace, as follows: • -1 indicates that the estimate for in-row data • A positive numeric value indicates that the estimate is for a partition simple large object at the offset identified by the value. The offset is the column offset in the table in bytes.
`table`	This is the full name of the table to which the fragment belongs, in format *`database:owner.tablename`* If you are estimating compression benefits for an index, the full name of the index appears in this column.

Example

The following output shows that a .4 percent increase in saved space can occur if you recompress the first fragment. A 75.7 percent increase can occur if you compress the second fragment, which is not compressed. The value -1 in the `coloff` column indicates that in-row data is compressed.

```
est   curr  change  partnum    coloff  table
----- ----- ------ -------------  ------------------------------
75.7% 75.3%   +0.4  0x00200003     -1  insurance:bwilson.auto
75.7%  0.0%  +75.7  0x00300002     -1  insurance:pchang.home
```

The following output shows compression estimates for in-row data (in the first row) and simple large objects at offsets 4 and 60 (in the second and third rows):

```
est   curr  change  partnum    coloff  table
----- ----- ------ -------------  --------------------
75.4% 71.5%  +3.9 0x00200002       -1 test:mah.table1
 5.0% 75.0%  +0.0 0x00200002        4 test:mah.table1
75.0% 75.0%  +0.0 0x00200002       60 test:mah.table1
```

Output from compression estimates for tables and fragments look the same, except that the output for a table always shows all fragments in the table, while the output for a fragment only shows information for the specified fragments.

Related reference:
index estimate_compression argument: Estimate index compression (SQL administration API)
table or fragment arguments: Compress data and optimize storage (SQL administration API)

purge compression dictionary arguments: Remove compression dictionaries (SQL administration API)

Call the **admin()** or **task()** function with the compression purge_dictionary initial command to delete all inactive compression dictionaries or all inactive compression dictionaries that were created for a compressed table or fragment before a specified date. You must uncompress tables and fragments, which makes the dictionaries inactive, before you delete any compression dictionaries that were created for the tables and fragments.

Syntax: Compression Purge_Dictionary

```
>>-EXECUTE FUNCTION--+-admin-+--(--"--compression purge_dictionary--"--,--"--date--"--)-- ;-><
                     '-task--'
```

Usage

Before you perform a purge_dictionary operation for tables and fragments, you must:

- Uncompress the tables and fragments.
  When you uncompress a table or fragment, Informix® marks the dictionary for the table or fragment as inactive.
- Be sure that Enterprise Replication functions do not need the compression dictionaries.
- Archive any dbspace that contains a table or fragment with a compression dictionary, even if you have uncompressed data in the table or fragment and the dictionary is no longer active.

The compression purge_dictionary command deletes all compression dictionaries.

The compression purge_dictionary command with a date as the second argument deletes all compression dictionaries that were created before and on a specified date. You can use any date in a format that can be converted to a DATE data type based on your locale and environment. For example, you can specify `03/29/2009`, `03/29/09`, or `Mar 29, 2009`.

You can also delete a specific compression dictionary by calling the **admin()** or **task()** function with table or fragment as the initial command and purge_dictionary as the next argument.

You cannot delete compression dictionaries that were created for indexes. The database server removes these compression dictionaries when the indexes are dropped.

The following command tells Informix to remove all dictionaries that were created before and on July 8, 2009:

```
EXECUTE FUNCTION task("compression purge_dictionary", "07/08/2009");
```

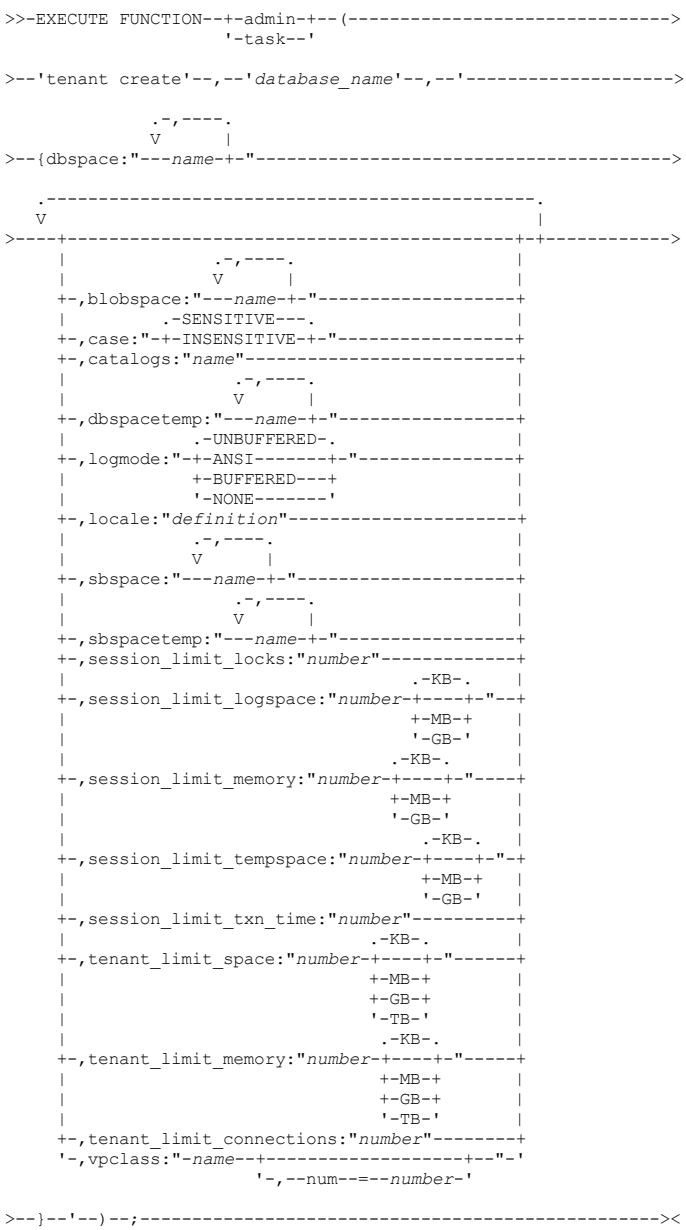
The following command tells Informix to remove the inactive dictionary for a table named **auto** in the **insurance** database of which **tjones** is the owner.

```
EXECUTE FUNCTION task("table purge_dictionary",
"auto", "insurance", "tjones");
```

tenant create argument: Create a tenant database (SQL Administration API)

Use the **tenant create** argument with the **admin()** or **task()** function to create a tenant database.

Syntax



Element	Description	Key Considerations
blobspace	A comma-separated list of one or more blobspaces that are assigned to the tenant database.	At least one blobspace is required if the tenant database contains simple large objects. blobspaces must be empty to be assigned to a tenant database. blobspaces must exist before being assigned to a tenant database. Simple large objects that are created outside of a tenant database cannot be stored in the tenant database's blobspaces.
case	Database sensitivity to uppercase and lowercase letters: INSENSITIVE Case insensitive. SENSITIVE Case sensitive. This is the default value.	If you omit this property, the database is case sensitive.
catalogs	A dbspace to store the tenant database catalogs.	The dbspace must be listed in the **dbspace** property. If you omit this property, the dbspace that is listed as the first value of the **dbspace** property contains the tenant database catalogs.

Element	Description	Key Considerations
database_name	The name of the tenant database.	The database name must be on the database server. An existing non-tenant database cannot become a tenant database.
dbspace	A comma-separated list of one or more dbspaces that are assigned to the tenant database.	dbspaces must be empty to be assigned to a tenant database. dbspaces must exist before being assigned to a tenant database. Objects that are created outside of a tenant database cannot be stored in the tenant database's dbspaces.
dbspacetemp	A comma-separated list of one or more temporary dbspaces that are assigned to a tenant database.	You can override the **dbspacetemp** property for a session by setting the DBSPACETEMP environment variable to a subset of the dbspaces that are specified by the **dbspacetemp** property. If the **dbspacetemp** property is omitted, temporary tables are stored in the temporary dbspaces that are specified by the DBSPACETEMP configuration parameter or environment variable.
locale	The locale of the database.	The values for **locale** are the same as the values for the DB_LOCALE environment variable. The default locale is en_US.819.
logmode	The log mode definition: UNBUFFERED Unbuffered database logging. This is the default. ANSI ANSI-compliant database logging. BUFFERED Buffered database logging. NONE No database logging.	If you omit this property, the logging mode is unbuffered.
sbspace	A comma-separated list of one or more sbspaces that are assigned to the tenant database.	At least one sbspace is required if the tenant database contains smart large objects. Smart large objects can include BLOB or CLOB data, and data and table statistics that are too large to fit in a row. sbspaces must be empty to be assigned to a tenant database. sbspaces must exist before being assigned to a tenant database. Smart large objects that are created outside of a tenant database cannot be stored in the tenant database's sbspaces. Some features, such as Enterprise Replication, spatial data, and basic text searching, require sbspaces.
num	The number of virtual processors to run.	If you do not include the **num** property, 1 virtual processor is started.
sbspacetemp	A comma-separated list of one or more temporary sbspaces that are assigned to the tenant database.	If you omit this property, temporary smart large objects are stored in the temporary sbspaces that are specified by the SBSPACETEMP configuration parameter.
session_limit_locks	The maximum number of locks available to a session.	The value must be 500 - 2147483648. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_locks** property takes precedent over the value of the SESSION_LIMIT_LOCKS configuration parameter. If you omit this property, the number of locks are set by the SESSION_LIMIT_LOCKS configuration parameter. If the SESSION_LIMIT_LOCKS configuration parameter is also not set, the maximum number of locks for a session is 2147483648. You can override the **session_limit_locks** property for a session by setting the IFX_SESSION_LIMIT_LOCKS environment option to a lower value than the **session_limit_locks** property value.
session_limit_logspace	The maximum amount of log space that a session can use for individual transactions.	The value must be 5120 - 2147483648 KB. Values are specified in KB, MB, or GB. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_logspace** property takes precedent over the value of the SESSION_LIMIT_LOGSPACE configuration parameter. If you omit this property, the amount of logspace is set by the SESSION_LIMIT_LOGSPACE configuration parameter. If the SESSION_LIMIT_LOGSPACE configuration parameter is also not set, the maximum amount of log space that a session can use for individual transactions is 2147483648 KB.

Element	Description	Key Considerations
session_limit_memory	The maximum amount of memory that a session can allocate.	The value must be 20480 - 2147483648 KB. Values are specified in KB, MB, or GB. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_memory** property takes precedent over the value of the SESSION_LIMIT_MEMORY configuration parameter. If you omit this property, the amount of memory is set by the SESSION_LIMIT_MEMORY configuration parameter. If the SESSION_LIMIT_MEMORY configuration parameter is also not set, the maximum amount of memory that a session can allocate is 2147483648 KB.
session_limit_tempspace	The maximum amount of temporary table space that a session can allocate.	The value must be 20480 - 2147483648 KB. Values are specified in KB, MB, or GB. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_tempspace** property takes precedent over the value of the SESSION_LIMIT_TEMPSPACE configuration parameter. If you omit this property, the amount of temporary table space is set by the SESSION_LIMIT_TEMPSPACE configuration parameter. If the SESSION_LIMIT_TEMPSPACE configuration parameter is also not set, the maximum amount of temporary table space that a session can allocate is 2147483648 KB.
session_limit_txn_time	The maximum amount of time that a transaction can run in a session.	The value must be 60 - 20000000000. Values are in seconds. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_txn_time** property takes precedent over the value of the SESSION_LIMIT_TXN_TIME configuration parameter. If you omit this property, the amount of time is set by the SESSION_LIMIT_TXN_TIME configuration parameter. If the SESSION_LIMIT_TXN_TIME configuration parameter is also not set, the maximum amount of time that a transaction can run in a session is 20000000000 seconds.
tenant_limit_space	The maximum amount of storage space on disk to a tenant database. When the limit is reached, subsequent operations that require more disk space are rejected.	The value must be 1048576 - 1717986918400 KB (1 GB - 200 TB). Values are specified in KB, MB, GB, or TB. The value of the **tenant_limit_space** property takes precedent over the value of the TENANT_LIMIT_SPACE configuration parameter. If you omit this property, the amount of space is set by the TENANT_LIMIT_SPACE configuration parameter. If the TENANT_LIMIT_SPACE configuration parameter is also not set, the maximum amount of storage space available to a tenant user is 1717986918400 KB.
tenant_limit_memory	The maximum amount of shared memory for all sessions that are connected to the tenant database. When the limit is exceeded, the session that is using the most shared memory is terminated.	The value must be 102400 - 2147483648 KB (100 MB - 2 TB). Values are specified in KB, MB, GB, or TB. The value of the **tenant_limit_memory** property takes precedent over the value of the TENANT_LIMIT_MEMORY configuration parameter. If you omit this property, the amount of memory is set by the TENANT_LIMIT_MEMORY configuration parameter. If the TENANT_LIMIT_MEMORY configuration parameter is also not set, the maximum amount of memory available to a tenant session is 2147483648 KB.
tenant_limit_connections	The maximum number of connections to a tenant database. When the limit is reached, subsequent connection requests are rejected.	The value must be 1 - 65536. The value of the **tenant_limit_connections** property takes precedent over the value of the TENANT_LIMIT_CONNECTIONS configuration parameter. If you omit this property, the number of connections is set by the TENANT_LIMIT_CONNECTIONS configuration parameter. If the TENANT_LIMIT_CONNECTIONS configuration parameter is also not set, the maximum number of connections for a tenant database is 65536.
vpclass	The name of the virtual processor class for running tenant-database session threads.	If you omit this property, session threads are run on CPU virtual processors. Values must be 8 characters or fewer. A maximum of 200 tenant virtual processor classes can be created. If the virtual processor class name is unique, you create a new tenant virtual processor class. If the virtual processor class name exists, the tenant database shares the class with other tenant databases. When a tenant virtual processor is dropped, the virtual processor class ID resources are not freed until the database server is restarted.

Usage

You must have DBA privileges or been granted the TENANT privilege to run this command. Only the first occurrence of each property is valid.

Run the **tenant create** argument with the **admin()** or **task()** to create a tenant database. The user that creates the database is granted DBA privileges. You can view the tenant database properties in the **sysadmin** database's **tenant** table.

The following statement creates a tenant database that is named **company_A**:

```
EXECUTE FUNCTION task('tenant create', 'company_A',
   '{dbspace:"company_A_dbs1,company_A_dbs2,company_A_dbs3",
     sbspace:"company_A_sbs",
     vpclass:"tvp_A,num=6",
     dbspacetemp:"company_A_tdbs",
```

```
     session_limit_locks:"1000",
     session_limit_memory:"100MB",
     session_limit_tempspace:"25MB",
     session_limit_logspace:"30MB",
     session_limit_txn_time:"120",
     tenant_limit_space:"2TB",
     tenant_limit_memory:"1GB",
     tenant_limit_connections:"1000",
     logmode:"ansi",
     locale:"fr_ca.8859-1",
     case:"insensitive",}'
);
```

The tenant database has the following attributes:

- Three dedicated dbspaces
- A dedicated sbspace
- Six tenant virtual processors
- A dedicated temporary dbspace
- A limit of 1000 locks per session
- A memory allocation limit of 100 MB per session
- A 25 MB limit for temporary table space per session
- A 30 MB limit for log space per session
- A 120 second limit on transaction times
- A limit of 2 TB on the total amount of storage space the tenant database can use
- A limit of 1 GB on the total amount of shared memory for all sessions that are connected to the tenant database
- A limit of 1000 connections
- ANSI logging mode
- French locale
- Case insensitivity
- Temporary smart large objects are stored in the sbspace that is specified by the database server's SBSPACETEMP configuration parameter.
- No blobspaces

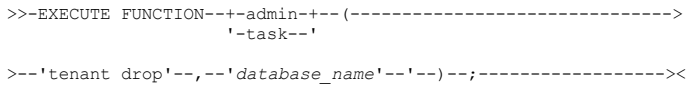
DB_LOCALE environment variable

tenant drop argument: Drop a tenant database (SQL Administration API)

Use the tenant drop argument with the **admin()** or **task()** function to drop a tenant database.

Syntax



Element	Description	Key Considerations
database_name	The name of the tenant database.	Must be an existing tenant database.

Usage

You must have DBA privileges or been granted the TENANT privilege to run this command. No other connections to the database can be open.

The tables and data in the database are deleted. The storage spaces that are dedicated to the tenant database are freed. The database tenant properties are removed from the **tenant** table in the **sysadmin** database. The associated tenant virtual processor class is dropped if it is not associated with any other tenant database.

The following statement drops the **companyA** tenant database:

```
EXECUTE FUNCTION task('tenant drop', 'companyA');
```

tenant update argument: Modify tenant database properties (SQL Administration API)

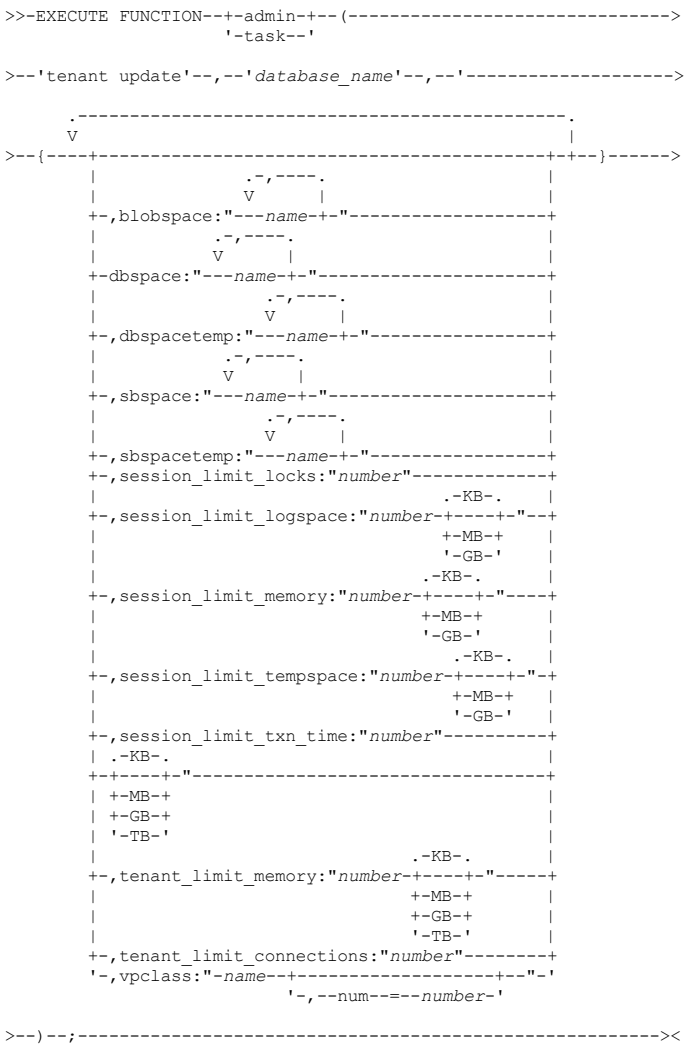
Use the tenant update argument with the **admin()** or **task()** function to modify the properties of a tenant database.

Syntax



Element	Description	Key Considerations
blobspace	A comma-separated list of one or more blobspaces that are assigned to the tenant database.	Specified blobspaces are appended to the tenant database's existing list of blobspaces. blobspaces must be empty to be assigned to a tenant database. blobspaces must exist before being assigned to a tenant database.
database_name	The name of the tenant database.	The database name must be on the database server.
dbspace	A comma-separated list of one or more dbspaces that are assigned to the tenant database.	Specified dbspaces are appended to the tenant database's existing list of dbspaces. dbspaces must be empty to be assigned to a tenant database. dbspaces must exist before being assigned to a tenant database.

Element	Description	Key Considerations
dbspacetemp	A comma-separated list of one or more temporary dbspaces that are assigned to a tenant database.	The existing **dbspacetemp** property value is replaced. You can override the **dbspacetemp** property for a session by setting the DBSPACETEMP environment variable to a subset of the dbspaces that are specified by the **dbspacetemp** property. If the **dbspacetemp** property is omitted, temporary tables are stored in the temporary dbspaces that are specified by the DBSPACETEMP configuration parameter or environment variable.
sbspace	A comma-separated list of one or more sbspaces that are assigned to the tenant database.	Specified sbspaces are appended to the tenant database's existing list of sbspaces. sbspaces must be empty to be assigned to a tenant database. sbspaces must exist before being assigned to a tenant database.
num	The number of virtual processors to run.	If you do not include the **num** property, 1 virtual processor is started.
sbspacetemp	A comma-separated list of one or more temporary sbspaces that are assigned to the tenant database.	The existing **sbspacetemp** property value is replaced.
session_limit_locks	The maximum number of locks for a session for users who do not have DBA privileges.	The existing **session_limit_locks** property value is replaced. The value must be 500 - 2147483648. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. If this property is not set, the number of locks are set by the SESSION_LIMIT_LOCKS configuration parameter. If the SESSION_LIMIT_LOCKS configuration parameter is also not set, the maximum number of locks for a session is 2147483648. You can override the **session_limit_locks** property for a session by setting the IFX_SESSION_LIMIT_LOCKS environment option to a lower value than the **session_limit_locks** property value.
session_limit_logspace	The maximum amount of log space that a session can use for individual transactions.	The existing **session_limit_logspace** property value is replaced. The value must be 5120 - 2147483648 KB. Values are specified in KB, MB, or GB. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_logspace** property takes precedent over the value of the SESSION_LIMIT_LOGSPACE configuration parameter. If you omit this property, the amount of logspace is set by the SESSION_LIMIT_LOGSPACE configuration parameter. If the SESSION_LIMIT_LOGSPACE configuration parameter is also not set, the maximum amount of log space that a session can use for individual transactions is 2147483648 KB.
session_limit_memory	The maximum amount of memory that a session can allocate.	The existing **session_limit_memory** property value is replaced. The value must be 20480 - 2147483648 KB. Values are specified in KB, MB, or GB. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_memory** property takes precedent over the value of the SESSION_LIMIT_MEMORY configuration parameter. If this property is not set, the amount of memory is set by the SESSION_LIMIT_MEMORY configuration parameter. If the SESSION_LIMIT_MEMORY configuration parameter is also not set, the maximum amount of memory that a session can allocate is 2147483648 KB.
session_limit_tempspace	The maximum amount of temporary table space that a session can allocate.	The existing **session_limit_tempspace** property value is replaced. The value must be 20480 - 2147483648 KB. Values are specified in KB, MB, or GB. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_tempspace** property takes precedent over the value of the SESSION_LIMIT_TEMPSPACE configuration parameter. If this property is not set, the amount of temporary table space is set by the SESSION_LIMIT_TEMPSPACE configuration parameter. If the SESSION_LIMIT_TEMPSPACE configuration parameter is also not set, the maximum amount of temporary table space that a session can allocate is 2147483648 KB.

Element	Description	Key Considerations
session_limit_txn_time	The maximum amount of time that a transaction can run in a session.	The existing **session_limit_txn_time** property value is replaced. The value must be 60 - 20000000000. Values are in seconds. This limit does not apply to a user who holds administrative privileges, such as user **informix** or a DBSA user. The value of the **session_limit_txn_time** property takes precedent over the value of the SESSION_LIMIT_TXN_TIME configuration parameter. If you omit this property, the amount of time is set by the SESSION_LIMIT_TXN_TIME configuration parameter. If the SESSION_LIMIT_TXN_TIME configuration parameter is also not set, the maximum amount of time that a transaction can run in a session is 20000000000 seconds.
tenant_limit_space	The maximum amount of storage space on disk to a tenant database. When the limit is reached, subsequent operations that require more disk space are rejected.	The existing **tenant_limit_space** property value is replaced. The value must be 1048576 - 1717986918400 KB (1 GB - 200 TB). Values are specified in KB, MB, GB, or TB. The value of the **tenant_limit_space** property takes precedent over the value of the TENANT_LIMIT_SPACE configuration parameter. If you omit this property, the amount of space is set by the TENANT_LIMIT_SPACE configuration parameter. If the TENANT_LIMIT_SPACE configuration parameter is also not set, the maximum amount of storage space available to a tenant user is 1717986918400 KB.
tenant_limit_memory	The maximum amount of shared memory for all sessions that are connected to the tenant database. When the limit is exceeded, the session that is using the most shared memory is terminated.	The existing **tenant_limit_memory** property value is replaced. The value must be 102400 - 2147483648 KB (100 MB - 2 TB). Values are specified in KB, MB, GB, or TB. The value of the **tenant_limit_memory** property takes precedent over the value of the TENANT_LIMIT_MEMORY configuration parameter. If you omit this property, the amount of memory is set by the TENANT_LIMIT_MEMORY configuration parameter. If the TENANT_LIMIT_MEMORY configuration parameter is also not set, the maximum amount of memory available to a tenant session is 2147483648 KB.
tenant_limit_connections	The maximum number of connections to a tenant database. When the limit is reached, subsequent connection requests are rejected.	The existing **tenant_limit_connections** property value is replaced. The value must be 1 - 65536. The value of the **tenant_limit_connections** property takes precedent over the value of the TENANT_LIMIT_CONNECTIONS configuration parameter. If you omit this property, the number of connections is set by the TENANT_LIMIT_CONNECTIONS configuration parameter. If the TENANT_LIMIT_CONNECTIONS configuration parameter is also not set, the maximum number of connections for a tenant database is 65536.
vpclass	The name of the virtual processor class for running tenant-database session threads.	The **vpclass** property value is replaced. If you omit this property, session threads are run on CPU virtual processors. Values must be 8 characters or fewer. A maximum of 200 tenant virtual processor classes can be created. If the virtual processor class name is unique, you create a new tenant virtual processor class. If the virtual processor class name exists, the tenant database shares the class with other tenant databases. When a tenant virtual processor is dropped, the virtual processor class ID resources are not freed until the database server is restarted.

Usage

You must be user **informix** or a DBSA user, or you must have the TENANT privilege to run this command.

The changes to the database properties take effect for new sessions.

The following statement updates the properties of the tenant database that is named **company_A**:

```
EXECUTE FUNCTION task('tenant update', 'company_A',
                      '{dbspace:"company_A_dbs4,company_A_dbs5",
                        sbspace:"company_A_sbs3",
                        vpclass:"tvp_B",
                        session_limit_txn_time:"120"}'
);
```

The tenant database gains two dbspaces and an sbspace, the virtual processor class is changed, and the time limit on transactions becomes 120 seconds.

Appendixes

- Database server files
  Database server files are created in default directories, or in a directory that the relevant configuration parameter specifies. A database administrator might need to edit or examine the content of files that are used by the database server.
- Troubleshooting errors
  Occasionally, a series of events causes the database server to return unexpected error codes.
- Event Alarms
  The database server provides a mechanism for automatically triggering administrative actions based on an event that occurs in the database server environment. This mechanism is the event-alarm feature.
- Messages in the database server log
  Unnumbered messages are printed in the database server message log (online.log). The error messages include corrective actions.
- Limits in Informix
  This topic lists the system-level and table-level parameter limits, the system defaults, and the access capabilities of Informix.

Database server files

Database server files are created in default directories, or in a directory that the relevant configuration parameter specifies. A database administrator might need to edit or examine the content of files that are used by the database server.

- Table 1 lists database server files that you might need to look at, copy, edit, move, or delete (except where noted).
- Table 2 lists database server files that are for internal use only. You must not edit, move, or delete these files.

Table 1. Database server files that you can use. This table lists the files that you might refer to or use when you configure and use the database server.

File name	Directory	Purpose	Created
af.*xxx* *xxx* identifies a specific assertion failure	$INFORMIXDIR/tmp (UNIX) %INFORMIXDIR%\tmp (Windows) Specified by DUMPDIR configuration parameter	Assertion-failure information	By the database server
ac_msg.log	/tmp (UNIX) %INFORMIXDIR%\etc (Windows)	The message log for the **archecker** utility	By the database server
ac_config.std	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	Template for **archecker**parameter values	By the database server
bar_act.log	/tmp (UNIX) %INFORMIXDIR%\etc (Windows) Specified by the BAR_ACT_LOG configuration parameter	ON-Bar activity log	By ON-Bar
bar_dbug.log	/usr/informix/ (UNIX) \usr\informix\ (Windows) Specified by the BAR_DEBUG_LOG configuration parameter	ON-Bar debug log	By ON-Bar
bldutil.*process_id* (UNIX) bldutil.out (Windows)	/tmp (UNIX) \tmp (Windows)	Error messages about building the **sysutils** database	By the database server
buildsmi.out (UNIX) buildsmi_out.*%INFORMIXSERVER%* (Windows)	/tmp (UNIX) %INFORMIXDIR%\etc (Windows)	Error messages about building the **sysmaster** database	By the database server
concdr.sh	$INFORMIXDIR /etc/conv (UNIX) %INFORMIXDIR% \etc\conv (Windows)	Converts the **syscdr** database during an upgrade	By the database server
core (UNIX)	Directory from which the database server was started	Core dump	By the database server
gcore.*xxx* (UNIX)	$INFORMIXDIR/tmp (UNIX) %INFORMIXDIR%\tmp (Windows) Specified by DUMPDIR configuration parameter	Assertion failure information	By the database server
.informix (UNIX)	User's home directory	Set personal environment variables	By the user

File name	Directory	Purpose	Created
informix.rc (UNIX)	$INFORMIXDIR/etc	Set default environment variables for all users	By the database administrator
InstallServer.log (Windows)	C:\temp	Database server installation log	By the database server
ixbar.*servernum*	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	Emergency boot file that is used in a cold restore	By ON-Bar
jvp.log	/urs/informix Specified by JVPLOGFILE configuration parameter	Messages from the Java™ virtual processor	By the database server
.jvpprops	urs/informix/extend/krakatoa Specified by JVPPROPFILE configuration parameter	Template for Java VP properties	During installation
oncfg_ *servername.servernum*	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	Configuration information for whole-system restores by ON-Bar	By the database server
online.log	$INFORMIXDIR/tmp (UNIX) %INFORMIXDIR% (Windows) Specified by the MSGPATH configuration parameter	Database server message log, which contains error messages and status information	By the database server
onconfig	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	Configuration information	By the database administrator or the database server administrator
onconfig.std	$INFORMIXDIR/etc (UNIX)	Template for configuration parameter values Important: Do not move, modify, or delete the onconfig.std file unless instructed to do so by Software Support. However, you may make a copy of the onconfig.std file to create a customized configuration file, and then move the copy to another location.	During installation
onsnmp.*servername*	/tmp (UNIX) \tmp (Windows)	Log file that the **onsnmp** subagent uses	By the **onsnmp** utility
onsrvapd.log	/tmp (UNIX) \tmp (Windows)	Log file for the database server daemon **onsrvapd**	By the **onsnmp** utility
psm_act.log	/tmp (UNIX) %INFORMIXDIR%\etc (Windows) Specified by the PSM_ACT_LOG configuration parameter	Log file for Informix® Primary Storage Manager	By ON-Bar
pua.map	$INFORMIXDIR/gls/etc (UNIX) %INFORMIXDIR%\gls\etc\(Windows)	Mapping file for displaying characters in Unicode Private-Use Area (PUA) ranges.	By the user
revcdr.sh (UNIX) revcdr.bat (Windows)	$INFORMIXDIR/etc/conv (UNIX) %INFORMIXDIR%\etc\conv(Windows)	Reverts the **syscdr** database to an earlier format	By the database server
shmem.*xxx*	$INFORMIXDIR/tmp (UNIX) %INFORMIXDIR%\tmp (Windows) Specified by DUMPDIR configuration parameter	Assertion-failure information	By the database server
sm_versions.std	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	Identifies storage manager in use	During installation
snmpd.log	/tmp (UNIX) \tmp (Windows)	Log file for the SNMP master agent, **snmpdm**	By **onsnmp**
sqlhosts.*servername*	$INFORMIXDIR/etc %INFORMIXDIR%\etc (Windows)	Connection information	During installation; modified by the database server administrator The file extension is the server name (the default extension is ol_informix*version*)
sqlhosts.std	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	Template for connection information	During installation

Table 2. Database server files that are for internal use only. This table lists the files that are required by the database server.
Important: Do not move, modify, or delete these files unless instructed to do so by Software Support.

File name	Directory	Purpose	Created
.conf.*dbservername*	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	The **onsnmp** utility uses this file to obtain the database server configuration	By the database server
illlsrra.*xx*	$INFORMIXDIR/lib (UNIX) %INFORMIXDIR%\lib (Windows)	Shared libraries for the database server and some utilities	By installation procedure
INFORMIXTMP	/INFORMIXTMP (UNIX) \%INFORMIXDIR% (Windows)	Temporary directory for internal files	By the database server
.inf.servicename	/INFORMIXTMP (UNIX) drive:\INFORMIXTMP (Windows)	Connection information	By the database server

File name	Directory	Purpose	Created
.infos.*dbservername*	$INFORMIXDIR/etc (UNIX) %INFORMIXDIR%\etc (Windows)	Connection information	By the database server
.infxdirs	/INFORMIXTMP (UNIX) *drive*:\INFORMIXTMP (Windows)	Database server discovery file that **onsnmp** uses	By the database server
JVM_*vpid*	Specified by JVPLOG configuration parameter	Messages that the Java virtual machine generates	By the Java virtual machine
servicename.exp	/INFORMIXTMP (UNIX) *drive*:\INFORMIXTMP (Windows)	Connection information	By the database server
servicename.str	/INFORMIXTMP (UNIX) *drive*:\INFORMIXTMP (Windows)	Connection information	By the database server
VP.*servername.nnx*	/INFORMIXTMP (UNIX) *drive*:\INFORMIXTMP (Windows)	Connection information	By the database server

Troubleshooting errors

Occasionally, a series of events causes the database server to return unexpected error codes.

You can use the following diagnostic tools to gather information for troubleshooting errors:

- **onmode -I**
- tracepoints
- The **ifxcollect** tool

- Collecting Diagnostics using onmode -I
- Creating Tracepoints
- Collecting data with the ifxcollect tool
  You can use the **ifxcollect** tool to collect diagnostic data if necessary for troubleshooting a specific problem, such as an assertion failure. You can also specify options for transmitting the collected data via the File Transfer Protocol (FTP). .

Collecting Diagnostics using onmode -I

To help collect additional diagnostics, you can use **onmode -I** to instruct the database server to perform the diagnostics collection procedures that the *IBM® Informix® Administrator's Guide* describes. To use **onmode -I** when you encounter an error number, supply the *iserrno* and an optional session ID. For more information about **onmode**, see The onmode utility.

Related reference:
Creating Tracepoints
Collecting data with the ifxcollect tool

Creating Tracepoints

Tracepoints are useful in debugging user-defined routines written in C. You can create a user-defined tracepoint to send special information about the current execution state of a user-defined routine.

Each tracepoint has the following parts:

- A *trace* groups related tracepoints together so that they can be turned on or off at the same time.
  You can either use the built-in trace called **_myErrors** or create your own. To create your own trace, you insert rows into the **systracees** system catalog table.
- A *trace message* is the text that the database server sends to the tracing-output file.
  You can store internationalized trace messages in the **systracemsgs** system catalog table.
- A *tracepoint threshold* determines when the tracepoint executes.

By default, the database server puts all trace messages in the trace-output file in the **tmp** directory with the following filename:

session_num.trc

For more information on tracing user-defined routines, see the *IBM® Informix® DataBlade API Programmer's Guide*.

Related concepts:
Collecting Diagnostics using onmode -I
Related reference:
Collecting data with the ifxcollect tool

Collecting data with the ifxcollect tool

You can use the **ifxcollect** tool to collect diagnostic data if necessary for troubleshooting a specific problem, such as an assertion failure. You can also specify options for transmitting the collected data via the File Transfer Protocol (FTP). .

The **ifxcollect** tool is in the **$INFORMIXDIR/bin** directory. Output files that **ifxcollect** commands generate are in the **$INFORMIXDIR/isa/data** directory.

The type of data that is collected per category and subcategory is in predefined XML files in the **$INFORMIXDIR/isa/** directory. These XML files can be modified to add or remove specific commands.

Important: The XML files can contain commands that override the options that are specified for data collection. For example, an XML file might contain sleep commands that override the **-d** option with a shorter number of seconds; or an XML file might contain a call to **onstat -z**.

Syntax

```
>>-ifxcollect-- -c - category -- -s - subcategory --------------->

>--+-------------------------+--+-----------------+--+-----+------>
   '- -r - number_of_times -'  '- -d - seconds -'  '- -y '

>--+-----------+--+-----+-------------------------------------><
   +- -V-------+  +- -f-+
   '- -version-'  +- -e-+
                  +- -p-+
                  +- -m-+
                  +- -l-+
                  +- -u-+
                  '- -w-'
```

Table 1. Options for data collection

Element	Description	Key Considerations
-c *category*	Tells the server to collect data in the specified category.	You must specify the category of data to collect.
-s *category*	Tells the server to collect data in the specified subcategory.	You must specify the subcategory of data to collect.
-r *number of times*	Specifies the number of times to repeat data collection.	Optional. The default value is 1.
-d *number of seconds*	Specifies the number of times to pause between collection operations.	Optional. The default value is 0.
-y	Causes the database server to automatically respond yes to all prompts.	Optional.
-V	Displays the software version number and the serial number.	Optional. See Obtaining utility version information
-version	Displays the build version, host, operating system, number and date, and the GLS version.	Optional. See Obtaining utility version information

Table 2. FTP options if you also transmitting data

Element	Description	Key Considerations
-f	FTP the entire collection	Required for the transmission of data.
-e *email address*	Email address	Required for the transmission of data.
-p *the PMR number*	PMR number	Required for the transmission of data.
-m *machine name*	Machine to connect to	Required for the transmission of data.
-l *directory*	Directory that contains the data	Required for the transmission of data.
-u *user name*	User name for the FTP	Required for the transmission of data.

Element	Description	Key Considerations
-w *password*	Password for the FTP	Required for the transmission of data.

Usage

The following table shows the combination of categories and subcategories that you can use in your commands.

Table 3. Category and subcategory combinations

Category and subcategory	Explanation
`-c ids -s general`	Collects general data for issues that are related to all Informix products
`-c af -s general`	Collects general data for assertion failures
`-c er -s general`	Collects general data for Enterprise Replication
`-c er -s init`	Collects general data for Enterprise Replication initialization issues
`-c performance -s general`	Collects data for performance issues
`-c performance -s cpu`	Collects data for CPU utilization issues
`-c onbar -s archive_failure`	Collects data for **onbar** archive failures
`-c onbar -s restore_failure`	Collects data for **onbar** restore failures
`-c ontape -s archive_failure`	Collects data for **ontape** archive failures
`-c ontape -s restore_failure`	Collects data for **ontape** restore failures
`-c connection -s failure`	Collects data for connection failures
`-c connection -s hang`	Collects data for connection hangs
`-c cust -s prof`	Collects customer profile information

To view all **ifxcollect** utility command options, type `ifxcollect` at the command prompt.

Examples

To collect information for a general assertion failure, run this command:

```
ifxcollect -c af -s general
```

To collect information for a performance problem that is related to CPU utilization, run this command:

```
ifxcollect -c performance -s cpu
```

To include FTP information, specify the additional information as shown in this example:

```
-f -e user_name@company_name.org -p 9999.999.999
-f -m machine -l /tmp -u user_name -w password
```

Event Alarms

The database server provides a mechanism for automatically triggering administrative actions based on an event that occurs in the database server environment. This mechanism is the event-alarm feature.

Events can be informative (for example, `Backup Complete`) or can indicate an error condition that requires your attention (for example, `Unable to Allocate Memory`).

- Using ALARMPROGRAM to Capture Events
- Events in the ph_alert Table
  All event alarms that are generated are inserted in the **ph_alert** table in the **sysadmin** database.
- Event Alarm Parameters
  Event alarms have five parameters that describe each event.
- Event alarm IDs
  The class ID for event alarms indicates the type of event. The event ID indicates the specific event.
- Connection Manager event alarm IDs
  The class ID for event alarms indicates the type of event. The event ID indicates the specific event.

Related reference:
ALARMPROGRAM configuration parameter
ALRM_ALL_EVENTS configuration parameter

Using ALARMPROGRAM to Capture Events

On UNIX, use the **alarmprogram.sh** and on Windows, use the **alarmprogram.bat** shell script, for handling event alarms and starting automatic log backups. For the setup instructions, see ALARMPROGRAM configuration parameter.

To automate logical-log backups only, two ready-made scripts are provided: **log_full.**[**sh**|**bat**] and **no_log.**[**sh**|**bat**]. Set ALARMPROGRAM to the full path name of the script. For information, see ALARMPROGRAM configuration parameter.

- Setting ALRM_ALL_EVENTS
- Writing Your Own Alarm Script
- Customizing the ALARMPROGRAM Scripts
  You can customize the ALARMPROGRAM scripts based on your environment.
- Precautions for Foreground Operations in Alarm Scripts
  To ensure continuous server availability, do not run certain foreground operations in an alarm script.
- Interpreting event alarm messages
  Some of the events that the database server reports to the message log trigger the alarm program. The class messages indicate the events that the database server reports.

Setting ALRM_ALL_EVENTS

You can set ALRM_ALL_EVENTS to specify whether ALARMPROGRAM runs for all events that are logged in the MSGPATH or only specified noteworthy events (events greater than severity 1).

Writing Your Own Alarm Script

Alternatively, you can write your own shell script, batch file, or binary program that contains the event-alarm parameters. When an event occurs, the database server invokes this executable file and passes it the event-alarm parameters (see Table 1). For example, your script can use the **_id** and **_msg** parameters to take administrative action when a table failure occurs. Set ALARMPROGRAM to the full pathname of this executable file.

Related reference:
ALARMPROGRAM configuration parameter

Customizing the ALARMPROGRAM Scripts

You can customize the ALARMPROGRAM scripts based on your environment.

The mail utility must already be present.

Follow these steps to customize the **alarmprogram.[sh|bat]** script. You can use **alarmprogram.[sh|bat]** instead of **log_full.[sh|bat]** to automate log backups.

To customize the ALARMPROGRAM scripts:

1. Change the value of ADMINMAIL to the email address of the database server administrator.
2. Change the value of PAGERMAIL to the pager service email address.
3. Set the value of the parameter MAILUTILITY.
   - UNIX: **/usr/bin/mail**
   - Windows: **$INFORMIXDIR/bin/ntmail.exe**
   - Linux: **/usr/lib/sendmail -t**
4. To automatically back up logical logs as they fill, change BACKUP to `yes`. To stop automatic log backups, change BACKUP to any value other than `yes`.
5. In the ONCONFIG file, set ALARMPROGRAM to the full pathname of **alarmprogram.[sh|bat].**
6. Restart the database server.

Alarms with a severity of 1 or 2 do not write any messages to the message log nor send email. Alarms with severity of 3 or greater send email to the database administrator. Alarms with severity of 4 and 5 also notify a pager via email.

ALARMPROGRAM configuration parameter

Precautions for Foreground Operations in Alarm Scripts

To ensure continuous server availability, do not run certain foreground operations in an alarm script.

When the server invokes an alarm script, the server sometimes waits for the script to complete before proceeding. For example:

- When an alarm is invoked because of a fatal error, the server waits for the script to finish writing information to the error log. In certain situations, alarm events 5 and 6 are run in the foreground.
- Some Enterprise Replication event alarms run in the foreground, such as event alarms 31, 34, 37, and 39.

Because the server might need to wait for the alarm program script to finish, do not run the following operations in the foreground in an alarm script:

- An onmode command that forces user connections off the server such as `onmode -u` or `onmode -yuk`. These kinds of onmode commands can cause a deadlock between the server and the alarm script because the server might wait for the alarm script to complete while the alarm script that executed the onmode command waits for the user sessions to shut down, and one of those sessions is running the alarm script itself.
- Operations that might take a long time to complete or that have a highly variable run time. Operations that take a long time to complete can cause the server to appear as if it is not responding while the operation is running.

If you need to run the above operations in an alarm script, run them in the background using one of the following operating system utilities:

On UNIX: Use the nohup utility. For example, `nohup onmode -yuk &` instructs nohup to continue running the command even if its parent terminates and the ampersand, *&*, runs the command in the background so it will not block execution of the alarm program script itself.

On Windows: Use the start utility with the /B flag. For example, `start /B onmode -yuk`.

Interpreting event alarm messages

Some of the events that the database server reports to the message log trigger the alarm program. The class messages indicate the events that the database server reports.

The database server reports a nonzero exit code in the message log. In the alarm program, set the EXIT_STATUS variable to `0` for successful completion and to another number for a failure.

For example, if a thread attempts to acquire a lock, but the maximum number of locks are already in use, the database server writes the following message to the message log:

```
10:37:22  Checkpoint Completed:  duration was 0 seconds.
10:51:08  Lock table overflow - user id 30032, rstcb 10132264
10:51:10  Lock table overflow - user id 30032, rstcb 10132264
10:51:12  Checkpoint Completed:  duration was 1 seconds.
```

When the database server runs the **alarmprogram.sh** or **alarmprogram.bat** program, or your alarm program, the database server generates a message that describes the severity and class of the event. If the severity is greater than 2, the message takes the following format:

Action	Message
A reasonably severe server event	**Severity: 3** **Class ID: 21** **Class msg: Database server resource overflow: 'Locks'.** **Specific msg: Lock table overflow - user id 30032, rstcb 10132264** **See Also: # optional message** **Event ID: 21005**
The message that appears at the end of each e-mailed message	**This e-mail was generated by the server ALARMPROGRAM script on *servername* because something untoward just happened to *eventname*.**

Events in the ph_alert Table

All event alarms that are generated are inserted in the **ph_alert** table in the **sysadmin** database.

You can query the **ph_alert** table on local or remote server to view the recent event alarms for that server. You can write SQL scripts based on the **ph_alert** table to handle event alarms instead of using the scripts controlled by the ALARMPROGRAM configuration parameter.

By default, alerts remain in the **ph_alert** table for 15 days before being purged.

Example

The following example shows an event alarm in the **ph_alert** table:

```
SELECT * FROM ph_alerts WHERE alert_object_type=ALARM;

id                  34
alert_task_id       18
alert_task_seq      10
alert_type          INFO
alert_color         YELLOW
alert_time          2010-03-08 12:05:48
alert_state         NEW
```

```
alert_state_chang+  2010-03-08 12:05:48
alert_object_type   ALARM
alert_object_name   23
alert_message       Logical Log 12 Complete, timestamp: 0x8e6a1.
alert_action_dbs    sysadmin
alert_action
alert_object_info   23001
```

Event Alarm Parameters

Event Alarm Parameters

Event alarms have five parameters that describe each event.

The following table lists the parameters that are part of event alarm.

Table 1. Event Alarm Parameters

Parameter	Description	Data Type
severity	The severity of the event.	integer
class_id	A numeric identifier that classifies the type of event that has occurred.	integer
class_msg	A brief messages that describes the classification of the event.	string
specific_msg	Specific messages that describes the event that occurred.	string
see_also	A reference to a file that contains additional information about the event.	string
uniqueid	A unique event identifier for the specific message.	bigint

Event Severity

An event severity code is a numeric indication of the seriousness of an event. Every event that is included in the message log contains a severity code. The event severity code is the first parameter that is sent to the alarm program. In the **ph_alert** table, the event severity is reflected by a combination of the alert color and the alert type. The event severity codes are listed in the following table.

Table 2. Event Severity Codes

Severity	Description
1	**Not noteworthy**. The event (for example, date change in the message log) is not reported to the alarm program unless ALRM_ALL_EVENTS configuration parameter is enabled. In the **ph_alert** table, the alert color is GREEN and the alert type is INFO.
2	**Information**. No error has occurred, but some routine event completed successfully (for example, checkpoint or log backup completed). In the **ph_alert** table, the alert color is YELLOW and the alert type is INFO.
3	**Attention**. This event does not compromise data or prevent the use of the system; however, the event warrants your attention. For example, one chunk of a mirrored pair goes down. An email is sent to the system administrator. In the **ph_alert** table, the alert color is YELLOW and the alert type is WARNING.
4	**Emergency**. Something unexpected occurred that might compromise data or access to data. For example an assertion failure, or **oncheck** reports data corrupt. Take action immediately. The system administrator is paged when this event severity occurs. In the **ph_alert** table, the alert color is RED and the alert type is ERROR.
5	**Fatal**. Something unexpected occurred and caused the database server to fail. The system administrator is paged when this event severity occurs. In the **ph_alert** table, the alert color is RED and the alert type is ERROR.

Class ID

The class ID is an integer that identifies the event that causes the database server to run your alarm program. The class ID is the second parameter that the database server displays in your alarm program.

The class ID is stored in the **alert_object_name** column in the **ph_alert** table.

Class Message

The class message is a text message briefly describes, or classifies, the event that causes the database server to run your alarm program. The class messages is the third parameter that the database server displays in your alarm program.

Specific Message

The specific message is a text messages the describes in more detail the event that causes the database server to run your alarm program. The specific message is the fourth parameter that the database server displays in your alarm program. For many alarms, the text of this message is the same as the message that is written to the message log for the event.

The specific message is stored in the **alert_message** column in the **ph_alert** table.

See Also Paths

For some events, the database server writes additional information to a file when the event occurs. The path name in this context refers to the path name of the file where the database server writes the additional information.

Event ID

The event ID is a unique number for each specific message. You can use the event ID in custom alarm handling scripts to create responses to specific events.

The event ID is stored in the **alert_object_info** column in the **ph_alert** table.

Event alarm IDs

The class ID for event alarms indicates the type of event. The event ID indicates the specific event.

The following table lists event alarm IDs and messages or where to find more information. Many alarms have additional explanations and user actions. Many of the issues that trigger event alarms also result in messages in the online message log. The location of the message log is specified by the MSGPATH configuration parameter.

Table 1. Event Alarms

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1001	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Page allocation error on '*object*'	The database server detected an inconsistency during the allocation of pages to a table or index. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Dependent upon the nature of the problem found. **User action:** Review the online.log file for appropriate action. You will need to run the **oncheck** utility on the *'dbname:"owner".tabname'* identified in the message. Occasionally, the database server automatically resolves the problem, and this resolution is identified in the online.log file.
Class ID: 1 Event ID: 1002	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Row allocation error on '*object*'	The database server detected an inconsistency during the allocation of a row to a table or index. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Dependent upon the nature of the problem found. **User action:** Review the online.log file for appropriate action. You will need to run the **oncheck** utility on the *'dbname:"owner".tabname'* identified in the message. Occasionally, the database server automatically resolves the problem, and this resolution is identified in the online.log file.
Class ID: 1 Event ID: 1003	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Slot allocation error for '*object*'	The database server detected an inconsistency during row processing. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Dependent upon the nature of the problem found. **User action:** Review the online.log file for appropriate action. You will need to run the **oncheck** utility on the *'dbname:"owner".tabname'* identified in the message. Occasionally, the database server automatically resolves the problem, and this resolution is identified in the online.log file.
Class ID: 1 Event ID: 1004	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error prevented the database server to find the next possible data page in this tblspace.	The database server detected an inconsistency in a bitmap page during the allocation of a row to a table or index. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Dependent upon the nature of the problem found. **User action:** Review the online.log file for appropriate action. Run the **oncheck** utility on the *'dbname:"owner".tabname'* identified in the message.

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1005	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Dropping wrong TBLSpace, requested *tblspace_name* != actual *tblspace_name*	The database server detected a mismatch between the requested and existing tables while attempting to drop a table. No table was dropped. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Online **User action:** Review the online.log file for appropriate action. Run the **oncheck** utility on the *'dbname:"owner".tabname'* identified in the message.
Class ID: 1 Event ID: 1006	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error which may have been caused due to data corruption prevented the database server from altering the bitmap pages for this partition.	The database server encountered a possible data corruption error during a table or index operation to alter bitmap pages. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Online **User action:** Review the online.log file for appropriate action. Run the **oncheck** utility on the *'dbname:"owner".tabname'* identified in the message.
Class ID: 1 Event ID: 1007	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: [3] An internal error which may have been caused due to corrupted bitmap pages as the database server is still in the process of converting them.	The database server encountered an incomplete modification of internal bitmap pages during a table or index operation to alter bitmap pages. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Online **User action:** Note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1008	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error which may have been caused due to unconverted bitmap pages.	The database server encountered a situation where the modification of the internal bitmap pages has not yet completed. during a table or index operation to alter bitmap pages. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Online. **User action:** Note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1009	4	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Page Check Error in *object*	The database server detected inconsistencies while checking a page that was being read into internal buffers. **Online log:** Assertion failure or assertion warning with a description of the problem. **Server state:** Online or offline, depending on how serious the problem is. **User action:** Follow the suggestions in the online log. Typically, run the **oncheck -cD** command on the table mentioned in the class message or on the database.
Class ID: 1 Event ID: 1010	4	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Bad rowid *rowid*	The database server detected an invalid row ID. **Online log:** Assertion warning with a description of where the problem was found. **Server state:** Online. **User action:** Repair the index by running the **oncheck -cI** command on the table mentioned in the class message or on the database.
Class ID: 1 Event ID: 1011	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Closing TBLSpace *tblspace_name*	The database server determined that the table or index is closed. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Online. **User action:** None. The database server will correct the problem automatically.
Class ID: 1 Event ID: 1012	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Cannot recreate index *index_name* for partnum *partition_number*, iserrno = *error_number*	The database server encountered an error that prevents recreating an index. **Online log:** Assertion Failure or Assertion Warning with problem details. **Server state:** Online. **User action:** Review the online.log file for the index information, and then drop and recreate the index manually.

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1013	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to initialize the type of set read operation.	The database server was unable to initialize internal data structures for a set read operation. **Online log:** Assertion Warning with database and table details. **Server state:** Online. **User action:** Review the online.log file for ISAM error codes, and table and database information. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1014	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to read records from the tblspace's pages	The database server encountered an internal error when reading records from a table or index. **Online log:** Assertion Warning with database and table details. **Server state:** Online. **User action:** Review the online.log file for table and database information. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1015	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to read the current record.	The database server encountered an internal error when reading records from a table or index. **Online log:** Assertion Warning with database and table details. **Server state:** Online. **User action:** Review the online.log file for table and database information. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1016	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to initialize the set read buffer.	An internal error was triggered when the database server attempted to initialize a set read buffer. **Online log:** Assertion Warning with database and table details. **Server state:** Online. **User action:** Review the online.log file for table and database information. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1017	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to set the new mode on the bitmap page.	An internal error occurred during the conversion of a bitmap page from an earlier version of the database server. **Online log:** Assertion Warning with problem details. **Server state:** Online. **User action:** None.
Class ID: 1 Event ID: 1018	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was attempting to convert bitmap pages to the correct format.	The database server was unable to correct an error which occurred during a bitmap page conversion. **Online log:** Assertion Warning with problem details. **Server state:** Online. **User action:** Note all circumstances, review the online.log file for additional information, and contact Software Support.
Class ID: 1 Event ID: 1019	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to modify the bitmap pages during light append operation.	The database server encountered an internal error during a light append operation and could not locate the required bitmap page. **Online log:** Assertion Warning with problem details. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1020	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to perform light scan operation.	The database server encountered an internal error while performing a light scan operation. **Online log:** Assertion Warning with problem details. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1021	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while the database server was trying to perform light scan I/O operation.	The database server encountered an internal error while performing a light scan operation. **Online log:** Assertion Warning with problem details. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1022	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to validate light append buffer.	The database server encountered an internal error while performing a light scan operation. **Online log:** Assertion Warning with problem details. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1023	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to write the next record to the page in the light append buffer.	The database server encountered an internal error while performing a light scan operation. **Online log:** Assertion Warning with problem details. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1024	4	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to open a light append for a tblspace.	The database server encountered an internal error during a light append operation on a tblspace. **Online log:** Assertion failure. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1025	4	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to load the first bitmap page for a light append operation.	The database server encountered an internal error during a light append operation. **Online log:** `Assertion Failure : Light Append(Redo/Undo): Can't find bitmap page` **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1026	4	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to write the cached bitmap pages for a light append operation.	The database server encountered an internal error during a light append operation. **Online log:** Assertion failure. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1027	2	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal deadlock database condition was caught by the Lock Manager in the database server.	The database server detected an internal deadlock database condition. **Online log:** Assertion warning identifying the databases and tables involved in the deadlock. **Server state:** Online. **User action:** None.
Class ID: 1 Event ID: 1028	2	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal deadlock database condition was caught by the Lock Manager in the database server.	The database server detected an internal deadlock database condition. **Online log:** Assertion warning identifying the databases and tables involved in the deadlock. **Server state:** Online. **User action:** None.
Class ID: 1 Event ID: 1029	4	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to map the logical page number in the tblspace to its physical location in the chunk.	The database server could not access a table because of an inconsistency between the physical page and its logical page number. **Online log:** Assertion failure with the page information. **Server state:** Online. **User action:** Run the **oncheck -cDI** command on the table mentioned in the class message or on the database, fix any issues reported, and then try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1030	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to allocate the alter information.	The database server encountered an internal error when attempting to read an internal disk structure. **Online log:** Assertion Warning with problem details and table and database information. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1031	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to prepare the list of operations to be performed on a compressed row.	The database server encountered an internal error when it tried to create an internal operations list to transform a compressed version of a row to an uncompressed version of the latest row. **Online log:** Assertion Warning with problem details and table and database information. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1032	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to insert an operation in the list of operations based on the offset in the row where the new operation points to.	The database server encountered an internal error when it tried to create an internal operations list to transform a compressed version of a row to an uncompressed version of the latest row. **Online log:** Assertion Warning with problem details and table and database information. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1033	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it detected an inconsistency with the operation list.	The database server encountered an internal error when it tried to create an internal operations list to transform a compressed version of a row to an uncompressed version of the latest row. **Online log:** Assertion Warning with problem details and table and database information. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1034	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to free the partition header page.	The database server encountered an internal error when attempting to free the header page for a partition. The database server did not free the header page. **Online log:** Assertion Warning with problem details, table and database information, and a specific **oncheck** command to run. **Server state:** Online. **User action:** Review the online.log file for information and run the specified **oncheck** command.
Class ID: 1 Event ID: 1035	3 or 4	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to validate the partition header page.	The database server cannot access a table because of a validation error for the tblspace page. **Online log:** Assertion with details about the table. **Server state:** Online. **User action:** Examine the online log for information about the specified table. Run the **oncheck -pt** command on the table or on the database and correct any errors found. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1036	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to update the special columns list during an alter table command processing.	The database server encountered an internal error when processing the special columns list associated with a table while the table was being altered. **Online log:** Assertion Warning with problem details, table and database information, and a specific **oncheck** command to run. **Server state:** Online. **User action:** Review the online.log file for information and run the specified **oncheck** command.
Class ID: 1 Event ID: 1037	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to log the completion of the alter and remove the associated version information from the tblspace's header page.	The database server encountered an internal error when attempting to alter a table. **Online log:** Assertion Warning with problem details, table and database information, and a specific **oncheck** command to run. **Server state:** Online. **User action:** Review the online.log file for information and run the specified **oncheck** command.

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1038	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it detected a buffer inconsistency.	The database server encountered an internal error during a consistency check of the internal buffers it was manipulating. **Online log:** Assertion Warning with problem details, table and database information, and a specific **oncheck** command to run. **Server state:** Online. **User action:** Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1039	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to construct a forwarded row into a single tuple.	The database server encountered an internal error when processing rows. **Online log:** Assertion Warning with problem details, and table and database information. **Server state:** Online. **User action:** Review the online.log file for more information. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1040	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to read the data from a partition into the set read buffer.	The database server encountered a corrupt record during the process of reading data and was unable to retrieve the data. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file. Some instances of this error require the attention of Software Support.
Class ID: 1 Event ID: 1041	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to read the data row for a given rowid.	The database server encountered a corrupt record during the process of reading data from an index and was unable to retrieve the data. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file for information and run the recommended **oncheck** command. Some instances of this error require the attention of Software Support.
Class ID: 1 Event ID: 1042	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to alter the row in memory to the latest schema.	The database server encountered an internal error while trying to convert an old version of a record to the latest version of the record in an altered table. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file for more information. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 1 Event ID: 1043	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to undo the alter of a bitmap page.	The database server encountered an internal error while trying to revert an operation that had altered an internal bitmap page. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 1 Event ID: 1044	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to undo the addition of special column descriptors from the tblspace's header page.	The database server encountered an internal error while trying to revert an operation that had added information to the internal structure that tracks tables. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1045	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to undo the addition of the new version to a partition.	The database server encountered an internal error while trying to revert an operation that had added information to the internal structure that tracks tables. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 1 Event ID: 1046	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to allocate the file descriptor for a partition number.	The database server encountered an internal error while trying to create a new file descriptor for a table or index. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 1 Event ID: 1047	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: An internal error was reported by the database server when it tried to free the file descriptor for a partition number.	The database server encountered an internal error while trying to release an internal data structure associated with a table or index. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** None. The database server will internally correct the issue.
Class ID: 1 Event ID: 1048	3	Class message: Table failure: *'dbname:"owner".tabname'* Specific message: Error updating table record.	The database server was unable to update a database record for a table that has in-place alters. It was unable to write the new version of the record. **Online log:** Assertion Warning with details of the error encountered and the *database:table* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2001	3 or 4	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: Fragid *fragment_id*, Rowid *rowid* not found for delete in partnum *partition_number*	The database server did not delete a record because it could not find it in the index. **Online log:** Assertion indicating that a DELETE operation failed and details of the table and index where the problem occurred. **Server state:** Online. **User action:** Run the **oncheck -cI** command on the specified table and index, or on the database, and correct any errors found. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 2 Event ID: 2002	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: An internal error was raised due to an inconsistency in the index which is preventing the database server to position on the first record in that index.	The database server detected an inconsistent index and marked it as unusable. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2003	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: An internal error was raised due to an inconsistency in the index which is preventing the database server to read ahead pages in that index.	The database server detected an inconsistent index and marked it as unusable. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2004	4	Class message: Index failure: *'dbname:"owner".tabname-idxname'* Specific message: Page Check Error in *object*	The database server detected inconsistencies with an index. **Online log:** Various messages depending on where the issue was detected. For example: `Possible inconsistencies in a DBSpace TBLSpace Run 'oncheck -cD' on all DBSpace TBLSpaces` **Server state:** Online. **User action:** Review the online.log file for more information and run the recommended **oncheck -cD** command on the database.

ID	Severity	Messages	Explanation
Class ID: 2 Event ID: 2005	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: An internal error occurred during batched index read because the database server had an invalid index key item.	The database server detected an inconsistent index and marked it as unusable. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2006	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: *index_page* log record too large to fit into the logical log buffer. Recommended minimum value for LOGBUFF is *number*.	The server detected that a log record for an index page is too large for the configured logical log buffer size. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and update the onconfig value for LOGBUFF to the recommended value.
Class ID: 2 Event ID: 2007	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: Comparison based on locale '*locale_name*' failed	The database server detected an inconsistent index and marked it as unusable. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2008	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: Comparison failed	The database server detected an inconsistent index and marked it as unusable. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2009	4	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: An internal error occurred while the database server was trying to add a new item to the index.	The database server could not insert a record into an index. **Online log:** Assertion specifying the index and the recommended **oncheck** command to run. **Server state:** Online. **User action:** Examine the online log file and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2010	4	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: An internal error was raised due to an inconsistency in the index which is preventing the database server to position at the correct item in the index.	The database server could not retrieve the correct item in the index because of an inconsistency in the index. **Online log:** Assertion specifying the index and the recommended **oncheck** command to run. **Server state:** Online. **User action:** Examine the online log file and run the recommended **oncheck** command.
Class ID: 2 Event ID: 2011	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: Cannot drop index *index_name* for partnum *partition_number*, iserrno = *error_number*	The database server detected an inconsistent index and marked it as unusable. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information and run the recommended **oncheck** command. Retry the original operation and if it fails again contact Software Support.
Class ID: 2 Event ID: 2012	3	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: An internal error occurred while the database server was trying to mark an index key descriptor as bad.	The database server detected an inconsistent index and marked it as unusable. **Online log:** Assertion Warning with details of the error encountered and the *database:table:index* involved. **Server state:** Online. **User Action:** Review the online.log file for more information, run the recommended **oncheck** command, fix any problems detected, then re-enable the index.

ID	Severity	Messages	Explanation
Class ID: 2 Event ID: 2013	4	Class message: Index failure: *'dbname:"owner".tabname:idxname'* Specific message: An internal error occurred while the database server was trying to delete an item from the index.	The database server could not delete a record from an index. **Online log:** Assertion specifying the index and the recommended **oncheck** command to run. **Server state:** Online. **User action:** Examine the online log file and run the recommended **oncheck** command.
Class ID: 3 Event ID: 3001	3	Class message: Blob failure: *'dbname:"owner".tabname'* Specific message: tb_sockid in blob descriptor is corrupted. Current® table is *'dbname:"owner".tabname'*	
Class ID: 3 Event ID: 3002	3	Class message: Blob failure: *'dbname:"owner".tabname'* Specific message: Incorrect BLOB stamps.	
Class ID: 3 Event ID: 3003	4	Class message: Blob failure: *'dbname:"owner".tabname'* Specific message: BLOB Page Check error at *dbspace_name*	The database server performed a check on pages that are moving between disk and memory and the check failed. **Online log:** Assertion describing the error. **Server state:** Online. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 3 Event ID: 3004	3	Class message: Blob failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while trying to read a blob from a table.	
Class ID: 3 Event ID: 3005	3	Class message: Blob failure: *'dbname:"owner".tabname'* Specific message: An internal error occurred while trying to copy a blob from a table.	
Class ID: 4 Event ID: 4001	4	Class message: Chunk is offline, mirror is active: *chunk_number* Specific message: I/O error, *error_number* Chunk '*chunk_number*' -- Offline	An error has occurred reading from or writing to a chunk. The database server has taken the chunk offline and switched to performing all I/O operations on the active mirrored chunk. **Online log:** Assertion describing the error that occurred. **Server state:** Online. **User action:** Examine the online log for information and fix the error. Run the **onspaces -s** command to recover the offline chunk. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 4 Event ID: 4002	3 or 4	Class message: Chunk is offline, mirror is active: *chunk_number* Specific message: An internal error occurred during physical I/O because the chunk was not opened.	The database server cannot access a chunk and switched to performing all I/O operations on the active mirrored chunk. **Online log:** Assertion describing the error and information about the chunk where the problem occurred. **Server state:** Online. **User action:** Examine the online log, fix any errors, and recover the mirror by using the **onspaces** utility. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 4 Event ID: 4003	3	Class message: Chunk is offline, mirror is active: *chunk_number* Specific message: I/O error, *error_number* Chunk '*chunk_number*' -- Offline (sanity)	

ID	Severity	Messages	Explanation
Class ID: 4 Event ID: 4004	3	Class message: Chunk is offline, mirror is active: *chunk_number* Specific message: Chunk failed sanity check	
Class ID: 4 Event ID: 4005	3	Class message: Chunk is offline, mirror is active: *chunk_number* Specific message: Mirror Chunk *chunk_number* added to space '*space_number*'. Perform manual recovery.	
Class ID: 5 Event ID: 5001	4	Class message: Dbspace is offline: *'dbspace_name'* Specific message: Chunk *chunk_number* is being taken OFFLINE.	The database server took a dbspace offline because of an error in accessing a chunk. **Online log:** Assertion failure if the dbspace was a critical dbspace, such as the rootdbs. Assertion warning if the dbspace is not critical. Both provide information about the chunk and dbspace being taken offline. **Server state:** Online if a non-critical media failure. Offline if a critical media failure. **User action:** Examine the online log file and fix the underlying problem that caused the dbspace to be taken offline. You might need to restore the dbspace.
Class ID: 5 Event ID: 5002	4	Class message: Dbspace is offline: *'dbspace_name'* Specific message: WARNING! Chunk *chunk_number* is being taken OFFLINE for testing.	The database server has taken a dbspace offline as a result of an **onmode** command. **Online log:** Assertion warning indicating that the dbspace has been taken offline. **Server state:** Online. **User action:** None.
Class ID: 6 Event ID: 6016	3	Class message: Internal subsystem failure: *'message'* Specific message: Pool not freed. pool name:*pool_name*, address:*address*	
Class ID: 6 Event ID: 6017	4	Class message: Internal subsystem failure: *'message'* Specific message: CDR Grouper FanOut thread is aborting	A problem occurred with Enterprise Replication. **Online log:** Assertion describing the problem. **Server state:** Online. **User action:** Follow the instructions in the online log.
Class ID: 6 Event ID: 6018	4	Class message: Internal subsystem failure: *'message'* Specific message: CDR Pager: Paging File full: Waiting for additional space in CDR_QDATA_SBSPACE	The storage space of an Enterprise Replication queue is full. **Online log:** Assertion describing the problem. **Server state:** Online. **User action:** Add a chunk to one or more of the sbspaces specified by the CDR_QDATA_SBSPACE configuration parameter.
Class ID: 6 Event ID: 6021	3	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was reported by the database server during conversion when it found some indices in the old format.	
Class ID: 6 Event ID: 6022	3	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was reported by the database server when it checks for any new in-place alter pending in the current server during reversion.	
Class ID: 6 Event ID: 6023	3	Class message: Internal subsystem failure: *'message'* Specific message: Cannot open index '*dbname*:*index_name*', iserrno = *error_number*	

ID	Severity	Messages	Explanation
Class ID: 6 Event ID: 6024	3	Class message: Internal subsystem failure: *'message'* Specific message: Cannot drop index '*dbname*:*index_name*', iserrno = *error_number*	
Class ID: 6 Event ID: 6025	3	Class message: Internal subsystem failure: *'message'* Specific message: Cannot open table '*dbname*:*table_name*', iserrno = *error_number*	
Class ID: 6 Event ID: 6026	3	Class message: Internal subsystem failure: *'message'* Specific message: Cannot drop table '*dbname*:*table_name*', iserrno = *error_number*	
Class ID: 6 Event ID: 6027	3	Class message: Internal subsystem failure: *'message'* Specific message: An error was reported by the database server when it tried to drop the sysmaster database during reversion	
Class ID: 6 Event ID: 6030	3	Class message: Internal subsystem failure: *'message'* Specific message: Invalid or missing name for Subsystem Staging BLOBspace	
Class ID: 6 Event ID: 6033	5	Class message: Internal subsystem failure: *'message'* Specific message: Cache read error	The database server shut down after encountering an error while reading an internal cache. **Online log:** Assertion Failure. **Server State:** Offline. **User action:** Start the database server and try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6034	3	Class message: Internal subsystem failure: *'message'* Specific message: Could not start remote server	
Class ID: 6 Event ID: 6035	3	Class message: Internal subsystem failure: *'message'* Specific message: An error was reported by the database server during the handling of audit trail files.	
Class ID: 6 Event ID: 6036	3	Class message: Internal subsystem failure: *'message'* Specific message: Archive on *dbspaces_list* ABORTED	
Class ID: 6 Event ID: 6037	3	Class message: Internal subsystem failure: *'message'* Specific message: Waiting on BLOBSpace to appear for Logical Recovery	
Class ID: 6 Event ID: 6038	3	Class message: Internal subsystem failure: *'message'* Specific message: An internal error reported by the database server. Users may need to look at the specific message which accompanies with this id.	

ID	Severity	Messages	Explanation
Class ID: 6 Event ID: 6039	3	Class message: Internal subsystem failure: *'message'* Specific message: Wrong page for cleaning deleted items	
Class ID: 6 Event ID: 6040	3	Class message: Internal subsystem failure: *'message'* Specific message: Buffer in wrong state for cleaning deleted items	
Class ID: 6 Event ID: 6041	5 or 3	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was detected by the Buffer Manager in the database server.	For severity 5, the database server buffer manager encountered an internal error and either shut down or corrected the problem. **Online log:** Assertion warning or an assertion failure with a description of the operation being performed at the time of the error. Typically, an assertion warning shows that the error was internally corrected. **Server State:** Offline if the error was unrecoverable. Online if the error was corrected. **User action:** If the error was unrecoverable, start the database server and try the operation again. If the operation fails again, note all circumstances and contact Software Support. No action is required if the error was internally corrected by the database server.
Class ID: 6 Event ID: 6042	5 or 2	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was reported by the database server when it detected an inconsistency with the internal buffer queues.	For severity 5, the database server detected an inconsistency during the processing of internal buffer queues and either shut down or corrected the problem. **Online log:** Assertion warning or an assertion failure with a description of the operation being performed at the time of the error. Typically, an assertion warning shows that the error was internally corrected. **Server State:** Offline if the error was unrecoverable. Online if the error was corrected. **User action:** If the error was unrecoverable, start the database server and try the operation again. If the operation fails again, note all circumstances and contact Software Support. No action is required if the error was internally corrected by the database server.
Class ID: 6 Event ID: 6043	3	Class message: Internal subsystem failure: *'message'* Specific message: Internal file error	
Class ID: 6 Event ID: 6044	3	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was corrected automatically by the database server when it tried to save the log buffer into a system log buffer.	
Class ID: 6 Event ID: 6045	5	Class message: Internal subsystem failure: *'message'* Specific message: Logical logging error for '*object*' in *'space'*	The database server shut down because of an error while processing logical logs. **Online log:** Assertion failure with a description of the operation and logical log information. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6046	4	Class message: Internal subsystem failure: *'message'* Specific message: Page Check Error in *object*	The database server detected inconsistencies in the data. **Online log:** Various outputs depending upon where the issue was detected. For example: `Possible inconsistencies in a DBSpace TBLSpace Run 'oncheck -cD' on all DBSpace TBLSpaces` **Server state:** Online. **User action:** Examine the online log file and run the recommended **oncheck -cD** command on the database.

ID	Severity	Messages	Explanation
Class ID: 6 Event ID: 6047	3	Class message: Internal subsystem failure: *'message'* Specific message: Errors occurred while recreating indexes	
Class ID: 6 Event ID: 6049	5	Class message: Internal subsystem failure: *'message'* Specific message: Lock types *lock_type* and *lock_type* should never be merged	The database server shut down after attempting to merge incompatible locks. **Online log:** Assertion failure with the lock types that the database server was attempting to merge. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6050	5	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was reported by the database server when it detected some corruption in the lock free list chain.	The database server shut down after detecting corruption of an internal structure that manages an internal list of free locks. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6051	3	Class message: Internal subsystem failure: *'message'* Specific message: ERROR - NO 'waitfor' locks in Critical Section!!!	
Class ID: 6 Event ID: 6052	3	Class message: Internal subsystem failure: *'message'* Specific message: Internal Tblspace error	
Class ID: 6 Event ID: 6053	3	Class message: Internal subsystem failure: *'message'* Specific message: Session does not have exclusive access to partition *partition_name*. Request to drop the partition ignored.	
Class ID: 6 Event ID: 6054	3	Class message: Internal subsystem failure: *'message'* Specific message: Error building 'sysmaster' database.	
Class ID: 6 Event ID: 6055	3	Class message: Internal subsystem failure: *'message'* Specific message: Setread error on SMI Table, partnum *partition_number*	
Class ID: 6 Event ID: 6056	3	Class message: Internal subsystem failure: *'message'* Specific message: Comparison based on locale '*locale_name*' failed	
Class ID: 6 Event ID: 6057	2	Class message: Internal subsystem failure: *'message'* Specific message: DBSPACETEMP internal list not initialized, using default	The database server did not create the necessary structures for holding the DBSPACETEMP information. **Online log:** Message stating that the internal DBSPACETEMP list was not initialized. **Server state:** Online. **User action:** None.

ID	Severity	Messages	Explanation
Class ID: 6 Event ID: 6058	3	Class message: Internal subsystem failure: *'message'* Specific message: A data source accessed using a gateway (*gateway_name*) might be in an inconsistent state	
Class ID: 6 Event ID: 6059	3	Class message: Internal subsystem failure: *'message'* Specific message: Prepared participant site *site_name* not responding	
Class ID: 6 Event ID: 6060	5	Class message: Internal subsystem failure: *'message'* Specific message: Thread exited with *number* buffers held	The database server shut down after detecting that a thread is holding one or more buffers. **Online log:** Assertion failure with the number of buffers being held by the thread. **Server State:** Offline. **User action:** Bring the database server online. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6061	3	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was automatically corrected by the database server when it detected that the undo log for the transaction was not applicable.	
Class ID: 6 Event ID: 6062	3	Class message: Internal subsystem failure: *'message'* Specific message: Internal Error - Freeing transaction entry that still holds locks!	While freeing resources associated with a transaction, the database server detected that the transaction is holding locks. In most circumstances the database server can release these locks. **Online log:** Assertion warning with the transaction and a statement that the database server internally corrected the problem. **Server State:** Online. **User action:** If the database server shut down, start the database server.
Class ID: 6 Event ID: 6063	3	Class message: Internal subsystem failure: *'message'* Specific message: User thread not on TX wait list	
Class ID: 6 Event ID: 6064	3	Class message: Internal subsystem failure: *'message'* Specific message: Due to a heuristic decision, the work done on behalf of the specified transaction branch might have been heuristically completed or committed or rolled back or partially committed and partially rolled back.	
Class ID: 6 Event ID: 6065	3	Class message: Internal subsystem failure: *'message'* Specific message: Errors occurred while recreating indexes	
Class ID: 6 Event ID: 6066	3	Class message: Internal subsystem failure: *'message'* Specific message: An internal error is reported by the database server when it has checked all sites to see if a heuristic rollback was the reason for the failure.	

ID	Severity	Messages	Explanation
Class ID: 6 Event ID: 6067	5	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (Recursive exception) has caused the database server processes to terminate unexpectedly.	The database server detected recursive calls to exception handling and immediately shut down to avoid an infinite loop. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6068	5	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (Internal exception) has caused the database server processes to terminate unexpectedly.	The database server shut down due to an unrecoverable internal error. **Online log:** Assertion failure with information about the exception that caused the problem. **Server State:** Offline. **User action:** Start the database server. Look at the exception information in the assertion failure file. If the exception relates to a user-defined routine, investigate and correct the user-defined routine. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6069	5	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (Master daemon died) has caused the database server processes to terminate unexpectedly.	The master daemon **oninit** process stopped and the database server shut down. This error can be caused by the termination of operating system processes. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. Be careful when terminating operating system processes.
Class ID: 6 Event ID: 6070	5	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (VP died) has caused the database server processes to terminate unexpectedly.	An **oninit** process stopped and the database server shut down. This error can be caused by the termination of operating system processes. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. Be careful when terminating operating system processes.
Class ID: 6 Event ID: 6071	5	Class message: Internal subsystem failure: *'message'* Specific message: ERROR: can not fork secondary Server thread (MACH11 Shutdown)	The secondary server shut down but was unable to create a thread to shut down normally. **Online log:** `DR: Shutting down the server. ERROR: can not fork secondary Server thread (MACH11 Shutdown) Can not run onmode -ky PANIC: Attempting to bring system down.` **Server State:** Offline. **User action:** None.
Class ID: 6 Event ID: 6072	3	Class message: Internal subsystem failure: *'message'* Specific message: Generic unique event id when the server failed to fork a new thread.	
Class ID: 6 Event ID: 6073	3	Class message: Internal subsystem failure: *'message'* Specific message: An error was reported by the database server when it could not initialize GLS for starting a session.	
Class ID: 6 Event ID: 6074	3	Class message: Internal subsystem failure: *'message'* Specific message: WARNING: mt_aio_wait: errno == EINVAL	
Class ID: 6 Event ID: 6075	5	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (KAIO) has caused the database server processes to terminate unexpectedly.	The database server shut down because of an error in the KAIO subsystem. **Online log:** Assertion failure with the specific operation that failed. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.

ID	Severity	Messages	Explanation
Class ID: 6 Event ID: 6100		Generic event for when the database server implicitly raises an assert warning.	A generic internal error occurred. **Online log:** Assertion warning with problem details. **Server State:** Online. **User action:** Look at the online log and take any recommended corrective action. The database server might correct the problem automatically. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6300		Generic event for when the database server implicitly raises an assert failure.	A generic internal error occurred. **Online log:** Assertion failure with problem details. **Server State:** Online. **User action:** Look at the online log and take any recommended corrective action. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6500		Generic event for when the database server terminates unexpectedly due to an internal error condition.	An internal error occurred and the database server shut down. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. Examine the assertion failure file for more information about what happened. If possible, fix any problems identified and try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7001	3	Class message: Database server initialization failure Specific message: TABLOCKS log record too large to fit into the logical log buffer. Recommended minimum value for LOGBUFF is *size*. I-STAR(C) begins prepare log record too large to fit into the logical log buffer. Recommended minimum value for LOGBUFF is *size*. Partition blob log record too large to fit into the logical log buffer. Recommended minimum value for LOGBUFF is *size*. Alter table special column desc log record too large to fit into the logical log buffer. Recommended minimum value for LOGBUFF is *size*.	
Class ID: 7 Event ID: 7002	4	Class message: Database server initialization failure Specific message: Unable to extend *number* reserved pages for checkpoint in ROOT chunk. Unable to extend *number* reserved pages for log in ROOT chunk.	The database server could not start because it could not allocate more space for internal structures in the initial root chunk. **Online log:** Assertion. **Server state:** Offline. **User action:** Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7003	4	Class message: Database server initialization failure Specific message: An internal error occurred during conversion. Users may need to take a look at the specific messages for further action.	The database server could not start during an upgrade because an internal error occurred during the conversion process. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Look at the online log and the specific message and take the necessary corrective action. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7004	4	Class message: Database server initialization failure Specific message: An internal error occurred while trying to convert the database tblspace.	The database server cannot start because of an internal error when trying to convert the database tblspace, which holds information about the databases in the instance. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Contact Software Support.
Class ID: 7 Event ID: 7005	4	Class message: Database server initialization failure Specific message: An internal error occurred while trying to convert blob free map pages.	The database server cannot start because of an internal error when trying to convert blobspace free-map pages. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Contact Software Support.

ID	Severity	Messages	Explanation
Class ID: 7 Event ID: 7006	4	Class message: Database server initialization failure Specific message: Cannot Open Logical Log.	The database server cannot start because it is still restoring physical or logical logs. This situation can occur if the **onmode -m** or **onmode -s** command is run before the restore is complete. **Online log:** Assertion describing the error. **Server state:** Recovering and starting. **User action:** Run the **onmode -m** or **onmode -s** command after the restore is complete.
Class ID: 7 Event ID: 7007	4	Class message: Database server initialization failure Specific message: Logical Log File not found.	The database server cannot start because a logical log file is missing. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Restore the database server from a backup.
Class ID: 7 Event ID: 7008	3	Class message: Database server initialization failure Specific message: WARNING! LTXHWM is set to 100%. This long transaction high water mark will never be reached. Transactions will not be aborted automatically by the server, regardless of their length.	
Class ID: 7 Event ID: 7009	4	Class message: Database server initialization failure Specific message: A Physical or Logical Restore is active.	The database server cannot start because it is still restoring physical or logical logs. This situation can occur if the **onmode -m** or **onmode -s** command is run before the restore is complete. **Online log:** Assertion describing the error. **Server state:** Recovering and starting. **User action:** Run the **onmode -m** or **onmode -s** command after the restore is complete.
Class ID: 7 Event ID: 7010	4	Class message: Database server initialization failure Specific message: *root_dbspace* has not been physically recovered.	The database server cannot start because the restore was interrupted before the rootdbs was physically restored. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Restore the rootdbs.
Class ID: 7 Event ID: 7011	4	Class message: Database server initialization failure Specific message: *dbspace* has not been physically recovered.	The database cannot start because a dbspace is not physically restored. This situation can occur if the database server is attempted to be started before a restore is complete. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Wait until the restore is complete before starting the database server.
Class ID: 7 Event ID: 7012	4	Class message: Database server initialization failure Specific message: *dbspace* not recovered from same archive backup as *dbspace*.	The database server cannot start because a dbspace was not restored successfully. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Recover the dbspace from a backup and roll forward the necessary logs to bring the dbspace to the correct point in time.
Class ID: 7 Event ID: 7013	4	Class message: Database server initialization failure Specific message: Log *log_number* not found.	The database server cannot start because a restore is not complete. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Wait until the restore is complete before starting the database server.
Class ID: 7 Event ID: 7014	4	Class message: Database server initialization failure Specific message: Logical restore cannot be skipped. Perform a logical restore.	The database server cannot start because a logical restore is not complete. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Perform a logical restore (for example, by using the **onbar -r -l** command) and start the database server in quiescent or online mode.

ID	Severity	Messages	Explanation
Class ID: 7 Event ID: 7015	4	Class message: Database server initialization failure Specific message: Cannot change to On-Line or Quiescent mode.	The database server cannot start because of an error during fast or full recovery. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Examine the online log for more information. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7016	4	Class message: Database server initialization failure Specific message: Cannot Open Primary Chunk '*chunk_number*'.	The database server cannot start because it could not access a primary chunk. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Examine the online log for more information. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7017	4	Class message: Database server initialization failure Specific message: The chunk '*chunk_number*' must have owner-ID "owner_id" and group-ID "*group_id*".	The database server cannot start because the owner and group of a chunk path are not correct. **Online log:** Assertion describing the problem. **Server state:** Offline. **User action:** Correct the permissions on the chunk path mentioned in the specific message. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7018	4	Class message: Database server initialization failure Specific message: The chunk '*chunk_number*' must have READ/WRITE permissions for owner and group (660).	The database server cannot start because the permissions on a chunk path are not correct. **Online log:** Assertion describing the problem. **Server state:** Offline. **User action:** Correct the permissions on the chunk path mentioned in the specific message. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7019	4	Class message: Database server initialization failure Specific message: Memory allocation error.	The database server cannot start because it failed to allocate enough memory. **Online log:** **Server state:** Offline. **User action:** Ensure that enough memory is available for the configuration you have specified for the database server. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7020	4	Class message: Database server initialization failure Specific message: The chunk '*chunk_number*' will not fit in the space specified.	The database server cannot start because there is insufficient space to create the specified chunk. **Online log:** Assertion describing the problem. **Server state:** Offline. **User action:** Specify a smaller size for the chunk or free additional space for the chunk.
Class ID: 7 Event ID: 7021	4	Class message: Database server initialization failure Specific message: *device_name*: write failed, file system is full.	The database server cannot start because the file system does not have free space. **Online log:** Assertion describing the problem. **Server state:** Offline. **User action:** Ensure the file system mentioned in the specific message has enough space. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7022	3	Class message: Database server initialization failure Specific message: An error occurred while the database server was creating the SMI database.	

ID	Severity	Messages	Explanation
Class ID: 7 Event ID: 7023	4	Class message: Database server initialization failure Specific message: Unable to create boot strap config file - '*file_name*'	The database server cannot start because it could not create a configuration file. **Online log:** Assertion describing the error. **Server state:** Offline. **User action:** Examine the online log for more information and fix the problem. The problem might be incorrect permissions on a directory. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 7 Event ID: 7024	3	Class message: Database server initialization failure Specific message: 'sysmaster' database will not be built/checked	
Class ID: 7 Event ID: 7025	3	Class message: Database server initialization failure Specific message: WARNING! Physical Log size *size* is too small. Physical Log overflows may occur during peak activity. Recommended minimum Physical Log size is *number* times maximum concurrent user threads.	
Class ID: 7 Event ID: 7026	3	Class message: Database server initialization failure Specific message: WARNING! Logical log layout may cause __ISN__ to get into a locked state. Recommended smallest logical log size is *number* times maximum concurrent user threads.	
Class ID: 7 Event ID: 7027	3	Class message: Database server initialization failure Specific message: WARNING! Buffer pool size may cause __ISN__ to get into a locked state. Recommended minimum buffer pool size is *number* times maximum concurrent user threads.	
Class ID: 7 Event ID: 7028	3	Class message: Database server initialization failure Specific message: Checkpoint log record may not fit into the logical log buffer. Recommended minimum value for LOGBUFF is *size*.	
Class ID: 7 Event ID: 7029	3	Class message: Database server initialization failure Specific message: Temp transaction not NULL.	
Class ID: 9 Event ID: 9001	4	Class message: Physical recovery failure Specific message: Physical log recovery error	The physical recovery of the database server failed. **Online log:** Assertion failure with a description of the problem. **Server state:** Online. **User action:** Retry the operation or restore from a backup.
Class ID: 10 Event ID: 10001	3 or 4	Class message: Logical recovery failure Specific message: Rollback error *error_number*	Logical recovery failed because the database server could not roll back a transaction. **Online log:** Assertion with details of the error and the log or log record where the problem occurred. **Server state:** Online or offline, depending on the error. **User action:** Examine the online log file for more information and run any recommended commands, such as an **oncheck** command. Retry the original operation. If the operation fails again, note all circumstances and contact Software Support.

ID	Severity	Messages	Explanation
Class ID: 10 Event ID: 10002	4	Class message: Logical recovery failure Specific message: Logical Recovery ABORTED.	The logical recovery of the database server failed. **Online log:** Assertion warning with information about the log record. Assertion failure with information about the log record if the failure is associated with a critical dbspace. **Server state:** Online if the dbspace is not critical. Offline if the dbspace is critical. **User action:** Examine the online log to determine the appropriate action, for example, you might need to restart the warm restore.
Class ID: 10 Event ID: 10003	4	Class message: Logical recovery failure Specific message: Log record (*log_subsystem*:*log_type*) in log *log_number*, offset *log_position* was not rolled back	Logical recovery encountered an internal error while rolling back a transaction. **Online log:** Message describing the log record. **Server state:** Online. **User action:** Examine the online log and determine the appropriate action, for example, resubmit the transaction.
Class ID: 10 Event ID: 10004	3	Class message: Logical recovery failure Specific message: Logical Logging error for '*log_subsystem*:*log_type*' in '*object*'	
Class ID: 10 Event ID: 10005	4	Class message: Logical recovery failure Specific message: An internal error occurred while trying to apply the log records during logical log recovery.	Logical recovery failed. **Online log:** Assertion warning with information about the log record. **Server state:** Depends on the failure. **User action:** Examine the online log and determine the appropriate action, for example, restart the warm restore.
Class ID: 10 Event ID: 10006	3 or 4	Class message: Logical recovery failure Specific message: An internal error occurred when the database server tried to find the file descriptor for the tblspace.	Logical recovery failed because the database server could not find an internal file descriptor for a partition. **Online log:** Assertion indicating for which table the error occurred and instructions to run the **oncheck** command. **Server state:** Online. **User action:** Run the **oncheck -cDI** command for the table mentioned in the online log or for the database.
Class ID: 11 Event ID: 11001	3	Class message: Cannot open chunk: *'pathname'* Specific message: Cannot Open Mirror Chunk '*chunk_number*', errno = *error_number*	
Class ID: 11 Event ID: 11002	3	Class message: Cannot open chunk: *'pathname'* Specific message: Cannot Open Primary Chunk '*chunk_number*', errno = *error_number*	
Class ID: 12 Event ID: 12001	3	Class message: Cannot open dbspace: *'dbspace_name'* Specific message: ERROR: DBspace *dbspace_name* not found among table *table_name* fragments.	
Class ID: 13 Event ID: 13001	2	Class message: Performance improvement possible Specific message: The number of configured CPU poll threads exceeds number of CPU VPs specified in 'VPCLASS cpu'. NETTYPE '*protocol*' poll threads started on NET VPs.	The database server detected a configuration mismatch between the number of CPU virtual processors and the number of requested CPU poll threads during server initialization. **Online log:** Performance warning about the configuration mismatch. The database server uses NET virtual processors instead. **Server state:** Online. **User action:** Check the configuration of the server.

ID	Severity	Messages	Explanation
Class ID: 13 Event ID: 13002	2	Class message: Performance improvement possible Specific message: Transaction table overflow due to parallel recovery.	An internal structure is not large enough to process the logical log. The database server will postpone the log processing until more space exists within the structure. **Online log:** Warning message indicating that the transaction processing was delayed. **Server state:** Online. **User action:** None.
Class ID: 14 Event ID: 14001	3	Class message: Database failure. *'dbname'* Specific message: ''*dbname*" - Error *error_number* during logging mode change.	
Class ID: 15 Event ID: 15001	3	Class message: High-Availability Data-Replication failure Specific message: DR: Turned off on secondary server	
Class ID: 15 Event ID: 15002	3	Class message: High-Availability Data-Replication failure Specific message: DR: Turned off on primary server	
Class ID: 15 Event ID: 15003	3	Class message: High-Availability Data-Replication failure Specific message: DR: Cannot connect to secondary server	
Class ID: 15 Event ID: 15004	3	Class message: High-Availability Data-Replication failure Specific message: DR: Received connection request from remote server when DR is not Off [Local type: *type*, Current state: *state*] [Remote type: *type*]	
Class ID: 15 Event ID: 15005	3	Class message: High-Availability Data-Replication failure Specific message: DR: Received connection request before physical recovery completed.	
Class ID: 15 Event ID: 15006	3	Class message: High-Availability Data-Replication failure Specific message: DR: Local and Remote server type and/or last change (LC) incompatible [Local type: *type*, LC: *type*] [Remote type: *type*, LC: *type*]	
Class ID: 16 Event ID: 16001	2	Class message: Backup completed: *'dbspace_list'* Specific message: Archive on *dbspace_list* completed without being recorded.	An archive completed, but the server detected corrupted pages during the archive. **Online log:** Message indicating that the backup is complete but that corrupted pages have been detected. **Server state:** Online. **User action:** Do not use this backup. Use an earlier backup to immediately restore the bad chunks.

ID	Severity	Messages	Explanation
Class ID: 16 Event ID: 16002	2	Class message: Backup completed: *'dbspace_list'* Specific message: Archive on *dbspace_list* Completed with *number* corrupted pages detected.	An archive completed, but the server detected corrupted pages during the archive. **Online log:** Message indicating that the backup is complete but that corrupted pages have been detected. **Server state:** Online. **User action:** Do not use this backup. Use an earlier backup with 0 bad pages to immediately restore the bad chunks.
Class ID: 16 Event ID: 16003	2	Class message: Backup completed: *'dbspace_list'* Specific message: Archive on *dbspace_list* Completed	An archive completed for the dbspaces listed. **Online log:** Message indicating that the backup is complete for the dbspaces listed. **Server state:** Online. **User action:** None.
Class ID: 17 Event ID: 17001	4	Class message: Backup aborted: *'dbspace_list'* Specific message: Archive detects that page *chunk_number*:*page_offset* is corrupt.	The database server detected corruption and stopped the backup. **Online log:** Assertion describing the problem. **Server state:** Online. **User action:** Examine the online log for information about the corruption. Try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 17 Event ID: 17002	3	Class message: Backup aborted: *'dbspace_list'* Specific message: Page %d:%d of partition *partition_number* not archived.	
Class ID: 18 Event ID: 18001	2	Class message: Log backup completed: *log_number* Specific message: Logical Log *log_number* - Backup Completed	The logical log was backed up. **Online log:** Message identifying the log number of the backed up logical log. **Server state:** Online. **User action:** None.
Class ID: 19 Event ID: 19001	3	Class message: Log backup aborted: *log_number* Specific message: Logical Log *log_number* - Backup Aborted *message*	
Class ID: 20 Event ID: 20001	3	Class message: Logical logs are full—backup is needed Specific message: Logical Log Files are Full -- Backup is Needed	
Class ID: 20 Event ID: 20002	3	Class message: Logical logs are full—backup is needed Specific message: Waiting for Next Logical Log File to be Freed	
Class ID: 20 Event ID: 20003	3	Class message: Logical logs are full—backup is needed Specific message: Logical Log Files are almost Full -- Backup is Needed. In Data replication scenario, this could block failure-recovery of the paired server.	
Class ID: 21 Event ID: 21001	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Archive arcbu_next_tbuf() – Buffer Overflow	

ID	Severity	Messages	Explanation
Class ID: 21 Event ID: 21002	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Archive tcp_logbu_hdr() – Buffer Overflow	
Class ID: 21 Event ID: 21003	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Archive tcp_logbu_trl() – Buffer Overflow	
Class ID: 21 Event ID: 21004	2 or 5	Class message: Database server resource overflow: *'resource_name'* Specific message: Physical log file overflow	For severity 5, the physical log file is full and needs to overflow. If this happens during recovery, the database server attempts to extend the physical log. **Online log:** Assertion failure if the database server is either not in recovery or is unable to extend the physical log. Assertion warning if the database server is in recovery and extends the physical log. **Server State:** Offline. **User action:** None.
Class ID: 21 Event ID: 21005	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Lock table overflow - user id %d, session id %d	
Class ID: 21 Event ID: 21006	5	Class message: Database server resource overflow: *'resource_name'* Specific message: Logical log buffer overflow detected	The database server shut down because the logical log buffer is full. **Online log:** Assertion failure with the log record size and the buffer size. **Server State:** Offline. **User action:** Increase the value of the LOGBUFF configuration parameter in the onconfig file. Start the database server.
Class ID: 21 Event ID: 21007	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Llog logbu_logfile() – Buffer Overflow	
Class ID: 21 Event ID: 21008	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Llog logbu_bpage() – Buffer Overflow	
Class ID: 21 Event ID: 21009	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Unable to allocate a user thread for user id *user_ID*	
Class ID: 21 Event ID: 21010	3	Class message: Database server resource overflow: *'resource_name'* Specific message: Unable to allocate a transaction for user id *user_ID*, session id *session_ID*	
Class ID: 21 Event ID: 21014	3	Class message: OnLine resource overflow: Locks; Specific message: SID='*session id*' User ID='*uid*' NAME='*user name*' PID='*process id*'	The lock limit within this session is reached. The current transaction is terminated. **Online log:** Session *session id* has exceeded the session limit of *number* locks. **Server state:** Online **User action:** Reduce your transaction size.

ID	Severity	Messages	Explanation
Class ID: 21 Event ID: 21016	3	Class message: OnLine resource overflow: Memory; Specific message: Session info: '*session id username*@*hostname*' pid '*pid*'	The memory limit within this session is reached. The current session is terminated. **Online log:** Session *session id* has exceeded the session limit of *size* of memory. **Server state:** Online **User action:** Reduce session memory consumption.
Class ID: 21 Event ID: 21017	3	Class message: OnLine resource overflow: Tempspace; Specific message: Session info: '*session id username*@*hostname*' pid '*pid*'	The temporary space limit within this session is reached. The current session is terminated. **Online log:** Session *session id* has exceeded the session limit of *size* of temporary space. **Server state:** Online **User action:** Reduce your data size.
Class ID: 21 Event ID: 21018	3	Class message: OnLine resource overflow: Log Space; Specific message: Session info: '*session id username*@*hostname*' pid '*pid*'	The log space limit within this session is reached. The current transaction is terminated. **Online log:** Session *session id* has exceeded the session limit of *size* of log space. **Server state:** Online **User action:** Reduce your transaction size.
Class ID: 21 Event ID: 21019	3	Class message: OnLine resource overflow: Transaction Time; Specific message: Session info: '*session id username*@*hostname*' pid '*pid*'	The transaction time limit within this session is reached. The current session is terminated. **Online log:** Session *session id* has exceeded the session limit of *seconds* of transaction time. **Server state:** Online **User action:** Reduce idle time for open transactions.
Class ID: 22 Event ID: 22001	3	Class message: Long transaction detected Specific message: Blocking on XA transaction, tx *transaction_number*, till it is cleaned up.	
Class ID: 22 Event ID: 22002	3	Class message: Long transaction detected Specific message: Continuing Long Transaction (for COMMIT): tx:	
Class ID: 22 Event ID: 22003	3	Class message: Long transaction detected Specific message: Aborting Long Transaction: tx:	
Class ID: 23 Event ID: 23001	2	Class message: Logical log *'number'* complete Specific message: Logical Log *log_number* Complete, timestamp: *timestamp*.	The logical log is full, and no more transactions can be written to it. **Online log:** Message indicating that the logical log is full. **Server state:** Online. **User action:** None.
Class ID: 24 Event ID: 24001	3	Class message: Unable to allocate memory Specific message: Generic unique event id when the server failed to allocate memory for starting a new thread.	
Class ID: 24 Event ID: 24002	3	Class message: Unable to allocate memory Specific message: Warning: unable to allocate requested big buffer of size *size*	

ID	Severity	Messages	Explanation
Class ID: 24 Event ID: 24003	3	Class message: Unable to allocate memory Specific message: The database server tried to allocate a shared memory virtual segment before it was actually needed, in accordance with the setting of the SHMVIRT_ALLOCSEG configuration parameter - but the segment could not be added. Next failure message will be printed in 30 minutes.	
Class ID: 24 Event ID: 24004	3	Class message: Unable to allocate memory Specific message: out of message shared memory	
Class ID: 24 Event ID: 24005	3	Class message: Unable to allocate memory Specific message: out of message shared memory	
Class ID: 24 Event ID: 24006	3	Class message: Unable to allocate memory Specific message: out of virtual shared memory	
Class ID: 24 Event ID: 24007	3	Class message: Unable to allocate memory Specific message: No memory available for page cleaners	
Class ID: 24 Event ID: 24008	3	Class message: Unable to allocate memory Specific message: kysearch(): Memory allocation error	
Class ID: 24 Event ID: 24009	3	Class message: Unable to allocate memory Specific message: Lock table overflow - user id *user_ID*, session id *session_ID*	
Class ID: 24 Event ID: 24010	3	Class message: Unable to allocate memory Specific message: Unable to allocate a user thread for user id *user_ID*	
Class ID: 24 Event ID: 24011	3	Class message: Unable to allocate memory Specific message: Unable to allocate a transaction for user id *user_ID*, session id *session_ID*	
Class ID: 26 Event ID: 26001	3	Class message: Dynamically added log file *logid* Specific message: Dynamically added log file *logid* to DBspace *dbspace_name*	

ID	Severity	Messages	Explanation
Class ID: 27 Event ID: 27001	4	Class message: Log file required Specific message: ALERT: The oldest logical log (*log_number*) contains records from an open transaction (*transaction_number*). Logical logging will remain blocked until a log file is added. Add the log file with the onparams -a command, using the -i (insert) option, as in: onparams -a -d *dbspace* -s *size* -i Then complete the transaction as soon as possible.	The database server needs an additional log file to continue processing. **Online log:** `ALERT: The oldest logical log (log_number) contains records from an open transaction (transaction_number). Logical logging will remain blocked until a log file is added. Add the log file with the onparams -a command, using the -i (insert) option, as in: onparams -a -d dbspace -s size -i Then complete the transaction as soon as possible.` **Server state:** Online. **User action:** Add a new logical log.
Class ID: 28 Event ID: 28001	4	Class message: No space for log file Specific message: ALERT: Because the oldest logical log (*log_number*) contains records from an open transaction (*transaction_number*), the server is attempting to dynamically add a log file. But there is no space available. Please add a DBspace or chunk. Then complete the transaction as soon as possible.	The database server cannot dynamically add an additional logical log file because not enough space is available. **Online log:** Assertion warning indicating that there is not enough space available for an additional logical log file. **Server state:** Online. **User action:** Add a new logical log file or additional space.
Class ID: 28 Event ID: 28002	4	Class message: No space for log file Specific message: Warning - Enterprise Replication is attempting to dynamically add a log file. But there is no space available. The replay position may overrun.	The database server cannot dynamically add an additional logical log file because not enough space is available. **Online log:** Assertion warning indicating that there is not enough space available for an additional logical log file. **Server state:** Online. **User action:** Add a new logical log file or additional space.
Class ID: 29 Event ID: 29001	2	Class message: Internal subsystem: *subsystem* Specific message: Skipped existing audit trail files *file_name* to *file_name*.	The auditing subsystem needs to change to a new output file. **Online log:** Message indicating that the audit file changed, skipping over existing files. **Server state:** Online. **User action:** None.
Class ID: 30 - 39	2, 3, or 4	Enterprise Replication events. See Enterprise Replication Event Alarms.	
Class ID: 40 Event ID: 40001	3	Class message: RSS alarm Specific message: RSS *server_name* added	
Class ID: 40 Event ID: 40002	3	Class message: RSS alarm Specific message: Password for RSS Source *server_name* changed	
Class ID: 40 Event ID: 40003	3	Class message: RSS alarm Specific message: RSS *server_name* deleted	
Class ID: 40 Event ID: 40004	3	Class message: RSS alarm Specific message: RSS *server_name* log replay position is falling too far behind RSS Source	
Class ID: 40 Event ID: 40005	3	Class message: RSS alarm Specific message: RSS *server_name* is not acknowledging log transmission	

ID	Severity	Messages	Explanation
Class ID: 40 Event ID: 40006	3	Class message: RSS alarm Specific message: Error receiving a buffer from RSS *server_name* - shutting down	
Class ID: 40 Event ID: 40007	3	Class message: RSS alarm Specific message: Delay or Stop Apply: I/O write error: *error_number error_description*.	
Class ID: 40 Event ID: 40008	3	Class message: RSS alarm Specific message: Delay or Stop Apply: Thread exiting due to error.	
Class ID: 41 Event ID: 41001	3	Class message: SDS alarm Specific message: ERROR: Removing SDS Node *server_name* has timed out - removing	
Class ID: 42 Event ID: 42001	1	Class message: Event occurred	The database server encountered an error while validating the tablespace page. **Online log:** Assertion warning with details of the table. **Server state:** Online. **User action:** Examine the online log to determine which *database.owner.tablename* the issue occurred on. Run the **oncheck -pt** command on the table. Correct any errors identified by the **oncheck** utility and retry the operation. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 43 Event ID: 43001	3	Class message: Connection Manager alarm Specific message: CM:Session for Connection manager *name* terminated abnormally	
Class ID: 43 Event ID: 43002	3	Class message: Connection Manager alarm Specific message: The FOC setting *FOC_String* for Connection Manager *CM_Name* does not match the FOC setting for the other Connection Managers that are configured to arbitrate failover for the cluster. If this Connection Manager becomes the active arbitrator, its FOC will not match the previous FOC policy.	
Class ID: 44 Event ID: 44001	3	Class message: DBSpace is full: *dbspace_name* Specific message: WARNING: *dbspace_type dbspace_name* is full	
Class ID: 45 Event ID: 45001	3	Class message: partition *'partition_name'*: no more extents Specific message: Partition *'partition_name'*: No more extents	
Class ID: 46 Event ID: 46001	3	Class message: partition *'partition_name'*: no more pages Specific message: Partition *'partition_name*: No more pages	

ID	Severity	Messages	Explanation
Class ID: 47 - 71	3 or 4	Enterprise Replication events. See Enterprise Replication Event Alarms.	
Class ID: 72 Event ID: 72001	2	Class message: Audit trail is switched to a new file. Specific message: Audit trail switched to *file_name*	The auditing subsystem is switching to a new output file. **Online log:** Message providing the file name of the new output file. **Server state:** Online. **User action:** None.
Class ID: 73-77	3 or 4	Enterprise Replication events. See Enterprise Replication Event Alarms.	
Class ID: 78 Event ID: 78001	3	Class message: The storage pool is empty. Specific message: Warning: The storage pool is out of space.	
Class ID: 79 Event ID: 79001	3	Class message: Dynamically added chunk *chunk_name* to space Specific message: Dynamically added chunk *chunk_name* to space '*space_name*' Path: *path*, offset *offset_number* kilobytes Size: *size* kilobytes	
Class ID: 80 80001	2	Class message: A new fragment for table *table_name* has been added in DBspace *dbspace_name*.	A new fragment was automatically added to a table because the table grew larger than the size of its existing fragments. **Online log:** Message providing the table name and dbspace name. **Server state:** Online. **User action:** None.
Class ID: 81 Event ID: 81001	4	Class message: Logical log file or dbspace corruption detected during backup. Loguniq or Dbspace id: *ID*. Specific message: Log Backup detected a corrupted logical log file. Expected loguniq:pagenum *log_number*:*page_number* Actual loguniq:pagenum *log_number*:*page_number* Log backup continuing but the log backup cannot be used to restore a server. You should run **oncheck** and take a level 0 archive.	A backup failed because the database server detected corruption in the logical log file or dbspace. **Online log:** Assertion warning. **Server state:** Online. **User action:** Perform a new level-0 backup.
Class ID: 82 Event ID: 82001	3	Class message: session *ID* (*thread*) network write operation has been blocked for at least 30 minutes, which might indicate an operating system problem Specific message: session *ID* (*thread*) network write operation has been blocked for at least 30 minutes, which might indicate an operating system problem	
Class ID: 83 Event ID: 83001	3	Class message: SDS: Failover aborted - detected primary server is still active. Specific message: SDS: Failover aborted - detected primary server is still active.	

ID	Severity	Messages	Explanation
Event ID: 84001	3	Class message: Generic network failure alarm Specific message: Unable to bind to the port (port number or service name) on the host (IP address or host name) for the server (*dbservername*).	The host name or IP address, the service name, or the port number might be incorrect. The port might already be in use. **Server state:** Online, during server startup. **Online log:** Assertion warning. **User action:** Check the host name or IP address, the service name, and the port number entries in the sqlhosts file. Make that sure that the port is not already in use. Make the necessary changes and restart the server.
Event ID: 86001	3	Class message: Space has reached its maximum configured size. Specific msg: Warning: Space *space_name* has reached its maximum configured size (*size* MB).	The extendable storage space is at the configured maximum size and cannot expand further. **Server state:** Online **Online log:** **User action:** No action needed. If you want to increase the maximum size of the storage space, run the **admin()** or **task()** SQL administration API function with the modify space sp_sizes argument and specify a new maximum size.
Event ID: 87001	3	Message: **ifxguard** utility connected	The **ifxguard** agent connected to the database server. **Server state:** Online **Online log:** Message that identifies the agent name. **User action:** No action needed.
Event ID: 87002	3	Message: **ifxguard** utility disconnected	The **ifxguard** agent closed the connected to the database server. **Server state:** Online **Online log:** Message that identifies the agent name. **User action:** No action needed. The user session that the agent audited ended.
Event ID: 87003	3	Message: **ifxguard** utility has not responded	The **ifxguard** agent did not connect to the database server during the timeout period. **Server state:** Depends on the action set by the IFXGUARD configuration parameter. **Online log:** Message that identifies the agent name. **User action:** No action needed unless the database server shut down. If the database server shut down, examine the ifxguard log file to discover why the **ifxguard** agent failed to connect in time.

- Severity 5 event alarms
  Severity 5 event alarms indicate that the database server has failed.

Severity 5 event alarms

Severity 5 event alarms indicate that the database server has failed.

Table 1. Severity 5 event alarms

ID	Messages	Explanation
Class ID: 6 Event ID: 6033	Class message: Internal subsystem failure: *'message'* Specific message: Cache read error	The database server shut down after encountering an error while reading an internal cache. **Online log:** Assertion Failure. **Server State:** Offline. **User action:** Start the database server and try the operation again. If the operation fails again, note all circumstances and contact Software Support.

ID	Messages	Explanation
Class ID: 6 Event ID: 6041	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was detected by the Buffer Manager in the database server.	The database server buffer manager encountered an internal error and either shut down or corrected the problem. **Online log:** Assertion warning or an assertion failure with a description of the operation being performed at the time of the error. Typically, an assertion warning shows that the error was internally corrected. **Server State:** Offline if the error was unrecoverable. Online if the error was corrected. **User action:** If the error was unrecoverable, start the database server and try the operation again. If the operation fails again, note all circumstances and contact Software Support. No action is required if the error was internally corrected by the database server.
Class ID: 6 Event ID: 6042	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was reported by the database server when it detected an inconsistency with the internal buffer queues.	The database server detected an inconsistency during the processing of internal buffer queues and either shut down or corrected the problem. **Online log:** Assertion warning or an assertion failure with a description of the operation being performed at the time of the error. Typically, an assertion warning shows that the error was internally corrected. **Server State:** Offline if the error was unrecoverable. Online if the error was corrected. **User action:** If the error was unrecoverable, start the database server and try the operation again. If the operation fails again, note all circumstances and contact Software Support. No action is required if the error was internally corrected by the database server.
Class ID: 6 Event ID: 6045	Class message: Internal subsystem failure: *'message'* Specific message: Logical logging error for '*object*' in *'space'*	The database server shut down because of an error while processing logical logs. **Online log:** Assertion failure with a description of the operation and logical log information. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6049	Class message: Internal subsystem failure: *'message'* Specific message: Lock types *lock_type* and *lock_type* should never be merged	The database server shut down after attempting to merge incompatible locks. **Online log:** Assertion failure with the lock types that the database server was attempting to merge. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6050	Class message: Internal subsystem failure: *'message'* Specific message: An internal error was reported by the database server when it detected some corruption in the lock free list chain.	The database server shut down after detecting corruption of an internal structure that manages an internal list of free locks. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6060	Class message: Internal subsystem failure: *'message'* Specific message: Thread exited with *number* buffers held	The database server shut down after detecting that a thread is holding one or more buffers. **Online log:** Assertion failure with the number of buffers being held by the thread. **Server State:** Offline. **User action:** Bring the database server online. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6067	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (Recursive exception) has caused the database server processes to terminate unexpectedly.	The database server detected recursive calls to exception handling and immediately shut down to avoid an infinite loop. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.

ID	Messages	Explanation
Class ID: 6 Event ID: 6068	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (Internal exception) has caused the database server processes to terminate unexpectedly.	The database server shut down due to an unrecoverable internal error. **Online log:** Assertion failure with information about the exception that caused the problem. **Server State:** Offline. **User action:** Start the database server. Look at the exception information in the assertion failure file. If the exception relates to a user-defined routine, investigate and correct the user-defined routine. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6069	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (Master daemon died) has caused the database server processes to terminate unexpectedly.	The master daemon **oninit** process stopped and the database server shut down. This error can be caused by the termination of operating system processes. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. Be careful when terminating operating system processes.
Class ID: 6 Event ID: 6070	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (VP died) has caused the database server processes to terminate unexpectedly.	An **oninit** process stopped and the database server shut down. This error can be caused by the termination of operating system processes. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. Be careful when terminating operating system processes.
Class ID: 6 Event ID: 6071	Class message: Internal subsystem failure: *'message'* Specific message: ERROR: cannot fork secondary Server thread (MACH11 Shutdown)	The secondary server shut down but was unable to create a thread to shut down normally. **Online log:** `DR: Shutting down the server. ERROR: can not fork secondary Server thread (MACH11 Shutdown) Can not run onmode -ky PANIC: Attempting to bring system down.` **Server State:** Offline. **User action:** None.
Class ID: 6 Event ID: 6075	Class message: Internal subsystem failure: *'message'* Specific message: A fatal internal error (KAIO) has caused the database server processes to terminate unexpectedly.	The database server shut down because of an error in the KAIO subsystem. **Online log:** Assertion failure with the specific operation that failed. **Server State:** Offline. **User action:** Start the database server. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 6 Event ID: 6500	Generic event for when the database server terminates unexpectedly due to an internal error condition.	An internal error occurred and the database server shut down. **Online log:** Assertion failure. **Server State:** Offline. **User action:** Start the database server. Examine the assertion failure file for more information about what happened. If possible, fix any problems identified and try the operation again. If the operation fails again, note all circumstances and contact Software Support.
Class ID: 21 Event ID: 21004	Class message: Database server resource overflow: *'resource_name'* Specific message: Physical log file overflow	The physical log file is full and needs to overflow. If this happens during recovery, the database server attempts to extend the physical log. **Online log:** Assertion failure if the database server is either not in recovery or is unable to extend the physical log. Assertion warning if the database server is in recovery and extends the physical log. **Server State:** Offline. **User action:** None.
Class ID: 21 Event ID: 21006	Class message: Database server resource overflow: *'resource_name'* Specific message: Logical log buffer overflow detected	The database server shut down because the logical log buffer is full. **Online log:** Assertion failure with the log record size and the buffer size. **Server State:** Offline. **User action:** Increase the value of the LOGBUFF configuration parameter in the onconfig file. Start the database server.

Connection Manager event alarm IDs

The class ID for event alarms indicates the type of event. The event ID indicates the specific event.

The following table lists event alarm IDs and messages for the Connection Manager.

You can set your alarm program script to capture the Connection Manager class ID and message and initiate corrective actions or notifications.

You can use the values set in the INFORMIXCMNAME and INFORMIXCMCONUNITNAME environment variables when writing an alarm handler for the Connection Manager. If the Connection Manager raises an event alarm, the Connection Manager instance name is stored in the INFORMIXCMNAME environment variable, and the Connection Manager connection unit name is stored in the INFORMIXCMCONUNITNAME environment variable.

Event alarm messages are written to the Connection Manager log file.

Table 1. Connection Manager event alarms

ID	Severity	Messages	Explanation
Class ID: 1 Event ID: 1001	3	Class message: Connection Manager generic alarm Specific message: Connection Manager stopped	The Connection Manager stopped running. **Online log message:** Connection Manager shut down successfully. **User action:** Restart the Connection Manager, if necessary.
Class ID: 1 Event ID: 1002	3	Class message: Connection Manager generic alarm Specific message: Connection Manager fatal error	The Connection Manager failed to initialize. **Online log message:** Failed to switch to daemon mode, Connection Manager stopped. Error: Initialize failed, Connection Manager stopped. Error: SLA listener failed, Connection Manager can not start. **User action:** Check the message file for failure details. Correct any errors and then restart the Connection Manager.
Class ID: 1 Event ID: 1003	3	Class message: Connection Manager generic alarm Specific message: Connection Manager received signal	The Connection Manager stopped or crashed. **Online log message:** Connection Manager process received signal, shutting down **User action:** If the Connection Manager was killed by signal 9, no action is required. Otherwise, report the problem to the System Administrator.
Class ID: 2 Event ID: 2001	3	Class message: Failover Arbitrator alarm Specific message: Failover in progress	The Connection Manager Failover Arbitrator initiated a failover event. **Online log message:** Failover Arbitrator automated failover in progress.
Class ID: 2 Event ID: 2002	3	Class message: Failover Arbitrator alarm Specific message: Failover completed	The Connection Manager Failover Arbitrator has completed failover. **Online log message:** Failover Arbitrator automated failover completed.
Class ID: 2 Event ID: 2003	3	Class message: Failover Arbitrator alarm Specific message: Failover disabled	Automated failover for the Connection Manager is disabled. **Online log message:** Failover Arbitrator automated failover is disabled. **User action:** N/A
Class ID: 2 Event ID: 2004	3	Class message: Failover Arbitrator alarm Specific message: Failover Arbitrator aborting automated failover	Failover processing has failed. **Online log message:** Failover Arbitrator aborting automated failover. **User action:** Check the message log file, and then manually start the primary server or manually perform failover.
Class ID: 2 Event ID: 2005	3	Class message: Failover Arbitrator alarm Specific message: Failover processing is in manual mode	Failover processing is not in automatic mode. **Online log message:** Failover processing is in manual mode
Class ID: 3 Event ID: 3001	3	Class message: Connection to the primary Specific message: Cannot connect to primary server	The Connection Manager cannot connect to the primary server. **Online log message:** Unable to connect to Informix® server. **User action:** Correct the setup problem. Connection Manager can then connect to the server automatically.
Class ID: 3 Event ID: 3002	3	Class message: Connection to the primary Specific message: Lost connection to primary server	The Connection Manager is disconnected from the primary server. **Online log message:** Detected lost connection to Informix server. **User action:** Correct the setup or network problem. The Connection Manager can then connect to the primary server automatically.

ID	Severity	Messages	Explanation
Class ID: 3 Event ID: 3003	4	Class message: Connection to the primary Specific message: CM detected multiple primary servers in the cluster	Connection Manager is connected to multiple primary servers. **Online log message:** Detected multiple primary servers in the cluster. **User action:** Correct the setup or network problem so that Connection Manager is connected to only one primary server.
Class ID: 4 Event ID: 4001	3	Class message: Connection to ER node Specific message: Cannot connect to ER node	The Connection Manager cannot connect to an Enterprise Replication server. **User action:** Correct the setup problem. The Connection Manager can then connect to the Enterprise Replication server automatically.
Class ID: 4 Event ID: 4002	3	Class message: Connection to ER node Specific message: Lost connection to ER node	The Connection Manager has disconnected from an Enterprise Replication server. **Online log message:** Detected lost connection to Informix server **User action:** Correct the setup or network problem. The Connection Manager can then connect to the Enterprise Replication server automatically.
Class ID: 5 Event ID: 5001	3	Class message: Connection to generic server Specific message: Cannot connect to server	The Connection Manager cannot connect to a server in a high-availability cluster. **Online log message:** Unable to connect to Informix server. **User action:** Correct the setup problem. Connection Manager can then connect to the high-availability server automatically.
Class ID: 5 Event ID: 5002	3	Class message: Connection to generic server Specific message: Lost connection to server	The Connection Manager is disconnected from a secondary server. **Online log message:** Detected lost connection to Informix server. **User action:** Correct the setup or network problem. Connection Manager can then connect to the secondary server automatically.

Messages in the database server log

Unnumbered messages are printed in the database server message log (online.log). The error messages include corrective actions.

For a description of an error message, use the **finderr** utility or go to Error messages.

Some of the messages might require you to contact Software Support.

- How the Messages Are Ordered in This Chapter
- Messages: A-B
- Messages: C
- Messages: D-E-F
- Messages: G-H-I
- Messages: J-K-L-M
- Messages: N-O-P
- Messages: Q-R-S
- Messages: T-U-V
- Messages: W-X-Y-Z
- Messages: Symbols
- Conversion and reversion error messages
  If conversion or reversion is not successful, error messages are stored in the online.log file to help you identify what failed and what actions to take to fix the problem.
- Conversion and Reversion Messages for Enterprise Replication
  During conversion and reversion, specific messages are logged for Enterprise Replication by the concdr, revcdr, and revtestcdr scripts.
- Dynamic Log Messages
- Sbspace Metadata Messages
- Truncate Table Messages

ON-Bar messages and return codes

How the Messages Are Ordered in This Chapter

Database server message-log messages are arranged in this chapter in alphabetical order, sorted with the following additional rules:

- The time stamp that precedes each message is ignored.
- Letter case is ignored in alphabetization.
- Spaces are ignored.
- Quotation marks are ignored.
- Leading ellipses are ignored.
- The word *the* is ignored if it is the first word in the message.
- Messages that begin with numbers or punctuation symbols appear toward the end of the list in a special section labeled Messages: Symbols.
- Certain related messages are grouped together, as follows:
  - Conversion and reversion error messages
  - Conversion and Reversion Messages for Enterprise Replication
  - Dynamic Log Messages
  - Sbspace Metadata Messages
  - Truncate Table Messages

A cause and suggested corrective action for a message or group of messages follow the message text.

- How to view these messages
- Message Categories

How to view these messages

Use one of the following methods to view these messages:

- Online message log
  To see the messages displayed as they occur, use the **tail -f** *online.log* command.
- **onstat -m** command
  For more information, see onstat -l command: Print physical and logical log information.

To see the error number associated with these unnumbered messages, view the **logmessage** table in the **sysmaster** database:

```
SELECT * FROM logmessage;
```

Message Categories

Four general categories of unnumbered messages exist, although some messages fall into more than one category:

- Routine information
- Assertion-failed messages
- Administrative action needed
- Unrecoverable error detected

Technical Support uses the assertion-failed messages to assist in troubleshooting and diagnostics. The information that they report often falls into the category of *unexpected events* that might or might not develop into problems caught by other error codes. Moreover, the messages are terse and often extremely technical. They might report on one or two isolated statistics without providing an overall picture of what is happening. This information can suggest to technical support possible research paths.

Messages: A-B

Aborting Long Transaction: *tx 0xn.*

Cause

The transaction spans the log space specified by transaction high-watermark (LTXHWM), and the offending long transaction is rolling back.

Action

No additional action is needed. The address of the transaction structure in shared memory is displayed as a hexadecimal value.

Affinitied VP *mm* to phys proc *nn*.

Cause

The database server successfully bound a CPU virtual processor to a physical processor.

Action

None required.

Affinity not enabled for this server.

Cause

You tried to bind your CPU virtual processors to physical processors, but the database server that you are running does not support process affinity.

Action

Remove the affinity setting from the VPCLASS configuration parameter.

Assert Failed: Error from SBSpace cleanup thread.

Cause

The sbspace cleanup thread encountered an error while cleaning up stray smart large objects.

Action

See the action suggested in the message log file.

Most of the time, running **onspaces -cl sbspacename** on the failed sbspace succeeds in cleaning up any stray smart large objects. If you encounter an unrecoverable error, contact Technical Support.

Assert Failed: Short description of what failed Who: Description of user/session/thread running at the time Result: State of the affected database server entity Action: What action the database administrator should take See Also: DUMPDIR/af.uniqid containing more diagnostics.

Cause

This message indicates an internal error.

Action

The **af.uniqid** file in the directory specified by the ONCONFIG parameter DUMPDIR contains a copy of the assertion-failure message that was sent to the message log, as well as the contents of the current, relevant structures and/or data buffers. The information included in this message is intended for Technical Support.

Begin re-creating indexes deferred during recovery.

Cause

During recovery, indexes to be created are deferred until after recovery completes. This message indicates that the database server deferred re-creating indexes and that it is now creating the indexes. During the time that the database server re-creates the indexes, it locks the affected tables with a shared lock.

Action

None required.

Building 'sysmaster' database requires ~*mm* pages of logical log. Currently there are *nn* pages available. Prepare to back up your logs soon.

Cause

You do not currently have the approximate amount of free log space necessary to complete a build of the sysmaster database.

Action

Back up your logs.

Building 'sysmaster' database...

Cause

The database server is building the **sysmaster** database.

Action

None required.

Messages: C

Cannot Allocate Physical-log File, *mm* wanted, *nn* available.

Cause

The database server attempted to increase the size of the physical log, but it needed more contiguous space than was available in the dbspace. The quantities of space are expressed as kilobytes.

Action

You must either specify a smaller size for the physical log (use the PHYSFILE configuration parameter), or change the location of the physical log to a dbspace that contains adequate contiguous space to accommodate the larger physical log.

Cannot alter a table which has associated violations table.

Cause

The user tried to add, drop, or modify a column in a table that has a violations table associated with it.

Action

Do not change the columns in the user table.

Cannot change to mode.

Cause

Some error during fast or full recovery has prevented the system from changing to online or quiescent mode.

Action

See previous messages in the log file for information.

Cannot Commit Partially Complete Transactions.

Cause

Transactions that drop tables or indexes do not perform the drop until a COMMIT statement is processed (with a few exceptions). In these cases, a *beginning commit* log record is written, followed by the usual commit log record. If the database server fails in between the two, the fast recovery process attempts to complete the commit the next time that you initialize the database server.

If this completion of the commit fails, the database server generates the preceding message.

Action

To determine if you need to take action, examine the logical log as described in Interpreting Logical-Log Records.

Cannot create a user-defined VP class with 'SINGLE_CPU_VP' non-zero.

Cause

SINGLE_CPU_VP is set to nonzero, and **onmode** was used to create a user-defined VP class.

Action

If user-defined VP classes are necessary, stop the database server, change SINGLE_CPU_VP to zero, and restart the database server.

Cannot create violations/diagnostics table.

Cause

The user issued a START VIOLATIONS TABLE statement for a target table. The database server cannot create the violations table for this target table. Any of the following situations might be the reason for this failure:

- The target table already has a violations table.
- You specified an invalid name for the violations table in the START VIOLATIONS TABLE statement. For example, if you omit the USING clause from the statement and if the number of characters in the target table plus four characters is longer than the maximum identifier length, the generated names of the violations table exceed the maximum identifier length.
- You specified a name for the violations table in the START VIOLATIONS TABLE statement that match the names of existing tables in the database.
- The target table contains columns with the names **informix_tupleid**, **informix_optype**, or **informix_recowner**. Because these column names duplicate the **informix_tupleid**, **informix_optype**, or **informix_recowner** columns in the violations table, the database server cannot create the violations table.
- The target table is a temporary table.
- The target table is serving as a violations table for some other table.
- The target table is a system catalog table.

Action

To resolve this error, perform one of the following actions:

- If the violations table name was invalid, specify a unique name for the violations table in the USING clause of the START VIOLATIONS TABLE statement.
- If the target table contains columns with the names **informix_tupleid**, **informix_optype**, or **informix_recowner**, rename them to something else.
- Choose a permanent target table that is not a system catalog table or a violations table for some other table.

Cannot insert from the violations table to the target table.

Cause

The user has issued a statement that attempts to insert rows from the violations table into the target table. For example, the user enters the following invalid statement:

```
INSERT INTO mytable SELECT * FROM mytable_vio;
```

Also, if the target table has filtering-mode constraints, you receive this error.

Action

To recover from this error, perform the following actions:

- Do not use filtering constraints.
- Stop the violations table.
- Insert rows from the violations table into a temporary table, and then insert rows from the temporary table into the target table.

Cannot modify/drop a violations/diagnostics table.

Cause

The user has tried to alter or drop a table that is serving as a violations table for another table.

Action

Do not alter or drop the violations table.

Cannot Open Dbspace *nnn*.

Cause

The database server is unable to access the specified dbspace. This message indicates a problem opening the tblspace or corruption in the initial chunk of the dbspace.

Action

Verify that the device or devices that make up the chunks of this dbspace are functioning properly and that you assigned them the correct operating-system permissions (rw-rw----). You might be required to perform a data restore.

Cannot Open Logical Log.

Cause

The database server is unable to access the logical-log files. Because the database server cannot operate without access to the logical log, you must resolve this problem.

Action

Verify that the chunk device where the logical-log files reside is functioning and has the correct operating-system permissions (rw-rw----).

Cannot Open Mirror Chunk *pathname*, errorno = *nn*.

Cause

The database server cannot open the mirrored chunk of a mirrored pair. The chunk *pathname* and the operating-system error are returned.

Action

For more information about corrective actions, see your operating-system documentation.

Cannot Open Primary Chunk *pathname*, errorno = *nnn*.

Cause

The primary chunk of a mirrored pair cannot be opened. The chunk *pathname* and the operating-system error are returned.

Action

For more information about corrective actions, see your operating-system documentation.

Cannot Open Primary Chunk *chunkname*.

Cause

The *initial* chunk of the dbspace cannot be opened.

Action

Verify that the chunk device is running properly and has the correct operating-system permissions (rw-rw----).

Cannot open sysams in database *name*, iserrno *number*.

Cause

An error occurred when the database server opened the **sysams** system table.

Action

Note the error *number* and contact Technical Support.

Cannot open sysdistrib in database *name*, iserrno *number*.

Cause

An error occurred when the database server accessed the **sysdistrib** system table.

Action

Note the error *number* and contact Technical Support.

Cannot open *system_table* in database *name*, iserrno *number*.

Cause

An error occurred when the database server opened the specified system table.

Action

Note the error *number* and contact Technical Support.

Cannot open systrigbody in database *name*, iserrno *number*.

Cause

An error occurred when the database server accessed the **systrigbody** system table.

Action

Note the error *number* and contact Technical Support.

Cannot open systriggers in database *name*, iserrno *number*.

Cause

An error occurred when the database server accessed the **systriggers** system table.

Action

Note the error *number* and contact Technical Support.

Cannot open sysxtdtypes in database *name*, iserrno *number*.

Cause

An error occurred while accessing the **sysxtdtypes** system table.

Action

Note the error *number* and contact Technical Support.

Cannot Perform Checkpoint, shut system down.

Cause

A thread that is attempting to restore a mirrored chunk has requested a checkpoint, but the checkpoint cannot be performed.

Action

Shut down the database server.

Cannot Restore to Checkpoint.

Cause

The database server is unable to recover the physical log and thus unable to perform fast recovery.

Action

If the database server does not come online, perform a data restore from dbspace backup.

Cannot Rollback Incomplete Transactions.

Cause

Within the fast-recovery or data-restore procedure, the logical-log records are first rolled forward. Then, open transactions that have not committed are rolled back. An open transaction could fail during the rollback, leaving some of the modifications from the open transaction in place. This error does not prevent the database server from moving to quiescent or online mode, but it might indicate an inconsistent database.

Action

To determine if any action is needed, use the onlog utility to examine the logical log.

Cannot update pagezero.

Cause

A failure occurred while the database server was trying to rewrite a reserved page during the reversion process.

Action

See previous messages in the log file for information, or contact Technical Support.

Cannot update syscasts in database *name*. Iserrno *number*.

Cause

An internal error occurred while inserting data into the **syscasts** system table.

Action

Contact Technical Support..

Can’t affinity VP *mm* to phys proc *nn*.

Cause

The database server supports process affinity, but the system call to bind the virtual processor to a physical processor failed.

Action

See your operating-system documentation.

Changing the sbspace minimum extent value: old value *value1*, new value *value2*.

Cause

This informational message occurs when you issue the following command:

```
onspaces -ch sbspace -Df "MIN_EXT_SIZE=value1" -y
```

Action

None. For more information, see onspaces -ch: Change sbspace default specifications.

Checkpoint blocked by down space, waiting for override or shutdown.

Cause

A dbspace has gone down during a checkpoint interval. The database server is configured to wait for an override when this situation occurs.

Action

Either shut down the database server or issue an **onmode -O** command to override the down dbspace. For more information on the **onmode** utility, see The onmode utility.

Checkpoint Completed: duration was *n* seconds.

Cause

A checkpoint completed successfully.

Action

None required.

Checkpoint Page Write Error.

Cause

The database server detected an error in an attempt to write checkpoint information to disk.

Action

For additional assistance in resolving this situation, contact Technical Support.

Checkpoint Record Not Found in Logical Log.

Cause

The logical log or the chunk that contains the logical log is corrupted. The database server cannot initialize.

Action

Perform a data restore from dbspace backup.

Chunk *chunkname* added to space *spacename.*

Cause

The variables in this message have the following values:

chunkname
: is the name of the chunk that the database server administrator is adding.

spacename
: is the name of the storage space to which the database server administrator is adding the chunk.

Action

None required.

Chunk *chunkname* dropped from space *spacename.*

Cause

The database server administrator dropped chunk *chunkname* from space *spacename*.

Action

None required.

Chunk *number nn pathname* -- Offline.

Cause

The indicated chunk in a mirrored pair has been marked with status `D` and taken offline. The other chunk in the mirrored pair is operating successfully.

Action

Take steps now to repair the chunk device and restore the chunk. The chunk *number* and chunk device *pathname* are displayed.

Chunk *number nn pathname* -- Online.

Cause

The indicated chunk in a mirrored pair has been recovered and is online (marked with status `O`). The chunk *number* and chunk device *pathname* are displayed.

Action

None required.

The chunk *pathname* must have READ/WRITE permissions for owner and group.

Cause

The chunk *pathname*does not have the correct owner and group permissions.

Action

Make sure that you assigned the correct permissions (-rw-rw---) to the device on which the chunk is located.

The chunk *pathname* must have *owner-ID* and *group-ID* set to informix.

Cause

The chunk *chunkname* does not have the correct owner and group ID.

Action

Make sure the device on which the chunk is located has the ownership. On UNIX, both owner and group should be **informix**. On Windows, the owner must be a member of the **Informix-Admin** group.

The chunk *pathname* will not fit in the space specified.

Cause

The chunk *pathname* does not fit in the space that you specified.

Action

Choose a smaller size for the chunk, or free space where the chunk is to be created.

Cleaning stray LOs in sbspace *sbspacename*.

Cause

The database server administrator is running **onspaces -cl sbspacename**.

Action

None required.

Completed re-creating indexes.

Cause

The database server finished re-creating the deferred indexes.

Action

None required.

Configuration has been grown to handle up to *integer* chunks.

Cause

The database server administrator increased the number of chunks to the specified value by changing CONFIGSIZE or setting MAX_CHUNKS to a higher value.

Action

None required. The change was successful.

Configuration has been grown to handle up to *integer* dbslices.

Cause

The database server administrator increased the number of dbslices to the specified value by changing CONFIGSIZE or setting MAX_DBSLICES to a higher value.

Action

None required. The change was successful.

Configuration has been grown to handle up to *integer* dbspaces.

Cause

The database server administrator increased the number of dbspaces to the specified value by changing CONFIGSIZE or setting MAX_DBSPACES to a higher value.

Action

None required. The change was successful.

Continuing Long Transaction (for COMMIT): *tx 0xn*.

Cause

The logical log has filled beyond the long-transaction high-watermark (LTXHWM), but the offending long transaction is in the process of committing. In this case, the transaction is permitted to continue writing to the logical log and is not rolled back. The address of the transaction structure in shared memory is displayed as hexadecimal value *tx 0xn*.

Action

None required.

Could not disable priority aging: errno = *number*.

Cause

An operating-system call failed while it was trying to disable priority aging for the CPU virtual processor. The system error *number* associated with the failure is returned.

Action

See your operating-system documentation.

Could not fork a virtual processor: errno = *number*.

Cause

The fork of a virtual processor failed. The database server returns the operating-system error *number* associated with the failure.

Action

For information on determining the maximum number of processes available per user and for the system as a whole, refer to your operating-system documentation.

Create_vp: cannot allocate memory.

Cause

The database server cannot allocate new shared memory.

Action

The database server administrator must make more shared memory available. This situation might require increasing SHMTOTAL or reconfiguring the operating system. This message is usually accompanied by other messages that give additional information.

Messages: D-E-F

Dataskip is OFF for all dbspaces.

Cause

Informational.

Action

None required.

Dataskip is ON for all dbspaces.

Cause

Informational.

Action

None required.

Dataskip is ON for dbspaces: *dbspacelist*.

Cause

Informational; DATASKIP is ON for the specified dbspaces.

Action

None required.

Dataskip will be turned {ON|OFF} for *dbspacename*.

Cause

Informational; DATASKIP is ON or OFF for the specified dbspace.

Action

None required.

DBSERVERALIASES exceeded the maximum limit of 32

Cause

The limit of 32 aliases was reached.

Action

Nothing. Only the first 32 will be used.

DBSPACETEMP internal list not initialized, using default.

Cause

An error occurred while initializing a user-specified DBSPACETEMP list. Typically this condition is due to a memory-allocation failure.

Action

Check for accompanying error messages.

The DBspace/BLOBspace *spacename* is now mirrored.

Cause

You successfully added mirroring to the indicated storage space.

Action

None required.

The DBspace/BLOBspace *spacename* is no longer mirrored.

Cause

You have ended mirroring for the indicated storage space.

Action

None required.

devname: write failed, file system is full.

Cause

Because the file system *devname* is full, the write failed.

Action

Free some space in *devname*.

Dropping temporary tblspace *0xn*, recovering *nn* pages.

Cause

During shared-memory initialization, the database server routinely searches for temporary tables that are left without proper cleanup. If the database server finds a temporary table, it drops the table and recovers the space. The database server located the specified temporary tblspace and dropped it. The value *0xn* is the hexadecimal representation of the tblspace number.

Action

None required.

Dynamically allocated new shared memory segment (size *nnnn*).

Cause

This status message informs you that the database server successfully allocated a new shared-memory segment of size *nnnn*.

Action

None required.

ERROR: NO "wait for" locks in Critical Section.

Cause

The database server does not permit a thread to own locks that might have to wait while that thread is within a critical section. Any such lock request is denied, and an ISAM error message is returned to the user.

Action

The error reported is an internal error. Contact IBM® Informix® Technical Support.

Error building sysmaster database. See *outfile*.

Cause

Errors were encountered in building the sysmaster database. The file *outfile* contains the result of running the script buildsmi.

Action

See the file *outfile*.

Error in dropping system defined type.

Cause

An internal error occurred while updating either the **sysxtdtypes**, **sysctddesc**, or **sysxtdtypeauth** system table.

Action

Contact Technical Support.

Error in renaming systdist.

Cause

An internal error occurred while trying to find and rename the **Informix®.systdist** SPL routine.

Action

Contact Technical Support.

Error removing sysdistrib row for tabid = *tabid*, colid = *colid* in database *name*. iserrno = *number*

Cause

An error occurred while updating the **sysdistrib** system table.

Action

Note the error *number* and contact Technical Support.

Error writing *pathname* errno = *number*.

Cause

The operating system cannot write to *pathname. Number* is the number of the operating-system error that was returned.

Action

Investigate the cause of the operating-system error. Usually it means that no space is available for the file. It might also mean that the directory does not exist or that no write permissions exist.

Error writing shmem to file *filename* (*error*). Unable to create output file *filename* errno=*mm*.Error writing *filename* errno=*nn*.

Cause

The database server detected an error in an attempt to write shared memory to *filename*. The first message is followed by one of the next two. Either the attempt failed because the output file could not be created or because the contents of shared memory could not be written. The error refers to the operating-system error that prompted the attempted write of shared memory to a file. The value of *nn* is the operating-system error.

Action

See your operating-system documentation.

Fail to extend physical log space.

Cause

The attempt to extend the physical log space failed. Either the path does not exist or the permissions are incorrect.

Action

Use a path that exists. Check permissions on the current working directory. You or the system administrator must give your group execute permission on the current working directory. After your group has been given permission, retry the operation that generated this message.

Fatal error initializing CWD string. Check permissions on current working directory. Group *groupname* must have at least execute permission on '.'.

Cause

Group *groupname* does not have execute permission for the current working directory.

Action

Check permissions on the current working directory. You or the system administrator must give your group execute permission on the current working directory. After your group has been given permission, retry the operation that generated this message.

Fragments *dbspacename1 dbspacename2* of table *tablename* set to non-resident.

Cause

The specified fragments of *tablename* either have been set to nonresident by the SET TABLE statement.

Action

None required.

Forced-resident shared memory not available.

Cause

The database server port for your computer does not support forced-resident shared memory.

Action

None required.

Freed *mm* shared-memory segment(s) *number* bytes.

Cause

The database server sends this message to the message log after you run the **-F** option of the **onmode** utility to free unused memory. The message informs you of the number of segments and bytes that the database server successfully freed.

Action

None required.

Messages: G-H-I

gcore *pid*; mv core.*pid* dir/core.*pid*.ABORT.

Cause

This status message during a database server failure provides the name and place of each core file associated with the virtual processors.

Action

None required.

I/O *function* chunk *mm*, pagenum *nn*, pagecnt *aa* --> errno = *bb*.

Cause

An operating-system error occurred during an attempt to access data from disk space. The operating-system function that failed is defined by *function*. The chunk number and physical address of the page where the error occurred are displayed as integers. The *pagecnt* value refers to the number of pages that the thread was attempting to read or write. If an *errno* value is displayed, it is the number of the operating-system error and might explain the failure. If *function* is specified as *bad request*, some unexpected event caused the I/O attempt on an invalid chunk or page.

Action

If the chunk status changes to `D`, or down, restore the chunk from its mirror or repair the chunk. Otherwise, perform a data restore.

I/O error, *primary/mirror* Chunk *pathname* -- Offline (*sanity*).

Cause

The database server detected an I/O error on a primary or mirror chunk with *pathname*. The chunk was taken offline.

Action

Check that the device on which the chunk was stored is functioning as intended.

Deleted Indexes idx1 and idx 2 error message

Informix® *database_server* Initialized - Complete Disk Initialized.

Cause

Disk space and shared memory have been initialized. Any databases that existed on the disk before the initialization are now inaccessible.

Action

None required.

Informix® *database_server* Initialized - Shared Memory Initialized.

Cause

Shared memory has been initialized.

Action

None required.

Informix® *database_server* Stopped.

Cause

The database server has moved from quiescent mode to offline mode. The database server is offline.

Action

None required.

In-Place Alter Table. Perform EXECUTE FUNCTION sysadmin:task('table update_ipa', 'table_name','database');

Cause

Reversion to a previous version of the database server was attempted while an in-place alter operation is in progress on a table. The previous versions of the database server cannot handle tables that have multiple schemas of rows in them.

Action

Force any in-place alter operations to complete by updating the rows in the affected tables before you attempt to revert to a previous version of the database server. Run the SQL administration API **task()** or **admin()** command with the **table update_ipa** argument to resolve all pending in-place alter operations on the table.

ERROR: Insufficient available disk in the root dbspace to increase the entire Configuration save area.

Cause

The user attempted to increase the number of storage objects to a specific value by changing CONFIGSIZE or setting MAX_DBSPACES, MAX_DBSLICES, or MAX_CHUNKS to a higher value, but the database server did not have enough rootspace for the increased number of storage objects. A storage object might be a dbspace, dbslice, or chunk.

Action

Increase the size of the root dbspace or reset CONFIGSIZE, MAX_DBSPACES, MAX_DBSLICES, or MAX_DBSLICES to a lower value and restart the database server. For example, if you set MAX_CHUNKS to `32,768`, but the root dbspace did not have enough space, set MAX_CHUNKS to a lower value.

Insufficient available disk in the root dbspace for the CM save area. Increase the size of the root dbspace in the ONCONFIG file and reinitialize the server.

Cause

The cause might be one of the following:

- The user attempted to increase the number of storage objects to a specific value by changing CONFIGSIZE or setting MAX_DBSPACES, MAX_DBSLICES, or MAX_CHUNKS to a higher value, but the database server did not have enough rootspace for the increased number of storage objects. A storage object might be a dbspace, dbslice, or chunk.
- The user converted to a database server version that requires slightly more rootspace, but it is not available (this case is unlikely).

Action

Take one of the following actions:

- Increase the size of the root dbspace or reset CONFIGSIZE, MAX_DBSPACES, MAX_DBSLICES, or MAX_DBSLICES to a lower value and restart the database server. For example, if you set MAX_DBSPACES to `32,768` but the root dbspace did not have enough space, set MAX_DBSPACES to a lower value.
- Increase the size of the root dbspace and reinitialize the database server.

Internal overflow of shmid's, increase system max shared memory segment size.

Cause

The database server was initializing shared memory when it ran out of internal storage for the shared-memory IDs associated with this segment.

Action

Increase the value of your maximum kernel shared-memory segment size, usually SHMMAX. For more information, see your operating-system documentation.

Messages: J-K-L-M

- Logical Recovery Started.
- Maximum server connections number.
- Memory allocation error.
- Mirror Chunk chunkname added to space spacename. Perform manual recovery.
- Mixed transaction result. (pid=nn user=userid).
- mt_shm_free_pool: pool 0xn has blocks still used (id nn).
- mt_shm_init: can't create resident/virtual segment.
- mt_shm_remove: WARNING: may not have removed all/correct segments.

Listener-thread err = *error_number*: *error_message.*

Cause

A listener thread has encountered an error. This message displays the error number and message text.

Action

For a description of an error message, use the **finderr** utility or go to Error messages.

Lock table overflow - user id *mm* session id *nn.*

Cause

A thread attempted to acquire a lock when no locks were available. The user ID and session ID are displayed.

Action

Increase the LOCKS configuration parameter, and initialize shared memory.

Logical-log File not found.

Cause

The checkpoint record in the root dbspace reserved page is corrupted.

Action

Perform a data restore from dbspace backup.

Logical Log *nn* Complete.

Cause

The logical-log file identified by log-ID number *nn* is full. The database server automatically switches to the next logical-log file in the sequence.

Action

None required.

Logical logging *vberror* for *type:subtype* in (*failed_system*).

Cause

Logging failed. The log record that caused the error is identified as follows:

type
: Is the logical-log record type.

subtype
: Is the logging subsystem.

failed_system
: Is the name of an internal function that indicates what system failed to log.

Action

Contact Technical Support.

Log Record: log = *ll*, pos = *0xn*, type = *type:subtype(snum),* trans = *xx*

Cause

The database server detected an error during the rollforward portion of fast recovery or logical-log restore.

The log record that caused the error is identified as follows:

ll
: Is the logical-log ID where the record is stored.

0xn
: Is the hexadecimal address position within the log.

type
: Is the logical-log record type.

subtype
: Is the logging subsystem.

snum
: Is the subsystem number.

xx
: Is the transaction number that appears in the logical log.

Action

Contact Technical Support.

Log record (*type:subtype*) at log *nn*, *0xn* was not undone.

Cause

A log undo failed because a log is corrupt.

The log record that caused the error is identified as follows:

type
: Is the logical-log record type.

subtype
: Is the logging subsystem.

nn
: Is the logical-log ID where the record is stored.

0xn
: Is the hexadecimal address position within the log.

Action

To determine if any action is needed, use the onlog utility to examine the logical log. Contact Technical Support.

Log record (*type:subtype*) failed, partnum *pnum row rid* iserrno *num*.

Cause

A logging failure occurred.

The log record that caused the error is identified as follows:

type
: Is the logical-log record type.

subtype
: Is the logging subsystem.

pnum
: Is the part number.

rid
: Is the row ID.

num
: Is the iserror number.

Action

Contact Technical Support.

Log record (*type:subtype*) in log *nn*, offset *0xn* was not rolled back.

Cause

A log undo failed because a log is corrupt.

The log record that caused the error is identified as follows:

type
: Is the logical-log record type.

subtype
: Is the logging subsystem.

log
: Is the logical-log ID where the record is stored.

offset
: Is the hexadecimal address position within the log.

Action

To determine if any action is needed, use the onlog utility to examine the logical log. Contact Technical Support.

Logical Recovery allocating *nn* worker threads *thread_type*.

Cause

The database server determined the number of worker threads that will be used for parallel recovery. The variable *thread_type* can assume the values ON_RECVRY_THREADS or OFF_RECVRY_THREADS.

Action

This status message requires no action. If you want a different number of worker threads allocated for parallel recovery, change the value of the ONCONFIG configuration parameter ON_RECVRY_THREADS or OFF_RECVRY_THREADS.

Logical Recovery Started.

Cause

Logical recovery began.

Action

This status message requires no action.

Maximum server connections *number*.

Cause

Outputs with each checkpoint message to indicate the maximum number of concurrent connections to the database server since the last restart.

Action

This message helps the customer track license usage to determine when more licenses need to be purchased. For assistance, Contact Technical Support.

Memory allocation error.

Cause

The database server ran out of shared memory.

Action

Take one of the following actions:

1. Increase swap space on the computer.
2. Check kernel shared-memory parameters for limits on shared memory.
3. Decrease the size of the memory allocated, with the **buffers** field in the BUFFERPOOL configuration parameter.
4. Increase the virtual-memory size (SHMVIRTSIZE), the size of the added segments, (SHMADD), or your total shared-memory size (SHMTOTAL).

Mirror Chunk *chunkname* added to space *spacename*. Perform manual recovery.

Cause

Fast recovery, full recovery, or an HDR secondary has recovered the add of a mirror chunk. It does not perform automatic mirror recovery, however. The administrator must do this.

Action

Use the **onspaces** utility to attempt to recover the mirror chunks.

Mixed transaction result. (*pid=nn* user=*userid*).

Cause

You receive this message only when more than one database server is involved in a transaction. This message indicates that a database server, after preparing a transaction for commit, heuristically rolled back the transaction, and the global transaction completed inconsistently. The *pid* value is the user-process identification number of the coordinator process. The value of *user* is the user ID associated with the coordinator process.

Action

See the information on recovering manually from failed two-phase commit in your *IBM® Informix® Administrator's Guide*.

mt_shm_free_pool: pool *0xn* has blocks still used (id *nn*).

Cause

An internal error occurred during a pool deallocation because blocks are still associated with the pool.

Action

Contact Technical Support.

mt_shm_init: can't create *resident/virtual* segment.

Cause

The causes for the failure to create the resident or virtual segment are as follows: (1) the segment size is less than the minimum segment size; (2) the segment size is larger than the maximum segment size; (3) allocating another segment would exceed the allowable total shared-memory size; or (4) a failure occurred while the database server was trying to allocate the segment.

Action

If you suspect that this error was generated because of item 1 or 2 in the preceding paragraph, Contact Technical Support. To correct item 3, increase the SHMTOTAL value in your ONCONFIG configuration file. For additional information about errors generated because of item 4, see your logical-log file.

mt_shm_remove: WARNING: may not have removed all/correct segments.

Cause

When the operating system tried to remove the shared-memory segments associated with the database server, the last segment did not equal the last segment registered internally. This situation is probably due to the unexpected failure of the database server.

Action

Remove any segments that were not cleaned up.

Messages: N-O-P

- Physical recovery started at page (chunk:offset).
- Portions of partition partnum of table tablename in database dbname were not logged. This partition cannot be rolled forward.
- Possible mixed transaction result.
- Prepared participant site server_name did not respond.
- Prepared participant site server_name not responding.

Newly specified value of *value* for the pagesize in the configuration file does not match older value of *value*. Using the older value.

Cause

This message displays upon database server restart. The PAGESIZE value changed in the ONCONFIG file after the database server was initialized.

Action

The database server uses the older PAGESIZE value.

Not enough main memory.

Cause

The database server detected an error in an attempt to acquire more memory space from the operating system.

Action

For more information about shared-memory configuration and management, refer to your operating-system documentation.

Not enough logical-log files, Increase LOGFILES.

Cause

During a data restore, the value of the LOGFILES configuration must always be greater than or equal to the total number of logical-log files. At some point during the restore, the number of logical-log files exceeded the value of LOGFILES.

Action

Increase the value of LOGFILES in ONCONFIG.

The number of configured inline poll threads exceeds the number of CPU virtual processors.

Cause

This message is generated when the number of inline poll threads specified by the NETTYPE configuration parameter exceeds the number of CPU virtual processors configured by the VPCLASS configuration parameter. Poll threads that are configured to run on CPU virtual processors are referred to as inline poll threads.

Action

Either modify the VPCLASS configuration parameter to increase the number of CPU virtual processors, or modify the NETTYPE configuration parameter to decrease the number of inline poll threads.

Related reference:
NETTYPE configuration parameter
VPCLASS configuration parameter

onconfig parameter *parameter* modified from *old_value* to *new_value.*

Cause

When the database server shared memory is reinitialized, this message documents any changes that occurred since the last initialization.

Action

None required.

oninit: Cannot have SINGLE_CPU_VP non-zero and number of CPU VPs greater than 1.

Cause

The ONCONFIG file contains VPCLASS cpu with a `num=` value greater than `1` and a nonzero value for SINGLE_CPU_VP. SINGLE_CPU_VP must be 0 (or omitted) when there are more than 1 CPU VPs.

Action

Correct the ONCONFIG file and restart the database server.

oninit: Cannot have SINGLE_CPU_VP non-zero and user-defined VP classes.

Cause

The ONCONFIG file contains a user-defined VPCLASS as well as a nonzero value for SINGLE_CPU_VP. SINGLE_CPU_VP must be `0` (or omitted) when the ONCONFIG file contains a user-defined VPCLASS.

Action

Correct the ONCONFIG file and restart the database server.

oninit: Fatal error in initializing ASF with 'ASF_INIT_DATA' flags asfcode = '25507'.

Cause

The **nettype** value specified in the **sqlhosts** file or registry for the database server is invalid or unsupported, or the **servicename** specified in the **sqlhosts** file or registry for the database server is invalid.

Action

Check the **nettype** and **servicename** values in the **sqlhosts** file or registry for each DBSERVERNAME and for the DBSERVERALIASES. Check the **nettype** value in each NETTYPE parameter in the ONCONFIG file.

Cannot alter a table which has associated violations table.

Cause

The user tried to add, drop, or modify a column in a table that has a violations table associated with it.

Action

Do not change the columns in the user table.

oninit: Too many VPCLASS parameters specified.

Cause

Too many VPCLASS parameter lines have been specified in the ONCONFIG file.

Action

Reduce the number of VPCLASS lines, if possible. If not possible, contact Technical Support.

oninit: VPCLASS *classname* bad affinity specification.

Cause

The affinity specification for the VPCLASS line is incorrect. Affinity is specified as a range:

For *m,* use processor *m*.

For *m* to *n,* use processors in the range *m* to *n* inclusive, where *m* <=*n*, *m* >= 0, and *n* >= 0.

Action

Correct the VPCLASS parameter in the ONCONFIG file and restart the database server.

oninit: VPCLASS *classname* duplicate class *name*.

Cause

The VPCLASS *classname* in the ONCONFIG file has a duplicate name. VP class names must be unique.

Action

Correct the duplicate name and restart the database server.

oninit: VPCLASS *classname* illegal option.

Cause

One of the fields in the VPCLASS *classname* parameter is illegal.

Action

Correct the parameter in the ONCONFIG file and restart the database server.

oninit: VPCLASS *classname* maximum number of VPs is out of the range 0-10000.

Cause

The maximum number of VPs specified by a VPCLASS parameter line must be in the range 1 to 10,000.

Action

Correct the value and restart the database server.

oninit: VPCLASS *classname* name is too long. Maximum length is *maxlength*.

Cause

The length of the name field in VPCLASS *classname* is too long.

Action

Choose a shorter class name, correct the ONCONFIG file, and restart the database server.

oninit: VPCLASS *classname* number of VPs is greater than the maximum specified.

Cause

The initial number of VPs specified by a VPCLASS parameter is greater than the maximum specified by the same VPCLASS parameter.

Action

Correct the VPCLASS parameter and restart the database server.

oninit: VPCLASS *classname* number of VPs is out of the range 0-10000.

Cause

The initial number of VPs specified by a VPCLASS parameter line must be in the range 1 to 10,000.

Action

Correct the value and restart the database server.

onmode: VPCLASS *classname* name is too long. Maximum length is *maxlength*.

Cause

The name of a dynamically added VP class that **onmode -p** specifies is too long.

Action

Choose a shorter name, and retry the **onmode -p** command.

Online Mode.

Cause

The database server is in online mode. Users can access all databases

Action

This status message requires no action.

onspaces: unable to reset dataskip.

Cause

This error message comes from the **onspaces** utility. For some reason, the utility cannot change the specification of DATASKIP (ON or OFF) across all dbspaces in the database server instance.

Action

You are unlikely to receive this message. If the error persists after you restart the database server, Contact Technical Support.

Open transaction detected when changing log versions.

Cause

The database server detected an open transaction while it was trying to convert the data from a previous version of the database server.

Action

Conversion is not allowed unless the last record in the log is a checkpoint. You must restore the previous version of the database server, force a checkpoint, and then retry conversion.

Out of message shared memory.

Cause

The database server could not allocate more memory for the specified segment.

Action

For additional information, see the log file.

Out of resident shared memory.

Cause

The database server could not allocate more memory for the specified segment.

Action

For additional information, see the log file.

Out of virtual shared memory.

Cause

The database server could not allocate more memory for the specified segment.

Action

For additional information, see the log file.

PANIC: Attempting to bring system down.

Cause

A fatal database server error occurred.

Action

See the error that caused the panic and attempt the corrective action suggested by the error message. For additional information that might explain the failure, refer also to other messages in the message-log file.

Participant site *database_server* heuristically rolled back.

Cause

A remote site rolled back a transaction after it reached the prepared-for-commit phase.

Action

You might need to roll back the transaction on other sites and then restart it.

Physical recovery complete: *number* pages examined, *number* pages restored.

Cause

This message displays during fast recovery. The *number of pages examined* indicates the number of page images that exist in the physical log. The *number of pages restored* indicates the actual number of pages that are restored from the physical log. The number of pages restored is always less than or equal to the number examined.

The database server might physically log a page image multiple times between checkpoints. Physical recovery restores only the first logged page image.

If a page stays in the memory buffer pool, the database server physically logs it once per checkpoint, and stores one page image in the physical log. If the buffer pool is too small, a page that is being updated many times might get forced out of the buffer pool to disk and then brought back into memory for the next update. Each time the page is brought into memory, it is physically logged again, resulting in duplicate page images in the physical log.

Action

If the *number of pages examined* is much larger than the *number of pages restored,* increase the size of the buffer pool to reduce the number of duplicate before-images. For more information, see the *IBM® Informix® Performance Guide*.

Physical recovery started at page (*chunk*:*offset*).

Cause

This message displays during fast recovery. *Chunk* is the number of the chunk that contains the physical log. *Offset* is the page offset of the start of the physical log entries. Physical recovery begins restoring pages from that point.

Action

No action required. For information on fast recovery, see the *IBM® Informix® Administrator's Guide*.

Portions of partition partnum of table tablename in database dbname were not logged. This partition cannot be rolled forward.

Cause

Light appends occurred to the operational table since the last backup.

Action

If you want full access to data in this table, you need to alter the table to raw and then to the desired table type. This alter operation removes inconsistencies in the table that resulted from replaying non-logged operations such as light appends.

Possible mixed transaction result.

Cause

This message indicates that error -716 has been returned. Associated with this message is a list of the database servers where the result of a transaction is unknown.

Action

For information on determining if a transaction was implemented inconsistently, see the *IBM® Informix® Administrator's Guide*.

Prepared participant site *server_name* did not respond.

Cause

Too many attempts were made to contact remote site *server_name.* After several timeout intervals were met, the site was determined to be down.

Action

Verify that the remote site is online and that it is correctly configured for distributed transactions. Once the remote site is ready, reinitiate the transaction.

Prepared participant site *server_name* not responding.

Cause

The database server is attempting to contact remote site *server_name*. For some unknown reason, the database server cannot contact the remote site.

Action

Verify that the remote site is online and that it is correctly configured for distributed transactions.

Messages: Q-R-S

Quiescent Mode.

Cause

The database server has entered quiescent mode from some other state. On UNIX, only users logged in as **informix** or as **root** can interact with the database server. On Windows, only members of the **Informix-Admin** group can interact with the database server. No user can access a database.

Action

None required.

Read failed. Table *name*, Database *name*, iserrno = *number*

Cause

An error occurred reading the specified system table.

Action

Note the error number and contact Technical Support.

Recovery Mode.

Cause

The database server entered the recovery mode. No user can access a database until recovery is complete.

Action

None required.

Recreating index: '*dbsname*:"*owner*".*tabname-idxname*'.

Cause

After DDL statements implicitly or explicitly create one or more new indexes, but the database server terminates abnormally before the next checkpoint, re-creation of the new indexes is deferred until after logical recovery, instead of adding each index item row by row. After logical recovery ends, the server begins a parallel index build to re-create them. This message indicates when re-creation commences for each deferred index. (But if an index was dropped before the abnormal shutdown, it will not be re-created after logical recovery, and no message referencing that index will be printed.)

Action

None required.

Rollforward of log record failed, iserrno = *nn*.

Cause

The message appears if, during fast recovery or a data restore, the database server cannot roll forward a specific logical-log record. The database server might be able to change to quiescent or online mode, but some inconsistency could result. For further information, see the message that immediately precedes this one. The *iserrno* value is the error number.

Action

Contact IBM® Informix® Technical Support.

Root chunk is full and no additional pages could be allocated to chunk descriptor page.

Cause

The root chunk is full.

Action

To free space in the root chunk, take one of the following actions:

- Drop and re-create the **sysmaster** database.
- Move user tables from the root dbspace to another dbspace.
- Refragment tables.

scan_logundo: subsys *ss*, type *tt*, iserrno *ee*.

Cause

A log undo failed because log type *tt* is corrupt.

The variables in this message have the following values:

ss
: Is the subsystem name.

tt
: Is the logical-log record type.

ee
: Is the iserror number.

Action

Examine the logical log with the onlog utility to determine if any action is needed. Contact Technical Support.

Session completed abnormally. Committing *tx* id *0xm*, flags *0xn*.

Cause

Abnormal session completion occurs only when the database server is attempting to commit a transaction that has no current owner, and the transaction develops into a long transaction. The database server forked a thread to complete the commit.

Action

None required.

Session completed abnormally. Rolling back *tx* id *0xm*, flags *0xn*.

Cause

Abnormal session completion occurs only when the database server is attempting to commit a distributed transaction that has no current owner, and the transaction develops into a long transaction. The database server forked a thread that rolled back the transaction.

Action

None required.

semctl: errno = *nn*.

Cause

When the database server initialized a semaphore, an error occurred. The operating-system error is returned.

Action

See your operating-system documentation.

semget: errno = *nn*.

Cause

An allocation of a semaphore set failed. The operating-system error is returned.

Action

See your operating-system documentation.

shmat: *some_string os_errno*: *os_err_text*.

Cause

An attempt to attach to a shared-memory segment failed. The system error number and the suggested corrective action are returned.

Action

Review the corrective action (if given), and determine if it is reasonable to try. For more information, refer to your operating-system documentation.

shmctl: errno = *nn.*

Cause

An error occurred while the database server tried to remove or lock a shared-memory segment. The operating-system error number is returned.

Action

See your operating-system documentation.

shmdt: errno = *nn.*

Cause

An error occurred while the database server was trying to detach from a shared-memory segment. The operating-system error number is returned.

Action

See your operating-system documentation.

shmem sent to *filename.*

Cause

The database server wrote a copy of shared memory to the specified file as a consequence of an assertion failure.

Action

None.

shmget: *some_str os_errno*: key *shmkey*: *some_string.*

Cause

Either the creation of a shared-memory segment failed, or an attempt to get the shared-memory ID associated with a certain key failed. The system error number and the suggested corrective action are returned.

Action

Consult your operating-system documentation.

Shutdown (onmode -k) or override (onmode -O).

Cause

A dbspace has gone down during a checkpoint interval. The database server is configured to wait for an override when this situation occurs.

When the checkpoint actually happens, the following message appears: `Checkpoint blocked by down space, waiting for override or shutdown.`

Action

Either shut down the database server or issue an **onmode -O** command to override the down dbspace. For more information on the **onmode** utility, see The onmode utility.

Shutdown Mode.

Cause

The database server is in the process of moving from online mode to quiescent mode.

Action

None required.

Space *spacename* added.

Cause

The database server administrator added a new storage space *spacename* to the database server.

Action

None required.

Space *spacename* dropped.

Cause

The database server administrator dropped a storage space *spacename* from the database server.

Action

None required.

Space *spacename* -- Recovery Begins(*addr*).

Cause

This informational message indicates that the database server is attempting to recover the storage space.

The variables in this message have the following values:

spacename
: Is the name of the storage space that the database server is recovering.

addr
: Is the address of the control block.

Action

None required.

Space *spacename* -- Recovery Complete(*addr*).

Cause

This informational message indicates that the database server recovered the storage space.

The variables in this message have the following values:

spacename
: Is the name of the storage space that the database server has recovered.

addr
: Is the address of the control block.

Action

None required.

Space *spacename* -- Recovery Failed(*addr*).

Cause

This informational message indicates that the database server was unable to recover the storage space.

The variables in this message have the following values:

spacename
: Is the name of the storage space that the database server failed to recover.

addr
: Is the address of the control block.

Action

None required.

sysmaster database built successfully.

Cause

The database server successfully built the sysmaster database.

Action

None required.

Successfully extend physical log space

Cause

The physical log space was successfully extended to the file plog_extend.*servernum* under the designated path.

Action

None required.

Messages: T-U-V

This ddl operation is not allowed due to deferred constraints pending on this table and dependent tables.

Cause

This error is returned when you attempt to start a violations table and constraints are in deferred mode.

Note: No error is returned if you start a violations table and then later set the constraints to deferred. However, the violations get undone immediately rather than written into the deferred constraint buffer. For more information, see the *IBM® Informix® Guide to SQL: Syntax*.

Action

If you would like to start a violations table, you must either change the constraint mode to immediate or commit the transaction.

This type of space does not accept log files.

Cause

Adding a logical-log file to a blobspace or sbspace is not allowed.

Action

Add the logical-log file to a dbspace. For more information, see onparams -a -d dbspace: Add a logical-log file.

TIMER VP: Could not redirect I/O in initialization, errno = *nn*.

Cause

The operating system could not open the null device or duplicate the file descriptor associated with the opening of that device. The system error number is returned.

Action

See your operating-system documentation.

Too Many Active Transactions.

Cause

During a data restore, there were too many active transactions. At some point during the restore, the number of active transactions exceeded 32 kilobytes.

Action

None.

Too many violations.

Cause

The number of violations in the diagnostics table exceeds the limit that is specified in the MAX VIOLATIONS clause of the START VIOLATIONS TABLE statement. When a single statement on the target table (such as an INSERT or UPDATE statement) inserts more records into the violations table than the limit that is specified by the MAX VIOLATIONS clause, this error is returned to the user who issued the statement on the target table.

Action

To resolve this error, perform one of the following actions:

- Omit the MAX VIOLATIONS clause in the START VIOLATIONS TABLE statement when you start a violations table. Here, you are specifying no limit to the number of rows in the violations table.
- Set MAX VIOLATIONS to a high value.

Transaction Not Found.

Cause

The logical log is corrupt. This situation can occur when a new transaction is started, but the first logical-log record for the transaction is not a BEGWORK record.

Action

Contact Technical Support.

Transaction heuristically rolled back.

Cause

A heuristic decision occurred to roll back a transaction after it completed the first phase of a two-phase commit.

Action

None required.

Transaction table overflow - user id *nn*, process id *nn*.

Cause

A thread attempted to allocate an entry in the transaction table when no entries in the shared-memory table were available. The user ID and process ID of the requesting thread are displayed.

Action

Try again later.

Unable to create output file *filename* errno = *nn*.

Cause

The operating system cannot create output file *filename*. The *errno* is the number of the operating-system error returned.

Action

Verify that the directory exists and has write permissions.

Unable to extend *nn* reserved pages for *purpose* in root chunk.

Cause

The operating system cannot extend to *nn* reserved pages for *purpose* in root chunk. (The value *purpose* can be either Checkpoint/Log, DBSpace, Chunk, or Mirror Chunk.)

Action

Reduce the ONCONFIG parameter for the resource cited; bring the database server up and free some space in the primary root chunk. Then reattempt the same operation.

Unable to start SQL engine.

Cause

The database server encountered an out-of-memory condition.

Action

No action is necessary.

Unable to open tblspace *nn*, iserrno = *nn*.

Cause

The database server cannot open the specified tblspace. (The value *nn* is the hexadecimal representation of the tblspace number.)

Action

See the ISAM error message number *nn*, which should explain why the tblspace cannot be accessed. The error message appears in *IBM® Informix® Error Messages*.

The value of pagesize *pagesize* specified in the config file is not a valid pagesize. Use 2048, 4096 or 8192 as the value for PAGESIZE in the onconfig file and restart the server.

Cause

This message displays upon disk initialization. The value of PAGESIZE that was specified in the ONCONFIG file is not a valid value.

Action

Restart the database server with a valid PAGESIZE value.

Violations table is not started for the target table.

Cause

If you issue a STOP VIOLATIONS TABLE statement for which no violations table is started, you receive this message.

Action

To recover from this error, you must start a violations table for the target table.

Violations table reversion test completed successfully.

Cause

This message is recorded in the **logmessage** table in the **sysmaster** database when the **revtestviolations.sh** script has completed successfully (no open violations tables were found).

Action

No action is necessary.

Violations table reversion test failed.

Cause

When the database server finds an open violations table, it reports errors 16992 and 16993 in the **logmessage** table in the **sysmaster** database and aborts the reversion process.

Action

When this message appears, you must issue the STOP VIOLATIONS TABLE FOR *table_name* command for each open violations table. After you close all open violations tables, you can restart the reversion process.

Violations table reversion test start.

Cause

This message is recorded in the **logmessage** table in the **sysmaster** database when the **revtestviolations.sh** script is executed.

Action

No action is necessary.

Violations tables still exist.

Cause

This message is recorded in the **logmessage** table in the **sysmaster** database when an open violations table is found.

Action

When this message appears, you must issue the STOP VIOLATIONS TABLE FOR *table_name* command for each open violations table. After you close all open violations tables, you can restart the reversion process.

Virtual processor limit exceeded.

Cause

You configured the database server with more than the maximum number of virtual processors allowed (1000).

Action

Modify the value of the VPCLASS configuration parameter, the NETTYPE configuration parameter, or both.

Related reference:
NETTYPE configuration parameter
VPCLASS configuration parameter

VPCLASS *classname* name is too long. Maximum length is *maxlength*.

Cause

This message indicates an internal error.

Action

Contact Technical Support.

VPCLASS *classname* duplicate class name.

Cause

This message indicates an internal error.

Action

Contact Technical Support.

VPCLASS *classname* Not enough physical procs for affinity.

Cause

The physical processors in the affinity specification for the VP class *classname* do not exist or are offline.

Action

Make sure the named processors are online. Correct the affinity specification for the named VP class. Restart the database server.

Messages: W-X-Y-Z

WARNING: aio_wait: errno = *nn.*

Cause

While the database server was waiting for an I/O request to complete, it generated error number *nn* on an operation that it was attempting to execute.

Action

Contact Technical Support for assistance.

WARNING: Buffer pool size may cause database server to get into a locked state. Recommended minimum buffer pool size is *num* times maximum concurrent user threads.

Cause

There are not enough buffers in the buffer pool. The database server could use all available buffers and cause a deadlock to occur.

Action

Change the **buffers** field in the BUFFERPOOL parameter in the ONCONFIG file to the number that this message recommends. For more information on the BUFFERPOOL parameter, see BUFFERPOOL configuration parameter..

warning: Chunk time stamps are invalid.

Cause

A sanity check is performed on chunks when they are first opened at system initialization. The chunk specified did not pass the check and will be brought offline.

Action

Restore the chunk from a dbspace backup or its mirror.

Warning: *name_old* is a deprecated onconfig parameter. Use *name_new* instead. See the release notes and the Informix® Administrator's Reference for more information.

Cause

A deprecated ONCONFIG parameter was used. This message displays the first time that you use a deprecated parameter. The shorter form of the message displays thereafter.

Action

Use the suggested alternative ONCONFIG parameter.

Warning: *name_old* is a deprecated onconfig parameter. Use *name_new* instead.

Cause

A deprecated ONCONFIG parameter was used.

Action

Use the suggested alternative ONCONFIG parameter.

Warning: Unable to allocate requested big buffer of size *nn*.

Cause

The internal memory allocation for a big buffer failed.

Action

Increase either virtual memory size (SHMVIRTSIZE), the size of the added segments (SHMADD), or your total shared-memory size (SHMTOTAL).

You are turning off smart large object logging.

Cause

These changes will become the new sbspace default values. Changes have been made to the sbspace. The onspaces utility will read and update 100 smart large objects at a time and commit each block of 100 smart large objects as a single transaction. This utility might take a long time to complete.

Action

This informational message occurs when you issue the following command:

```
onspaces -ch sbspace -Df "LOGGING=OFF" -y
```

For more information, see onspaces -ch: Change sbspace default specifications.

Messages: Symbols

- HH:MM:SS Informix database server Version R.VV.PPPPP Software Serial Number RDS#XYYYYYY.
- argument: invalid argument.
- function_name: cannot allocate memory.

HH:MM:SS Informix® database server Version *R.VV.PPPPP* Software Serial Number RDS#*XYYYYYY*.

Cause

This message indicate the start-up of the database server, after the initialization of shared memory.

Action

No action is required.

argument: invalid argument.

Cause

This internal error indicates that an invalid argument was passed to an internal routine.

Action

Contact Technical Support.

function_name: cannot allocate memory.

Cause

The database server cannot allocate memory from internal shared-memory pool.

Action

Increase either virtual-memory size (SHMVIRTSIZE), the size of the added segments (SHMADD), or your total shared-memory size (SHMTOTAL).

Conversion and reversion error messages

If conversion or reversion is not successful, error messages are stored in the online.log file to help you identify what failed and what actions to take to fix the problem.

- Cannot revert new fragment expression for index index, tabid id.
- Cannot revert new table fragment expression for table with id id.
- The conversion of the database name has failed.
- Database name is not revertible...
- Database name: Must drop trigger (id = id_number) before attempting reversion.
- The dummy updates failed while converting database name. This may imply data corruption in the database. If so, restore the original database with the tape backup. For more information, see output_file.
- Error in slow altering a system table.
- Internal server error.
- Must drop long identifiers in table name in database name
- Must drop new database (name) before attempting reversion. Iserrno error_number
- Must drop new user defined statistics in database name, iserrno number
- The pload database contains load/unload jobs referring to long table names, column names, or database names. These jobs will not work as expected until they are redefined.
- Reversion canceled.
- There is a semi-detached index in this table, which cannot be reverted.
- WARNING: Target server version must have a certified Storage Manager installed after conversion/reversion and before bringing up server.

Cannot revert new fragment expression for index *index*, tabid *id*.

Cause

The index fragmentation was defined in a version more recent than the one to which you are reverting.

Action

Drop the problem index-fragmentation scheme and retry reversion.

Cannot revert new table fragment expression for *table* with id *id*.

Cause

The fragmentation of this table was defined in a version more recent than the one to which you are reverting.

Action

Drop the problem table fragmentation scheme and retry reversion.

The conversion of the database *name* has failed.

Cause

Indicates that the conversion of the specified database has failed.

Action

Connect to the database. This action triggers conversion of the database. If it fails, the relevant error message appears. Contact Technical Support.

Database *name* is not revertible...

Cause

The database has failed one of the reversion checks and is not revertible.

Action

Take action to correct the error displayed as a separate message.

Database *name*: Must drop trigger (id = *id_number*) before attempting reversion.

Cause

The database contains a trigger that was created in a version more recent than the one to which you are converting.

Action

Drop the trigger with the specified trigger identification number and then attempt reversion.

The dummy updates failed while converting database *name*. This may imply data corruption in the database. If so, restore the original database with the tape backup. For more information, see *output_file*.

Cause

During conversion of a database from a version earlier than version 9.2, dummy update statements are run against the system tables in the database being converted. This message indicates failure in running one of these update statements.

Action

To retry the dummy updates, run the dummy update script for your old database server version. For instructions, refer to the *IBM® Informix® Migration Guide*.

If data corruption occurred, restore the original database with the tape backup. For more information, see the *IBM Informix Backup and Restore Guide*.

Error in slow altering a system table.

Cause

An internal error occurred while performing reversion.

Action

Contact Technical Support.

Internal server error.

Cause

An unexpected error occurred during database reversion.

Action

Contact Technical Support.

Must drop long identifiers in table *name* in database *name*

Cause

Identifiers greater than 18 bytes in length are not supported in the database server version to which you are reverting.

Action

Make sure that all long identifiers in the system are either dropped or renamed before you attempt reversion.

Must drop new database (*name*) before attempting reversion. Iserrno *error_number*

Cause

The system contains a database that was created in a more recent version of the database server.

Action

Drop the new database and attempt reversion.

Must drop new user defined statistics in database *name*, iserrno *number*

Cause

Some distributions in the **sysdistrib** system table use user-defined statistics. This feature is not supported in the version to which you are reverting.

Action

Ensure that no user-defined statistics are present or used in the system and then attempt reversion.

The pload database contains load/unload jobs referring to long table names, column names, or database names. These jobs will not work as expected until they are redefined.

Cause

Printed during **onpload** reversion testing if the **onpload** database contains references to long table names, column names, or database names. But the reversion will complete.

Action

Redefine the load and unload jobs in the **onpload** database that have references to long identifiers.

Reversion canceled.

Cause

The reversion process was canceled because of errors encountered.

Action

Correct the cause of the errors, and restart reversion.

There is a semi-detached index in this table, which cannot be reverted.

Cause

A semi-detached index on this table cannot be reverted.

Action

To see the list of all semi-detached indexes, refer to the database server message log. Drop all semi-detached indexes, and retry reversion. You might need to recreate those indexes after reversion is complete.

WARNING: Target server version must have a certified Storage Manager installed after conversion/reversion and before bringing up server.

Cause

ON-Bar is being converted or reverted. The user must ensure that a storage manager, certified with the target database server version, is installed.

Action

None.

Conversion and Reversion Messages for Enterprise Replication

During conversion and reversion, specific messages are logged for Enterprise Replication by the concdr, revcdr, and revtestcdr scripts.

The scripts write the messages to standard output by default. The messages are stored in the concdr.out, revcdr.out, and revtestcdr.out files in $INFORMIXDIR/etc on UNIX or %INFORMIXDIR%\etc on Windows.

- CDR reversion test failed; for details look in $INFORMIXDIR/etc/revtestcdr.out.
- Enterprise Replication is not ready for conversion. The Control and TRG send queues should be empty for conversion/reversion to proceed.
- Enterprise Replication should be in a stopped state for conversion/reversion to proceed.
- ...'syscdr' reversion failed; for details look in $INFORMIXDIR/etc/revcdr.out.
- 'syscdr' conversion failed. For details, look in $INFORMIXDIR/etc/concdr.out.
- Syscdr should NOT contain new replicate sets for reversion to succeed.
- Syscdr should not contain replicates defined with the --floatieee option for reversion to succeed.

CDR reversion test failed; for details look in $INFORMIXDIR/etc/revtestcdr.out.

Cause

Enterprise Replication is not revertible.

Action

For more information, look at the messages in **revtestcdr.out**. Fix the reported problem before you attempt reversion.

Prints the output of the **revcdr.sh** or **revcdr.bat** script to standard output.

Enterprise Replication is not ready for conversion. The Control and TRG send queues should be empty for conversion/reversion to proceed.

Cause

There are elements in the control and Transaction Send Queue (also called TRG) send queues. The database server sends replicated data to the TRG queue before sending it to the target system.

Action

Wait for these queues to empty before you attempt either conversion or reversion. For more information, see the .

Prints this message to concdr.out during conversion or to revcdr.out during reversion.

Enterprise Replication should be in a stopped state for conversion/reversion to proceed.

Cause

Enterprise Replication should be in a stopped state for conversion or reversion to proceed.

Action

Stop Enterprise Replication. For more information, see the .

Prints this message to concdr.out during conversion or to revcdr.out during reversion.

...'syscdr' reversion failed; for details look in $INFORMIXDIR/etc/revcdr.out.

Cause

The reversion of the syscdr database failed.

Action

Find the cause of failure in the **revcdr.out** file, then fix the problem before you attempt reversion.

Prints the output of the **revcdr.sh** or **revcdr.bat** script to standard output.

'syscdr' conversion failed. For details, look in $INFORMIXDIR/etc/concdr.out.

Cause

Conversion of the **syscdr** database failed.

Action

If conversion fails, resolve the problem reported in **concdr.out**. Restore the **syscdr** database from backup and reattempt conversion.

Prints the output of the **concdr.sh** or **concdr.bat** script to standard output.

Syscdr should NOT contain new replicate sets for reversion to succeed.

Cause

The new replicate sets in the **syscdr** database are not compatible with older versions.

Action

Use the **cdr delete replicateset** command to delete the replicate sets. Then rerun the **revcdr.sh** or **revcdr.bat** script to reattempt reversion.

Prints this message to **revtestcdr.out**.

Syscdr should not contain replicates defined with the --floatieee option for reversion to succeed.

Cause

Replicates have been defined with the **--floatieee** option. You cannot revert these replicates to the older version.

Action

Use the **cdr delete replicateset** command to delete replicates defined with the **--floatieee** option, then reattempt reversion.

Prints this message to **revtestcdr.out**.

Dynamic Log Messages

Dynamically added log file *logid* to DBspace *dbspace_number*.

Cause

The next active log file contains records of an open transaction. Whenever the database server adds a log dynamically, it logs this message. Example: `Dynamically added log file 38 to DBspace 5`.

Action

Complete the transaction as soon as possible.

Log file *logid* added to DBspace *dbspace_number*.

Cause

Whenever the administrator adds a log file manually, the database server logs this message. Example: `Log file 97 added to Dbspace 2`.

Action

None required.

Log file number *logid* has been dropped from DBspace *dbspace_number*.

Cause

When you drop a newly-added log file, the database server logs this message. Example: `Log file number 204 has been dropped from DBspace 17`.

Action

None required.

Log file *logid* has been pre-dropped.

Cause

When you drop a used log file, it is marked as deleted (status **D**) and cannot be used again. After you perform a level-0 backup, the database server drops this log file and can reuse the space. Example: `Log file 12 has been pre-dropped.`

Action

To delete the log file, perform a level-0 backup of all storage spaces.

Pre-dropped log file number *logid* has been deleted from DBspace *dbspace_number*.

Cause

After a backup, the database server deletes a pre-dropped log file and logs this message. Example: `Pre-dropped log file number 12 has been deleted from DBspace 3.`

Action

None required.

ALERT: Because the oldest logical log (*logid*) contains records from an open transaction (*transaction_address*), the server is attempting to dynamically add a log file. But there is no space available. Please add a DBspace or chunk. Then complete the transaction as soon as possible.

Cause

If the database server is unable to dynamically add a log file because the instance is out of space, it logs this message.

Action

Add a dbspace or chunk to an existing dbspace. Then complete the transaction as soon as possible.

ALERT: The oldest logical log (*logid*) contains records from an open transaction (*transaction_address*). Logical logging will remain blocked until a log file is added. Add the log file with the onparams -a command, using the -i (insert) option, as in: onparams -a -d *dbspace* -s *size* -i. Then complete the transaction as soon as possible.

Cause

If the DYNAMIC_LOGS parameter is set to `1`, the database server prompts the administrator to add log files manually when they are needed.

Action

Use the **onparams -a** command with the **-i** option to add the log file after the current log file. Then complete the transaction as soon as possible.

Log file *logid* has been pre-dropped. It will be deleted from the log list and its space can be reused once you take level-0 archives of all BLOBspaces, Smart BLOBspaces and non-temporary DBspaces.

Cause

When you drop a used log file, it is marked as deleted (status **D**) and cannot be used again, and **onparams** prints this message.

Action

To delete the log file, perform a level-0 backup of all storage spaces.

Sbspace Metadata Messages

Allocated *number* pages to Metadata from chunk *number*.

Cause

The database server freed the specified number of pages from the reserved area and moved them to the metadata area of chunk *number*.

Action

None required.

Allocated *number* pages to Userdata from chunk *number*.

Cause

The database server freed the specified number of pages from the reserved area and moved them to the user-data area of chunk *number*.

Action

None required.

Freeing reserved space from chunk *number* to Metadata.

Cause

The metadata area in chunk *number* is full. The database server is trying to free space from the reserved area to the metadata area.

Action

None required.

Freeing reserved space from chunk *number* to Userdata.

Cause

The user-data area in chunk *number* is full. The database server is trying to free space from the reserved area to the user-data area.

Action

None required.

Truncate Table Messages

- The table cannot be truncated if it has an open cursor or dirty readers.
- The table cannot be truncated. It has at least one non-empty child table with referential constraints.

The table cannot be truncated if it has an open cursor or dirty readers.

Cause

You must have exclusive access to the table.

Action

Wait for dirty readers to complete or close all the open cursors and reissue the TRUNCATE TABLE command.

The table cannot be truncated. It has at least one non-empty child table with referential constraints.

Cause

You cannot truncate a table if it has child tables with referential constraints and at least one row.

Action

Empty the child tables before you truncate this table.

Limits in Informix

This topic lists the system-level and table-level parameter limits, the system defaults, and the access capabilities of Informix®.

- System-Level Parameter Limits
- Table-level parameter limits
- Informix System Defaults
- Access capabilities

System-Level Parameter Limits

Table 1. System-level parameter limits

System-Level Parameters	Maximum Capacity per Computer System
IBM® Informix systems per computer (Dependent on available system resources)	255
Maximum number of accessible remote sites	Machine specific
Maximum virtual shared memory segment (SHMVIRTSIZE)	2GB (32-bit platforms) or 4TB (64-bit platforms)
Maximum number of Informix shared memory segments	1024

System-Level Parameters	Maximum Capacity per Computer System
Maximum address space	UNIX: Machine specific Windows: 2.7 GB if 4-gigabyte tuning is enabled: • All Windows versions later than Windows 2003 • Windows 2003 and earlier versions if the boot.ini file contains the /3GB switch 1.7 GB for Windows 2003 and earlier versions if the boot.ini file does not contain the /3GB switch

Table-level parameter limits

Table 2. Table-level parameter limits

Table-level parameters (2K page size unless otherwise stated)	Maximum capacity per table
Data rows per page	255
Data rows per fragment	4,277,659,295
Data pages per fragment	16,775,134
Data bytes per fragment (excludes smart large objects (BLOB, CLOB) and simple large objects (BYTE, TEXT) created in blobspaces	2K page size = 33,818,670,144 4K page size = 68,174,144,576 8K page size = 136,885,093,440 12K page size = 205,596,042,304 16K page size = 274,306,991,168
Binary large object BLOB/CLOB pages	4 TB
Binary large objects TEXT/BYTE bytes	4 TB
Row length	32,767
Number of columns	32K
Maximum number of pages per index fragment	2,147,483,647
Key parts per index	16
Columns per functional index	102 (for C UDRs) 341 (for SPL or Java™ UDRs)
Maximum bytes per index key:	2K page size = 387 4K page size = 796 8K page size = 1615 12K page size = 2435 16K page size = 3254
Maximum size of an SQL statement	Limited only by available memory

Informix System Defaults

Table 3. System defaults

Database characteristic	Informix system default
Table lock mode	Page
Initial extent size	8 pages
Next extent size	8 pages
Read-only isolation level (with database transactions)	Committed Read
Read-only isolation level (ANSI-compliant database)	Repeatable Read

Access capabilities

Table 4. Access capabilities

Access Capabilities	Maximum Capacity per System
Maximum databases per Informix system	21 million
Maximum tables per Informix system	477 102 080
Maximum active users per Informix (minus the minimum number of system threads)	32K user threads
Maximum active users per database and table (also limited by the number of available locks, a tunable parameter)	32K user threads
Maximum number of open databases in a session	UNIX: 32 databases Windows: 8 databases
Maximum number of open tables per Informix system	Dynamic allocation
Maximum number of open tables per user and join	Dynamic allocation

Access Capabilities	Maximum Capacity per System
Maximum number of open transactions per instance	32 767
Maximum locks per Informix system and database	Dynamic allocation
Maximum number of page cleaners	128
Maximum number of partitions per dbspace	4K page size: 1048445, 2K page size: 1048314 (based on 4-bit bitmaps)
Maximum number of recursive synonym mappings	16
Maximum number of tables locked with LOCK TABLE per user	32
Maximum number of cursors per user	Machine specific
Maximum Enterprise Replication transaction size	4 TB
Maximum dbspace size	131 PB
Maximum sbspace size	131 PB
Maximum chunk size	4 TB
Maximum number of chunks	32 766
Maximum number of 2K pages per chunk	2 billion
Maximum number of open Simple Large Objects (applies only to TEXT and BYTE data types)	20
Maximum number of B-tree levels	20
Maximum amount of decision support memory	Machine specific
Utility support for large files	17 billion GB
Maximum number of storage spaces (dbspaces, blobspaces, sbspaces, or extspaces)	2047

DB-Access User's Guide

This publication describes how to use the DB-Access utility to access, modify, and retrieve information from IBM® Informix® database servers.

Important: Use DB-Access with the current version of the database server. If you use DB-Access with a database server from a different version, you might obtain inconsistent results, such as when you use a version that does not support long identifiers with a version that does.
This publication is written for the following users:

- Database users
- Database administrators
- Database-application programmers

This publication assumes that you have the following background:

- A working knowledge of your computer, your operating system, and the utilities that your operating system provides
- Some experience working with relational databases or exposure to database concepts
- Some experience with computer programming

These topics are taken from *IBM Informix DB-Access User's Guide*.

- Getting started with DB-Access
  DB-Access provides a menu-driven interface for entering, running, and debugging Structured Query Language (SQL) statements and Stored Procedure Language (SPL) routines. You can also run DB-Access interactively from the command line.
- The full-screen menu interface
  The DB-Access full-screen menu interface guides you through running SQL statements.
- Appendixes

Getting started with DB-Access

DB-Access provides a menu-driven interface for entering, running, and debugging Structured Query Language (SQL) statements and Stored Procedure Language (SPL) routines. You can also run DB-Access interactively from the command line.

You use SQL and SPL commands to perform data-definition tasks, such as specifying the number and type of data columns in a table, and data-management tasks, such as storing, viewing, and changing table data.

You can use DB-Access for the following aspects of database processing:

- Running ad hoc queries that you run infrequently
- Connecting to one or more databases, transferring data between the database and external text files, and displaying information about a database
- Displaying system catalog tables and the Information Schema of databases
- Practicing the SQL and SPL statements and examples that are provided in the *IBM Informix Guide to SQL: Tutorial* or the *IBM Informix Database Design and Implementation Guide*
- Testing applications that you intend to store for use in a production environment
- Creating demonstration databases

Important: DB-Access is not intended as an application-development environment. You cannot branch conditionally or loop through SQL statements when you run them within DB-Access.
The DB-Access utility is included with the Informix® server and with the Informix Client Software Development Kit.

- Requirements for the Informix server DB-Access utility
  Before you start DB-Access, prepare the Informix server environment.
- Requirements for the Informix Client Software Development Kit DB-Access utility
  Before you start DB-Access on a client, set up the client environment.
- Demonstration databases
  You can practice using DB-Access with a demonstration database.
- Start DB-Access
  You start DB-Access by running the **dbaccess** command from the command line. You can choose whether to use the DB-Access menu interface or the command-line interface.

Requirements for the Informix server DB-Access utility

Before you start DB-Access, prepare the Informix® server environment.

Do the following tasks before you start the DB-Access utility that is included with the Informix server:

- Set environment variables
- If you require globalization, set up the Global Language Support (GLS) locale
- Start the database server

To secure DB-Access connections with IBM® Informix, you can use the Secure Sockets Layer (SSL) protocol.

- Environment variables for DB-Access
  As part of the installation and setup process, the system or database administrator sets certain environment variables that enable IBM Informix products to work within a particular operating-system environment.

Related information:
Secure sockets layer protocol

Environment variables for DB-Access

As part of the installation and setup process, the system or database administrator sets certain environment variables that enable IBM® Informix® products to work within a particular operating-system environment.

You must have $INFORMIXDIR/bin in your path if you use DB-Access on a UNIX operating system or %INFORMIXDIR%\bin in your path if you use DB-Access on a Windows operating system. Your operating system uses the path to locate the initialization script and the **dbaccess** executable file.

In a UNIX environment, the database server must have the appropriate terminal that is set up from among the terminals that are listed by the INFORMIXTERM environment variable.

DB-Access uses the terminal definitions in the terminfo directory unless the INFORMIXTERM environment variable is set to the termcap file. If DB-Access fails to initialize the menus that are based on the INFORMIXTERM setting, DB-Access tries to use the other setting. For example, if DB-Access fails to initialize the menus using the terminfo directory, DB-Access starts the menus using the termcap file.

You can set the following optional environment variables:

DBACCNOIGN
: Rolls back an incomplete transaction if you run the LOAD command in menu mode.

DBCENTURY
: Sets the appropriate expansion for DATE and DATETIME values that have only a two-digit year, such as 04/15/12.

DBDATE
: Specifies the user formats of DATE values.

DBEDIT
: Sets the default DB-Access text editor without changing the default text editor that is associated with the operating-system shell.
For more information about how DB-Access uses the text editor that you specify as default, see A system editor.

DBFLTMASK
: Sets the default floating-point values of data types FLOAT, SMALLFLOAT, and DECIMAL within a 14-character buffer.
The effect of this variable is limited to the DB-Access display size for numbers.

DELIMIDENT
: Causes the database server to interpret double quoted (“) text as identifiers rather than strings.

IFX_LONGID
: Determines whether a client application can handle long identifiers.
If you use the IFX_LONGID environment variable to support SQL identifiers with up to 128 bytes, some error, warning, or other messages of DB-Access might truncate database object names that include more than 18 bytes in their identifiers. You can avoid this truncation by not declaring names that have more than 18 bytes.

GL_DATETIME
: Defines the end-user formats for data values in DATETIME columns. In databases where GL_DATETIME has a nondefault setting, you must also set the USE_DTENV environment variable to `1` for user formats to be applied correctly in some load and unload operations.
Important:
The `%F` directive implies no default separator between the SECOND and FRACTION fields of DATETIME values. Defining no separator before the `%F` directive concatenates SECOND and FRACTION values, as in the following example, where GL_DATETIME has this setting:

```
%Y-%m-%d %H:%M:%S%F
```

Below is the end-user display for a DATETIME YEAR TO FRACTION(2) value on August 23, 2013, at exactly 53 seconds after 1:15 PM:

```
2013-08-23 13:15:5300
```

Here `5300` represents 53 seconds, concatenated with the FRACTION precision of 2. To display a separator between the integer and fractional parts of the seconds value, your GL_DATETIME setting must include a literal separator character immediately before the `%F` formatting directive.

Environment variables

Requirements for the Informix Client Software Development Kit DB-Access utility

Before you start DB-Access on a client, set up the client environment.

The DB-Access utility on a client can directly access Informix® databases with which Client SDK has a client/server connection.

Do the following tasks before you start DB-Access utility that is included with Client SDK:

- Set the client/server connectivity information in the sqlhosts file.
  - If you renamed the file or moved it from the default location, set the INFORMIXSQLHOSTS environment variable to the full path name and file name of the file that contains the connectivity information.
  - You can use the **syncsqlhosts** utility to convert connection information from the Windows registry format to the sqlhosts file format.
- Set the INFORMIXDIR environment variable to the Client SDK installation directory.
- Set the INFORMIXSERVER environment variable for a default server name.

The syncsqlhosts utility

Demonstration databases

You can practice using DB-Access with a demonstration database.

If you use IBM® Informix® demonstration databases, you can add, delete, or change the provided data and scripts. You can restore the database to its original condition.

You can configure the following demonstration databases:

- The **stores_demo** database illustrates a relational schema with tables about a fictitious wholesale sporting-goods distributor, as well as other tables that are used in examples. Tables containing electricity usage and geographical location data illustrate time series and spatial information. Many examples in IBM Informix manuals are based on the **stores_demo** database.
- The **superstores_demo** database illustrates an object-relational schema. The **superstores_demo** database contains examples of extended data types, type and table inheritance, and user-defined routines.

The scripts that you use to install the demonstration databases are in the $INFORMIXDIR/bin directory on UNIX and in the %INFORMIXDIR%\bin directory on Windows.

Some operating systems require that you have execute permissions to run SQL command files, read permissions to open these files or their contents in DB-Access, or write permissions to save modified or new files. Use the UNIX **chmod** command to enable execution of the SQL files that the initialization script installed.

The demonstration scripts are designed for the default locale. If you use a non-default locale, such as **en_us.utf8**, some features, such as the SET COLLATION statement, might not function correctly.

- Creating a demonstration database
  You create demonstration databases by running the **dbaccessdemo** command.
- dbaccessdemo command: Create demonstration databases
  Use the **dbaccessdemo** or **dbaccessdemo_ud** command to create the demonstration databases.

Related information:
The stores_demo Database
The superstores_demo database

Creating a demonstration database

You create demonstration databases by running the **dbaccessdemo** command.

When you create a demonstration database, the script confirms that you want to copy sample SQL command files. Command files that the demonstration database includes have a .sql extension and contain sample SQL statements that you can use.

To create a demonstration database:

1. Create a directory.

You must have UNIX read and execute permissions for each directory in the path name that you create.

2. Change directories to the new directory and run the **dbaccessdemo** or **dbaccessdemo_ud** command.
3. The initialization script displays a series of messages on the screen as the database is created. Press Y to copy the command files into the directory that you created. The demonstration database is created. You are the owner and database administrator (DBA) of that database.

If you want to discard changes that you made to your database or to the command files, rerun the **dbaccessdemo** or **dbaccessdemo_ud** command and press Y to replace the existing command files with the original versions.

dbaccessdemo command: Create demonstration databases

Use the **dbaccessdemo** or **dbaccessdemo_ud** command to create the demonstration databases.

Syntax for stores_demo

```
>>-dbaccessdemo--+-------+--+---------+-------------------------->
                 '- -log-'  '-dbname-'

>--+-------------------------+--+---------+--------------------><
   '- -dbspace--dbspace_name-'  '- -nots-'
```

Syntax for superstores_demo

```
>>-dbaccessdemo_ud--+-------+--+---------+----------------------->
                    '- -log-'  '-dbname-'

>--+-------------------------+---------------------------------><
   '- -dbspace--dbspace_name-'
```

-log
: Requests transaction logging for the demonstration database.

dbname
: Substitutes for the default database name. Must follow Identifier naming guidelines.

-dbspace
: Requests a particular dbspace location for the demonstration database.

dbspace_name
: Houses the demonstration database. If you do not specify a dbspace name, by default, the data for the database is put in the root dbspace. To create a dbspace, use the **onspaces** utility.

-nots
: Prevents the creation of the time series tables in the **stores_demo** database.

Examples

The following command creates a database that is named **stores_demo**:

```
dbaccessdemo
```

The following example creates an instance of the **stores_demo** database named **demo_db**:

```
dbaccessdemo demo_db
```

The following command initializes the **stores_demo** database and also initiates log transactions:

```
dbaccessdemo -log
```

The following command creates an instance of the **stores_demo** database named **demo_db** in **dbspace_2**:

```
dbaccessdemo demo_db -dbspace dbspace_2
```

The following command creates a database that is named **superstores_demo**:

```
dbaccessdemo_ud
```

Related information:
The stores_demo Database
The superstores_demo database
Identifier

Start DB-Access

You start DB-Access by running the **dbaccess** command from the command line. You can choose whether to use the DB-Access menu interface or the command-line interface.

You can start and use DB-Access in the following ways:

- Start DB-Access at the main menu.
- Start DB-Access from a specific menu or screen.
- Run a file that contains SQL statements without showing the DB-Access menus.
- Start and run DB-Access interactively at the command line, without the menu interface.

On Windows, you can set up the DB-Access program icon to run any of the **dbaccess** commands.

If the TERM, TERMCAP, or TERMINFO environment variables on UNIX do not enable DB-Access to recognize the type of terminal you use, the main menu does not show. Instead, a message similar to the following text is displayed:

```
Unknown terminal type.
```

If you use a window interface on a UNIX terminal, issue the **dbaccess** command from a nonscrolling console window.

If you use a Windows terminal to run DB-Access on a UNIX database server, the terminal-emulation window must emulate a terminal type that DB-Access can recognize, or the database server shows an unknown terminal-type message in the terminal-emulation window.

Tip: If your operating system cannot find **dbaccess**, include the full path before the program name, as follows:

```
$INFORMIXDIR/bin/dbaccess
```

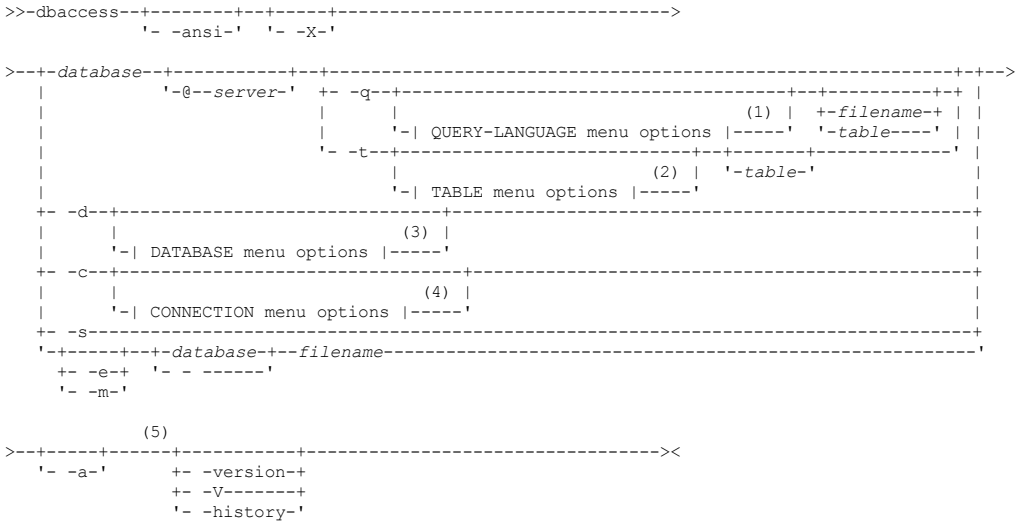
- dbaccess command: Start DB-Access
  Use the **dbaccess** command to start DB-Access. Include options to specify the database, command files, or to go to a specific menu screen.
- Run DB-Access in interactive mode without menus
  If you do not want to use the menus and do not have a prepared SQL file, use your keyboard or standard input device to enter SQL statements from the command line.

Related concepts:
Requirements for the Informix Client Software Development Kit DB-Access utility
Related information:
Environment variables

dbaccess command: Start DB-Access

Use the **dbaccess** command to start DB-Access. Include options to specify the database, command files, or to go to a specific menu screen.

Syntax



Notes:

1. See QUERY-LANGUAGE menu options.
2. See TABLE menu options.
3. See DATABASE menu options.
4. See CONNECTION menu options.
5. Cannot be combined with any other option.

The **dbaccess** command without options starts the main menu with no database selected and no options activated. You select submenus from the main menu.

-ansi
: Causes DB-Access to generate a warning whenever it encounters IBM® Informix® extension to ANSI-compliant syntax. For more information, see Example: Check for ANSI compliance.

-a
: Stops a process directly after the first error is encountered. Stopping a process from continuing after the first error can ensure greater database consistency.

-c
: Starts with the CONNECTION menu as the top-level menu.

-d

Starts with the DATABASE menu as the top-level menu.

-e
Echoes each line from a command file designated by *filename*.

-history
Can be abbreviated to **-his**. Displays the previous commands that you ran from the **dbaccess** command line during the current session. Commands that you ran from the menu interfaces are not shown. Each command is numbered. In the interactive mode without menus, you can rerun previous commands with the following command:

```
run number
```

The *number* is the number of the command to run. For an example, see Run DB-Access in interactive mode without menus.

-m
Displays all error messages generated by multiple levels of the server that pertain to an SQL statement in command files.

-q
Starts at the query-language menu (SQL-menu) as the top-level menu.

-s
Connects you to the main DB-Access menu and displays information about the current session.
This information includes database server name, database server type, the host computer, server capabilities, and other settings.

-t
Starts at the TABLE menu as the top-level menu.

-V
Displays the version number and serial number for DB-Access without launching the application. You cannot use any other options with **-V**.

-version
Displays the version number and build information for DB-Access, including the GLS library version, without launching the application. You cannot use any other options with **-version**.

-X
Activates the hexadecimal format for LOAD and UNLOAD statements.

database
Name of the database that you want DB-Access to connect to at the startup of your current session. A hyphen (-) indicates that the database is specified in a DATABASE statement in a command file.

filename
Names a command file to load with the SQL menu.

server
Name of the database server.

table
Specifies a table in the database.

If you exit from a submenu or option that you specified from the command line, you will exit directly to the operating-system command line.

- CONNECTION menu options
  The CONNECTION menu options for the **dbaccess** command represent short cut keys for the CONNECTION menu.
- DATABASE menu options
  The DATABASE menu options for the **dbaccess** command represent short cut keys for the DATABASE menu.
- QUERY-LANGUAGE menu options
  The QUERY-LANGUAGE menu options for the **dbaccess** command represent short cut keys for the QUERY-LANGUAGE menu.
- TABLE menu options
  The TABLE menu options for the **dbaccess** command represent short cut keys for the TABLE menu.
- Example: Start DB-Access for a database
  This example shows how to start DB-Access and specify a database to which to connect.
- Example: Run a command file
  This example shows how to start DB-Access and run a command file that contains SQL statements.
- Example: View the Information Schema
  This example shows how to start DB-Access and view the Information Schema for the specified database.
- Example: Check for ANSI compliance
  This example shows how to start DB-Access and check whether a database is ANSI-compliant.
- Example: Show nonprintable characters in hexadecimal
  This example starts DB-Access and activates the hexadecimal load and unload format (XLUF) so that the LOAD and UNLOAD SQL statements can format nonprintable ASCII signs in hexadecimal format.

CONNECTION menu options

The CONNECTION menu options for the **dbaccess** command represent short cut keys for the CONNECTION menu.

-cc
Chooses the Connect option on the CONNECTION menu.

-cd
Chooses the Disconnect option on the CONNECTION menu.

DATABASE menu options

The DATABASE menu options for the **dbaccess** command represent short cut keys for the DATABASE menu.

-dc
Chooses the Create option on the DATABASE menu.

-dcl
Takes you to the LOG option on the CREATE DATABASE menu

-dd
Chooses the Drop option on the DATABASE menu.

-di
Chooses the Info option on the DATABASE menu. With this option, you can add another letter as follows to go to the next menu level and view:

-dib
The dbspaces information for the current database

-din
The NLS information for the current database

-dip
Stored procedures in the current database

If you do not include a database name before any **-di** option, you must choose a current database from the SELECT DATABASE screen.

-dl
Chooses the CLose option on the DATABASE menu.

-ds
Chooses the Select option on the DATABASE menu.

QUERY-LANGUAGE menu options

The QUERY-LANGUAGE menu options for the **dbaccess** command represent short cut keys for the QUERY-LANGUAGE menu.

-qc
Chooses the Choose option on the SQL menu.

-qd
Chooses the Drop option on the SQL menu.

-qi
Chooses the Info option on the SQL menu. With this option, you can add another letter as shown in the following list (and specify a table) to go to the next menu level and view:

-qic
Columns in the table

-qif
Information about fragmentation strategy for the table

-qig
Information about triggers in the table

-qii
Indexes on the table

-qio
Table constraints

-qip
Access privileges on the table

-qir
Table-level references privilege on the table

-qis
Table status information

If you do not include a table name with the **-qi** option, you must choose one from the INFO FOR TABLE screen.

-qm
Chooses the Modify option on the SQL menu.

-qn
Chooses the New option on the SQL menu.

-qs
Chooses the Save option on the SQL menu.

-qu
Chooses the Use-editor option on the SQL menu.
If you do not include a database name before a **-q** option, you must choose a current database from the SELECT DATABASE screen.

When you select the Modify option on the QUERY-LANGUAGE menu, you must first select a command file to modify from the CHOOSE menu. The MODIFY screen is then displayed and shows the text.
Restriction: You cannot go directly to the Run or Output option on the SQL menu. Trying to do so results in an error message.

TABLE menu options

The TABLE menu options for the **dbaccess** command represent short cut keys for the TABLE menu.

-ta
Chooses the Alter option on the TABLE menu.

-tc
Chooses the Create option on the TABLE menu.

-td
Chooses the Drop option on the TABLE menu.

-ti
: Chooses the Info option on the TABLE menu. With this option, you can add another letter as shown in the following list (and specify a table) to go to the next menu level and view:

  -tic
  : Columns in the table
  -tif
  : Information about fragmentation strategy for the table
  -tig
  : Information about triggers in the table
  -tii
  : Indexes on the table
  -tio
  : Table constraints
  -tip
  : Access privileges on the table
  -tir
  : Table-level references privilege on the table
  -tis
  : Table status information

  If you do not include a table name with the **-ti** option, you must choose one from the INFO FOR TABLE screen.

  If you do not include a database name before a **-t** option, you must choose a current database from the SELECT DATABASE screen.

Example: Start DB-Access for a database

This example shows how to start DB-Access and specify a database to which to connect.

Assume that the database server that you have online contains a database named **mystores**. To make the **mystores** database the current database, start DB-Access with the following command:

```
dbaccess mystores
```

You can specify a database on a database server that is not online. For example, either of the following commands selects the **newstores** database on the **xyz** database server:

```
dbaccess newstores@xyz
dbaccess //xyz/newstores
```

When DB-Access starts, the database and database server name that you specify are displayed on the dashed line, as the following figure shows.
Figure 1. The DB-Access main menu with database and database server name

```
DB-Access:   Query-language  Connection  Database  Table  Session  Exit

---------------- newstores@xyz ---------------------Press CTRL-W for Help ---
```

Example: Run a command file

This example shows how to start DB-Access and run a command file that contains SQL statements.

The following sample command runs the SQL statements in a file named sel_stock.sql on the **mystores** database:

```
dbaccess mystores sel_stock
```

The following sample command runs the SQL statements in the sel_all.sql file on the database that file specifies:

```
dbaccess - sel_all.sql
```

Some operating systems require that you have execute permissions to run SQL command files, read permissions to open these files or their contents in DB-Access, or write permissions to save modified or new files.

Use the UNIX **chmod** command to enable execution of the SQL files that the initialization script installed.

Example: View the Information Schema

This example shows how to start DB-Access and view the Information Schema for the specified database.

The xpg4_is.sql file in the $INFORMIXDIR/etc directory creates the Information Schema and installs the views for a specified database. The following command creates the Information Schema for database **mystores**:

```
dbaccess mystores $INFORMIXDIR/etc/xpg4_is.sql
```

The Information Schema adds to the database four information-only views that conform to X/Open XPG4 with IBM® Informix® extensions. After you run xpg4_is.sql, use DB-Access to retrieve information about the tables and columns that you have access to in the specified database.
Tip: Do not install XPG4-compliant views on an ANSI database, because the format of XPG4-compliant views differs considerably from the format of the ANSI-compliant Information Schema views that are defined by the SQL standards committee.

Related information:
Information Schema

Example: Check for ANSI compliance

This example shows how to start DB-Access and check whether a database is ANSI-compliant.

To check your SQL statements for compliance with ANSI standards, include the **-ansi** option or set the DBANSIWARN environment variable. Use the **-ansi** option with other **dbaccess** options such as **-dc** (to create a database), **-tc** or **-ta** (to create or alter a table), or **-qc *filename*** (to choose a command file). The following command checks for ANSI compliance while DB-Access creates the database **research**:

```
dbaccess -ansi -dc research
```

You do not need to specify the **-ansi** option on the command line if the DBANSIWARN environment variable is set.

DB-Access displays the SQLSTATE value with the warning under the following circumstances:

- You include the **-ansi** option or set the DBANSIWARN environment variable.
- You access or create an ANSI database.
- You run DB-Access in command-line mode or specify a .sql input file.
- Running an SQL statement generates a warning rather than an error.

Related information:
DECIMAL(p) Floating Point
GET DIAGNOSTICS statement
DBANSIWARN environment variable
ANSI-Compliant Databases

Example: Show nonprintable characters in hexadecimal

This example starts DB-Access and activates the hexadecimal load and unload format (XLUF) so that the LOAD and UNLOAD SQL statements can format nonprintable ASCII signs in hexadecimal format.

The following command activates the XLUF format for the **mystores** database:

```
dbaccess -X mystores
```

A .unl file that the UNLOAD statement produces contains the hexadecimal format changes.

Related information:
The LOAD and UNLOAD statements

Run DB-Access in interactive mode without menus

If you do not want to use the menus and do not have a prepared SQL file, use your keyboard or standard input device to enter SQL statements from the command line.

When you start DB-Access without a menu argument and with a hyphen as the final argument, DB-Access processes commands from the standard input device (on UNIX) or the keyboard (on Windows). DB-Access reads what you type until you indicate that the input is completed. Then DB-Access processes your input and writes the results to the standard output device (on UNIX), or the command window (on Windows).

DB-Access reads and runs SQL statements from the terminal keyboard interactively. While DB-Access runs interactively, the greater than (>) prompt marks the line where you type your next SQL statement.

When you type a semicolon (;) to end a single SQL statement, DB-Access processes that statement. When you press CTRL-D to end the interactive session, DB-Access stops running. The following example shows user input and results in an interactive session:

```
dbaccess - -
>database stores_demo;

Database selected.

>select count(*) from systables;

(count(*))

     21

1 row(s) retrieved.

>^D

dbaccess - -
>database stores_demo;

Database selected.

>select count(*) from systables;

(count(*))
```

```
     21

1 row(s) retrieved.

>^D
```

Batch command input (UNIX)

You can use an inline shell script to supply one or more SQL statements. For example, you can use the UNIX C, Bourne, or Korn shell with inline standard input files:

```
dbaccess mystores- <<EOT!
select avg(customer_num) from customer
where fname matches '[A-G]*';
EOT!
```

You can use a pipe to supply SQL statements, as in this UNIX example:

```
echo 'select count(*) from systables' | dbaccess mystores
```

DB-Access interprets any line that begins with an exclamation mark (!) as a shell command. You can mix shell escape lines with SQL statements and put them in SQL statements, as follows:

```
dbaccess mystores -
>select
!echo hello
>hello
count(*) from systables;
>
(count(*))

     21

1 row(s) retrieved.
>
```

View and rerun DB-Access commands

You can view and rerun DB-Access commands that you ran from the command line during the current session.

To view the previous commands, run the **dbaccess -history** command. In the following example, the command history shows three previous commands:

```
dbaccess -history - -
1> create database sales_demo;

Database created.

2> create table customer (
2>         customer_code integer,
2>         customer_name char(31),
2>         company_name char(20));

Table created.

3> insert into customer values (102, "Carole Sadler", "Sports Spot");

1 row(s) inserted.

4> history;

1   create database sales_demo
2   create table customer (
           customer_code integer,
           customer_name char(31),
           company_name char(20))
3   insert into customer values (102, "Carole Sadler", "Sports Spot")
```

You can rerun the third command by running the **run 3** command:

```
4> run 3;

1 row(s) inserted.
```

- Connect to a database environment in interactive mode
  You can use the CONNECT . . . USER syntax in SQL statements that you issue in interactive mode. However, DB-Access does not support the USER clause of the CONNECT statement when you connect to a default database server.

Connect to a database environment in interactive mode

You can use the CONNECT . . . USER syntax in SQL statements that you issue in interactive mode. However, DB-Access does not support the USER clause of the CONNECT statement when you connect to a default database server.

When you include the USER '*user identifier*' clause in a CONNECT statement in interactive mode, DB-Access prompts you to enter a password.

The following two command examples show how to connect to a database server in interactive mode. The first example uses the CONNECT statement without specifying a user identifier.

```
dbaccess -nohistory- -

> connect to '@starfish';

Connected.
```

If you include the USER clause in a CONNECT statement, as the second example shows, DB-Access uses echo suppression to prompt you for a password:

```
> connect to '@starfish' user 'marae';

ENTER PASSWORD:

Connected.
```

Restriction: For security reasons, do not enter the password on the screen where it can be seen. Also, do not include the USING *password* clause in a CONNECT statement when you use DB-Access interactively. If you are in interactive mode and attempt to enter a password before the prompt, an error message is displayed.
You can run the USER clause of a CONNECT statement in a DB-Access file that includes the USER clause. The following example uses a command file that contains a CONNECT statement with a USING clause to connect to a database server:

```
dbaccess - connfile.sql
```

Important: An SQL command file that contains the following statement is protected from access by anyone other than the **user_id** that the USER clause identifies:

```
CONNECT TO '@dbserver' USER 'user_id' USING password
```

For UNIX, the following example uses a shell file to connect to a database server. DB-Access prompts you for a password.

```
dbaccess - - <<\!
connect to '@starfish' user 'marae';
!

ENTER PASSWORD:
```

Here the delimiting quotation marks preserve letter case in the database server name and in the authorization identifier of the user.

The full-screen menu interface

The DB-Access full-screen menu interface guides you through running SQL statements.

The DB-Access user interface combines the following features:

- A hierarchy of menus
- Screens that prompt you for brief responses and choices from selection lists
- Contextual HELP screens
- The interactive Schema Editor that helps you structure tables
- An SQL programmer environment, which includes the following features:
  - The built-in SQL editor where you enter and modify SQL and SPL statements
  - An option to use another editor of your choice
  - The database server syntax checker and runtime debugger
  - Storage, retrieval, and execution of SQL and SPL routines
- A choice of output for database queries and reports

- The Query-language option
  Use the Query-language option to enter, modify, save, retrieve, and run SQL statements. DB-Access retains the statements, if any, in the editor. These statements are called the *current* statements.
- The Database option
  Use the Database option to work with databases and transactions.
- The Table option
  Use the Table option to work with tables.
- The Connection and Session options
  Use the Connection option if you want to connect to a specific database server and database or explicitly disconnect from the current database environment. Use the Session option to display information about the current DB-Access session.

The Query-language option

Use the Query-language option to enter, modify, save, retrieve, and run SQL statements. DB-Access retains the statements, if any, in the editor. These statements are called the *current* statements.

Use the Query-language option to:

- Learn SQL and SPL.
  For example, use the Query-language option to practice the examples in the *IBM® Informix® Guide to SQL: Tutorial*.

- Create and alter table structures as an alternative to the DB-Access Schema Editor.
- Select, display, add, update, and delete data.

The SQL menu has the following options.

Option	Purpose
New	Clears current statements and positions cursor in SQL editor.

Option	Purpose
Run	Runs current SQL statements. A message is displayed or the data that is retrieved by a query is displayed with the number of rows retrieved.
Modify	Allows you to modify current SQL statements in SQL editor.
Use-editor	Starts a system editor so that you can modify current statements or create new statements. Use-editor is interchangeable with New and Modify.
Output	Redirects Run-option output to a file, printer, or system pipe.
Choose	Lists SQL command files so that you can choose a file to run or modify.
Save	Saves current SQL statements in a file for later use.
Info	Shows table information, such as columns, indexes, privileges, constraints, triggers, status, and fragmentation strategy.
Drop	Deletes a specified SQL command file.
Exit	Returns to main menu.

- SQL editor
  When you choose the New of Modify option, you see the SQL editor. You can type as many lines of text as you need. You are not limited by the size of the screen, although you might be limited by the memory constraints of your system. If you do not use the Save option to save your typed statements, they are deleted when you select an option that clears the SQL editor (such as New or Choose).
- A system editor
  When you want to enter or modify a long SQL statement or series of statements, you might prefer the flexibility and familiarity of a system editor to the SQL editor. Select the Use-editor option from the SQL menu to use the system editor.
- Statements that the Run option supports
  After you exit the editor screen, the SQL menu reopens with the Run option highlighted and the statement text is displayed in the bottom of the screen. You can run most SQL statements with the Run option.
- Redirect query results
  The output from a SELECT statement is normally displayed on the screen. You can use the Output option on the SQL menu to route query results to the printer, store them in a system file, or pipe them to a program. The Output option has the same result as the OUTPUT statement of SQL.
- Choose an existing SQL statement
  When you save SQL statements in a command file, you can retrieve the command file and run or edit the SQL statements at any time.
- Save the current SQL statement
  You can save SQL statements in a file for later use, such as to run the statements from the command line or retrieve the saved statements with the Choose option on the SQL menu.
- Support for SPL Routines
  You can create and run routines that are written in SPL from the SQL menu.
- What happens when errors occur
  If you make any syntax or typing mistakes in an SQL statement, DB-Access does not process the statement. Instead, it continues to display the text of the statement with a message that describes the error.

SQL editor

When you choose the New of Modify option, you see the SQL editor. You can type as many lines of text as you need. You are not limited by the size of the screen, although you might be limited by the memory constraints of your system. If you do not use the Save option to save your typed statements, they are deleted when you select an option that clears the SQL editor (such as New or Choose).

The SQL editor does not display more than 80 characters on a line and does not wrap lines.

- If you choose an existing command file in which the characters in a line extend beyond the 80th column, DB-Access displays a percent sign (%) in the 80th column to indicate an overflow. You cannot see all the characters beyond the percent sign, but the statement runs correctly.
- If you type characters in a new command file so that a line extends beyond the 80th column, DB-Access overwrites all the characters in the 80th column. You cannot see the overflow, and the statement does *not* run correctly.

To make the full text show on the screen, press Enter at a logical place in the first 80 characters of each line.

If you must type a quoted character string that exceeds 80 characters, such as an insert into a long CHAR column, use a system editor instead of the SQL editor.

If you want to include comments in the text:

- Use double minus signs for ANSI-compliant databases.
- Preface each comment line with a double minus sign (--) comment indicator. The comment indicator spans the entire line.
- Use braces ({ }) for databases that are not ANSI-compliant. Enclose the entire comment indicator between the braces.

A system editor

When you want to enter or modify a long SQL statement or series of statements, you might prefer the flexibility and familiarity of a system editor to the SQL editor. Select the Use-editor option from the SQL menu to use the system editor.

If you have not set the DBEDIT environment variable, you must select a text editor to use for the session. If you select Use-editor, DB-Access prompts you to accept or override the default system editor once each session.

The default editor that DB-Access displays depends on the preference that you establish for your operating system:

- Common UNIX system editors are **vi** and **ex**.
- If you use a text editor as the system default, you must save the .sql files as text.

Press RETURN to select the default editor you named after the USE-EDITOR prompt. To use a different editor, type the name of that editor and press RETURN.

Statements that the Run option supports

After you exit the editor screen, the SQL menu reopens with the Run option highlighted and the statement text is displayed in the bottom of the screen. You can run most SQL statements with the Run option.

To run statements that are not listed, use the SQL menu options New (or Use-editor) and Save to enter and save them, and then run the saved file from the command line.

The following is a list of SQL statements that you can run with the Run option.

- ALLOCATE COLLECTION
- ALLOCATE DESCRIPTOR
- ALLOCATE ROW
- ALTER ACCESS_METHOD
- ALTER FRAGMENT
- ALTER FUNCTION
- ALTER INDEX
- ALTER PROCEDURE
- ALTER ROUTINE
- ALTER SECURITY LABEL COMPONENT
- ALTER SEQUENCE

- UPDATE STATISTICS
- WHENEVER

Redirect query results

The output from a SELECT statement is normally displayed on the screen. You can use the Output option on the SQL menu to route query results to the printer, store them in a system file, or pipe them to a program. The Output option has the same result as the OUTPUT statement of SQL.

The SELECT statement must be on the screen as the current statement. Select the Output option from the SQL menu, which displays the OUTPUT menu.

You have the following output options:

- Send your query results directly to a printer. DB-Access sends the results to your default printer and displays a message on the bottom of the screen that indicates how many rows were retrieved. The query results do not show on the screen. You can set the DBPRINT environment variable to specify a default printer.
- Write query results to a new file or append the results to an existing file. If you do not specify a path when DB-Access prompts you for a file name, the file is stored in the directory that you were in when you started DB-Access.
- Send query results to a pipe. Specify a target program, such as **more**, through which to pipe output. DB-Access sends the results to that pipe.
  On UNIX systems, you must have permission to run the target program.

  On Windows systems, the **cat** utility can serve as a target program through which to pipe output.

Choose an existing SQL statement

When you save SQL statements in a command file, you can retrieve the command file and run or edit the SQL statements at any time.

Select the Choose option on the SQL menu to display the CHOOSE screen with a list of the command files that you can access. These files have the extension .sql, although the extension is not shown. For example, the following figure lists the command files that are included in the demonstration database.
Figure 1. The CHOOSE screen listing current .sql files

```
CHOOSE >>
Choose a command file with the Arrow Keys, or enter a name, then press Return.

---------------- mystores@dbserver1 ----------- Press CTRL-W for Help -------

 alt_cat              c_state             d_trig              sel_ojoin1

c_calls              c_stock             d_view              sel_ojoin2

c_cat                c_stores            del_stock           sel_ojoin3

c_custom             c_table             ins_table           sel_ojoin4

c_index              c_trig              opt_disk            sel_order

c_items              c_type              sel_agg             sel_sub

c_manuf              c_view1             sel_all             sel_union

c_orders             c_view2             sel_group           upd_table

c_proc               d_proc              sel_join
```

If no current database exists, the list includes all the command files in the current directory and in any directories that the DBPATH environment variable specifies.
Important: This list includes only those file names that have the .sql extension. If you create an SQL file outside of DB-Access and save it without the .sql extension, the files does not show in the list of files to choose.
DB-Access can only recognize files that are stored in the directory from which you started DB-Access. If the Choose command results in an empty list, and you know that you have command files, exit DB-Access, change directories to the directory that contains your .sql files, and restart DB-Access.

Save the current SQL statement

You can save SQL statements in a file for later use, such as to run the statements from the command line or retrieve the saved statements with the Choose option on the SQL menu.

To save the current SQL statement or statements in a file, select the Save option on the SQL menu. Enter a name for the command file:

- Use 1 - 10 characters. Start with a letter, then use any combination of letters, numbers, and underscores (_). Press Enter to save the file.
- UNIX: File names are case-sensitive. The file orders is not the same as Orders or ORDERS.

DB-Access appends the extension .sql to the file name. For example, if you name your file cust1, DB-Access stores the file with the name **cust1.sql**. The CHOOSE screen still lists cust1, but the operating system identifies the same file as cust1.sql if you list the directory files from the command line.

Support for SPL Routines

You can create and run routines that are written in SPL from the SQL menu.

You can store the SPL routine in a separate command file and then call it from an application or run it as a stand-alone program. After you create the SPL routine, you can run it within DB-Access with the appropriate SQL statement. The following example details the steps.

To create and run an SQL routine

1. To create the text of the routine, type directly in the NEW screen or the Use-editor screen. Enter the SPL and SQL statements for your routine in the statement block of a CREATE PROCEDURE statement.
   Use the CREATE FUNCTION statement if the routine returns values.

2. Use the Run option to create the routine and register it in the **sysprocedures** system catalog table.

3. Use the NEW screen to enter an EXECUTE PROCEDURE statement that names the routine that you want to run.
   If you use IBM® Informix® and created your routine with the CREATE FUNCTION statement, enter an EXECUTE FUNCTION statement to run the function.
4. Use the Run option to run the routine and display the results.

For example, the c_proc.sql command file, which is supplied with the demonstration database, contains an SPL. Before you can run the routine, change the word *procedure* in the c_proc.sql file to *function* because the routine returns a value. Then use the Choose option and select **c_proc**.

First you must register the routine in the database. Select the Run option, as the following figure shows.
Figure 1. Displaying the text of an SPL routine on the SQL menu

```
SQL:   New  Run   Modify  Use-editor  Output  Choose  Save  Info  Drop  Exit

Run the current SQL statements.

---------------------- mydata@mynewdb ------- Press CTRL-W for Help --------

create function read_address (lastname char(15))

        returning char(15), char(15), char(20), char(15),char(2), char(5);
        define p_fname, p_city char(15);
        define p_add char(20);
        define p_state char(2);
        define p_zip char(5);
        select fname,  address1, city, state, zipcode
                into p_fname,  p_add, p_city, p_state, p_zip
                from customer
                where lname = lastname;

        return p_fname, lastname, p_add, p_city, p_state, p_zip;

end procedure;
```

DB-Access displays a message to indicate that the database server created the routine. To run the routine, select New from the SQL menu and then enter the appropriate EXECUTE statement. In the following example, the user requests the address of a customer whose surname is Pauli:

```
EXECUTE PROCEDURE read_address ("Pauli")
```

After you enter the EXECUTE PROCEDURE or EXECUTE FUNCTION statement on the NEW screen, press Esc to return to the SQL menu. Select Run from the SQL menu to run the routine. The following figure shows the result of running the routine.
Figure 2. Result of running an SPL routine on the SQL menu

```
SQL:   New   Run   Modify  Use-editor  Output  Choose  Save  Info  Drop  Exit

Run the current SQL statements.

---------------------- mydata@mynewdb ------- Press CTRL-W for Help --------

Ludwig
Pauli
213 Erstwild Court
Sunnyvale
CA
94086
```

Tip: SPL routines are stored in the system catalog tables in executable format. Use the Routines option on the DATABASE INFO menu to display a list of the routines in the current database or to display the text of a specified routine.

What happens when errors occur

If you make any syntax or typing mistakes in an SQL statement, DB-Access does not process the statement. Instead, it continues to display the text of the statement with a message that describes the error.

If an execution or runtime error occurs, DB-Access continues to process the statement and returns an error message. For example, if you try to create a table that was already created, the following message is displayed at the bottom of the screen:

```
310: Table (mavis.mystock) already exists in database.
```

If you try to run a statement that contains more than one SQL statement, you might not see an error message immediately. If, for example, the first statement is a SELECT statement that runs correctly and the next statement contains a typing error, the data that the first statement retrieved shows on the screen before the error message is displayed for the second statement.

When DB-Access detects an error, processing stops and the Modify option on the SQL menu is highlighted. Select one of the following methods to correct the statement:

- Press Enter to choose Modify, which returns you to the SQL editor.
- Select the Use-editor option to use the default editor of your choice.

The Database option

Use the Database option to work with databases and transactions.

Use the Database option to:

- Create a database or select a database.

The database that you work with is called the *current* database.

- Retrieve and display information about a database, such as available dbspaces and the text of routines.
- Delete an existing database or close the current database.
- Commit or rollback transactions.

You can access only databases that are on the current database server. To select a database server as current, you can specify a database server when you start DB-Access, you can use the Connection menu, or you can run a CONNECT statement from the SQL menu. If you do not explicitly select a database server, DB-Access uses the default database server that the $INFORMIXSERVER environment variable specifies as the current database.

If you select or create a database when another database is already open, DB-Access closes that database before it makes your selection the current or new database.

The DATABASE menu displays the following options.

Option	Purpose
Select	Makes a database the current database
Create	Builds a new database and makes that database the current database
Info	Displays information about the current database
Drop	Removes a database from the system. You cannot delete the current database.
cLose	Closes the current database
Exit	Exits the DATABASE menu and returns you to the main menu

- List of available databases
  When you choose the Select option, the SELECT DATABASE screen opens. The first database in the list of available databases is highlighted, accompanied by the names of database servers.
- Retrieve nondefault locale information
  Globalization affects the order in which lists are displayed in DB-Access. Globalization enables the display and appropriate ordering of non-English-language data. Informix® supports globalization with Global Language Support (GLS) locales. Earlier database server versions used Native Language Support (NLS) for this purpose.
- Close a database
  To close the current database, use the cLose option from the DATABASE menu.

List of available databases

When you choose the Select option, the SELECT DATABASE screen opens. The first database in the list of available databases is highlighted, accompanied by the names of database servers.

The list is organized alphabetically by database server and then by database for each database server. You can display a maximum of 512 database names on the SELECT DATABASE screen.

Important: In the SELECT DATABASE screen, the names of databases are limited to 18 characters. If a database name is longer than 18 characters, you see the first 17 characters of the name followed by a '+' sign. Enter a '+' sign to display the complete long name in **vi**. To exit from **vi**, press `ESC ZZ`.
The list of available databases that is displayed depends on two factors:

- The settings of certain environment variables.
  - If you use one database server, DB-Access displays the names of all databases on the current database server and in your DBPATH setting.
  - If you use multiple database servers, the ONCONFIG environment variable determines the current database server.
- The current connection. For example:
  - If no explicit connection exists, DB-Access displays the databases in the DBPATH setting.
  - If a current explicit connection exists, all databases in the DBPATH setting that pertain to the current database server are displayed.

Retrieve nondefault locale information

Globalization affects the order in which lists are displayed in DB-Access. Globalization enables the display and appropriate ordering of non-English-language data. Informix® supports globalization with Global Language Support (GLS) locales. Earlier database server versions used Native Language Support (NLS) for this purpose.

If the current database supports globalization, you can select the Nls option on the DATABASE INFO menu to display information about collating sequence and C CType (character classification type), as the following figure shows.
Figure 1. The DATABASE INFO menu with globalization information displayed

```
DATABASE INFO:  dBspace   Nls   Routine  Databases  Exit
Display NLS information for a database.

-------------- - database_demo ------------ Press CTRL-W for Help --------

fr_fr.8859-1 Collating Sequence
CType
```

DB-Access does not provide an option on the DATABASE INFO menu for displaying the GLS collating sequence and character classification type. To obtain information about the GLS locale that is enabled for your database server, enter the following query with the SQL editor:

```
SELECT tabname, site FROM systables
WHERE tabid = 90 OR tabid = 91
```

The row with tabid 90 stores the COLLATION category of the database locale. The row with tabid 91 stores the CTYPE category of the database locale. The following figure shows the result of the preceding query for the default US English locale.
Figure 2. Retrieving GLS information

```
SQL:   New  Run   Modify  Use-editor  Output  Choose  Save  Info  Drop  Exit
Run the current SQL statements.

For further information about the COLLATION and CTYPE categories in a GLS locale file, see the *IBM® Informix GLS User's Guide*.

Close a database

To close the current database, use the cLose option from the DATABASE menu.

If you begin a transaction but do not commit it or roll it back, and then you try to close a database with transactions, the TRANSACTION menu opens. The TRANSACTION menu ensures that you either commit or roll back an active transaction before you close the current database.
Important: Select an option carefully. You might commit transactions that you do not want if you select Commit, and you do lose any new transactions if you select Rollback.
The TRANSACTION menu also opens whenever you attempt to open a new database or try to leave the DB-Access menu system without first terminating a transaction.

Important: If you begin a transaction in an ANSI-compliant database but do not issue a COMMIT statement or ROLLBACK statement, then try to close the database using a non-menu mode, DB-Access commits the transaction for you. If you do not want to commit the transaction, issue both a ROLLBACK statement and a CLOSE DATABASE statement from the command line.

The Table option

Use the Table option to work with tables.

Use the Table option to perform any of the following table management tasks without SQL programming:

- Create a new table
- Define fragmentation strategy for a new or existing table
- Alter, delete, or display information about an existing table

Use the TABLE menu options as the following table shows.

Option	Purpose
Create	Enables you to define the structure of a new table. The CREATE TABLE menu provides data type options for built-in data types. To define a column with one of the extended data types, such as smart large objects, user-defined (opaque) data types, or a collection data type, use the SQL menu to enter and run a CREATE TABLE statement. DB-Access can construct only a nonclustered, ascending B-tree column index. If you want hash or hybrid fragmentation, use the SQL menu to enter and run the CREATE TABLE or ALTER TABLE statement.
Alter	Enables you to alter the structure of an existing table, including columns, fragmentation, and constraints. You must have the Alter privilege to successfully alter a table. Note: If you use the UI to build the SQL statements to Alter a table without the Alter privilege, the table will be locked and the operation will fail. Further, the lock will be held until you exit the alter menu. To use the LOAD statement to insert data into a table, you must have both Insert and Select privileges for the table.
Info	Displays information about the structure of a table
Drop	Deletes a table from the database
Move	Moves a table from the current database to another database.
Exit	Returns to the DB-Access main menu

Both the CREATE TABLE and ALTER TABLE menus have the same options, which are described in the following table.

Option	Purpose
Add	Displays the Schema Editor, from which you can add a new column to the table
Modify	Displays the columns that you defined with the Add option so that you can modify the column structure before building the table
Drop	Drops an existing column from the table
Screen	Displays the next screen of column definitions in the Schema Editor
Table_options	Enables you to display and select storage spaces for a new table. Displays choices from which to set a fragmentation strategy for a new table. Enables you to set extent sizes and lock mode for a new table. Adds or deletes rowids for an existing fragmented table.
Constraints	Enables you to define primary-key, foreign-key, check, and unique constraints, and to set default column values

Option	Purpose
Exit	Builds, rebuilds, or discards the schema and structure that you specified with the other options, and then returns to the TABLE menu

Important: You must use the SPACEBAR to move between menu options, because the arrow keys control cursor movement in the Schema Editor.

- Display table information
  Use the Info option on the TABLE menu to display information about the structure of a table.

Display table information

Use the Info option on the TABLE menu to display information about the structure of a table.

Note the following items:

- If you are not the table owner, the table name is prefixed by the owner name, as in **june.clients**.
- If the list of tables does not fit on one screen, the last entry is an ellipsis (...). Use the arrow keys to highlight the ellipsis, and the next page of table names are displayed.
- If globalization is enabled, the list of table names is sorted according to the database collation rules defined when the database was created. Thus, different users using different collating sequences for DB-Access see the table names in the database listed in the same order.

To request information about tables on a different database server, use the format *database*@*server*:*table* or *database*@*server*:*owner*.*table* at the prompt. The following example requests information about the **customer** table that **dba** created in the **accounts** database on the database server **topend**:

```
INFO FOR TABLE >> accounts@topend:dba.customer
```

The INFO menu has the following options.

Option	Purpose
Columns	Lists data type by column name and indicates which columns can contain a null value
Indexes	Describes each index that is defined for a specified table
Privileges	Lists the users who have Select, Update, Insert, Delete, Index, or Alter privileges for the specified table
References	Lists the users who have the table-level References privilege for the specified table and the names of the columns they can reference
Status	Lists the table name, owner, row size, number of rows and columns, and creation date of the current table
cOnstraints	Displays the referential, primary, unique, and check constraints, and the default values for the columns in the specified table
triGgers	Displays header and body information for a specified trigger
Table	Redisplays the INFO FOR TABLE menu so that you can select a different table for examination
Fragments	Lists fragmented dbspaces assigned to the table and, for expression-based fragmentation, displays the expression that is assigned to each dbspace
Exit	Returns to the TABLE menu

Tip: From the CREATE TABLE menu, use Table-options to view extent and lock mode information, or issue a SELECT statement to list the table description in the **systables** system catalog table.

The Connection and Session options

Use the Connection option if you want to connect to a specific database server and database or explicitly disconnect from the current database environment. Use the Session option to display information about the current DB-Access session.

For the globalization considerations that apply to establishing a connection between a client application, such as DB-Access, and a database, see the *IBM Informix GLS User's Guide*. The database server examines the client locale information passed by the client, verifies the database locale, and determines the server-processing locale for transferring data between the client and the database.

You can use the Secure Sockets Layer (SSL) protocol, a communication protocol that ensures privacy and integrity of data that is transmitted over the network, for DB-Access connections with IBM® Informix®. For information about the SSL protocol, see Secure sockets layer protocol.

On Windows, if you specify a user identifier but no domain name for a connection to a machine that expects both a domain name and a user name (*domain\user*), DB-Access checks only the local machine and the primary domain for the user account. If you explicitly specify a domain name, that domain is used to search for the user account. The attempted connection fails with error -951 if no matching *domain\user* account is found on the local machine.

The CONNECTION menu displays the following options.

Option	Purpose
Connect	Connects to a database environment. To access a specific database, you must have permission.
Disconnect	Disconnects from the current database environment
Exit	Returns to the DB-Access main menu

When you use the Connect option, the SELECT DATABASE screen alphabetically lists all available databases on the specified database server. The database list on the SELECT DATABASE screen depends on the current connection. For example:

- If no current connection exists or the current connection is an implicit default connection, all the databases that are listed in the DBPATH environment variable setting are displayed.
- If a current explicit connection exists, all the databases in the DBPATH that pertain to the current server are displayed.

- Implicit closures
  DB-Access closes any open connections or databases when you connect to a new environment.

Implicit closures

DB-Access closes any open connections or databases when you connect to a new environment.

DB-Access closes any open connections or databases in the following situations:

- When you connect to a new database environment without explicitly disconnecting from the current one, DB-Access performs an implicit disconnect and the database closes.
- When you connect to a *database*@*server* and then close the database, the database server remains connected.
- When you connect to a database server, open a database, and then close the database, the database server remains connected.
- If you open a database and then try to connect to a database server, DB-Access performs an implicit disconnect and closes the database.
  Only one connection is allowed. You must disconnect from the database server associated with the open database or close the database before you can connect to another database server.

If DB-Access must close a database that still has outstanding transactions, it prompts you to commit or roll back those transactions.

Appendixes

- How to read online help for SQL statements
  Specific conventions are used to represent the syntax of SQL statements in DB-Access online help screens.
- Demonstration SQL
  Various command files that are available with DB-Access.

How to read online help for SQL statements

Specific conventions are used to represent the syntax of SQL statements in DB-Access online help screens.

You can request online help for SQL statements in either of the following ways:

- Highlight the New, Modify, or Use-editor options on the SQL menu and press CTRL-W.
- Press CTRL-W while you are on the NEW or MODIFY screens of the SQL menu.

The form of the syntax diagrams that shows when you request online Help for SQL statements in DB-Access is different from the syntax diagrams in the *IBM® Informix® Guide to SQL: Syntax*.

The conventions and rules governing SQL statement syntax in DB-Access online help screens are described in the following list.

ABC
: Any term in an SQL statement that is displayed in uppercase letters is a keyword. Type keywords exactly, disregarding case, as shown in the following example:

  ```
  CREATE SYNONYM synonym-name
  ```

  This syntax indicates you must type the keywords CREATE SYNONYM or create synonym without adding or deleting spaces or letters.

abc
: Substitute a value for any term that is displayed in lowercase letters. In the previous example, substitute a value for synonym-name.

( )
: Type any parentheses as shown. They are part of the syntax of an SQL statement and are not special symbols.

[ ]
: Do not type brackets as part of a statement. They surround any part of a statement that is optional. For example:

  ```
  CREATE [TEMP] TABLE
  ```

  This syntax indicates that you can type either CREATE TABLE or CREATE TEMP TABLE.

|
: The vertical bar indicates a choice among several options. For example:

  ```
  [VANILLA | CHOCOLATE [MINT] | STRAWBERRY]
  ```

  This syntax indicates that you can enter either VANILLA, CHOCOLATE, or STRAWBERRY and that, if you enter CHOCOLATE, you can also enter MINT.

{ }
: When you must choose only one of several options, the options are enclosed in braces and are separated by vertical bars. For example:

  ```
  {GUAVA | MANGO | PASSIONFRUIT}
  ```

  This syntax indicates that you must enter either GUAVA, MANGO, or PASSIONFRUIT, but you cannot enter more than one choice.

...
: An ellipsis indicates that you can enter an indefinite number of additional items, such as the one immediately preceding the ellipsis. For example:

```
old-column-name
...
```

This syntax indicates that you can enter a series of existing column names after the first one.

The *IBM Informix Guide to SQL: Syntax* contains more detailed syntax diagrams and instructions for interpreting the diagram format that is used in the publication.

Demonstration SQL

Various command files that are available with DB-Access.

The command files all have the extension .sql when displayed from the command line but are displayed without the extension on the SQL CHOOSE menu.

Keywords in these command files are shown in uppercase letters to make the SQL statements easier to read. Keywords in the actual command files are lowercase.
Important: Although the command files are listed alphabetically in this appendix, you cannot run the command files that create tables in that order without causing errors. The order in which the tables are created is important because of the referential constraints that link those tables.
When you select the Choose option on the SQL menu, the CHOOSE screen opens. The screen shows a list of the command files that you can access, similar to the display that the following figure shows. These files are included with the **stores_demo** database. Other .sql files are described later in this appendix.

Figure 1. Command files listed on the CHOOSE screen

```
CHOOSE >>
Choose a command file with the Arrow Keys, or enter a name, then press Return.

----------------- stores_demo @dbserver1 -------------- Press CTRL-W for Help ------

alt_cat             c_state             d_trig              sel_ojoin1

c_calls             c_stock             d_view              sel_ojoin2

c_cat               c_stores_demo       del_stock           sel_ojoin3

c_custom            c_table             ins_table           sel_ojoin4

c_index             c_trig              opt_disk            sel_order

c_items             c_type              sel_agg             sel_sub

c_manuf             c_view1             sel_all             sel_union

c_orders            c_view2             sel_group           upd_table

c_proc              d_proc              sel_join
```

If you do not see the command files included with your demonstration database, check the following:

- Did you copy the demonstration SQL command files to your current directory when you ran the demonstration database initialization script? If not, you can rerun the initialization script to copy them.
- Did you start DB-Access from the directory in which you installed the demonstration SQL command files? If not, exit DB-Access, change to the appropriate directory, and start DB-Access again.

For instructions about running the initialization script, copying command files, and starting DB-Access, seedbaccess command: Start DB-Access.

Use these command files with DB-Access for practice with SQL and the demonstration database. You can rerun the demonstration database initialization script whenever you want to refresh the database tables and SQL files.

- SQL files for the relational database model
  You can run sample SQL command files on the **stores_demo** demonstration database.
- SQL files for the Dimensional Database Model
  You can implement a dimensional database for data-warehousing applications by running scripts that create the **sales_demo** database.
- User-defined routines for the object-relational database model
  You can run sample user-defined routines on the **superstores_demo** database.

SQL files for the relational database model

You can run sample SQL command files on the **stores_demo** demonstration database.

- The alt_cat.sql command file
- The c_calls.sql command file
- The c_cat.sql command file
- The c_custom.sql command file
- The c_index.sql command file
- The c_items.sql command file
- The c_manuf.sql command file
- The c_orders.sql file
- The c_proc.sql command file
- The c_state command file
- The c_stock.sql command file
- The c_stores.sql command file
- The c_table.sql command file
- The c_trig.sql command file

Related information:
The stores_demo Database

The alt_cat.sql command file

The following command file alters the **catalog** table. It drops the existing constraint **aa** on the **catalog** table and adds a new constraint, **ab**, which specifies cascading deletes. You can use this command file and then the del_stock.sql command file for practice with cascading deletes on a database with logging.

```
ALTER TABLE catalog DROP CONSTRAINT aa;

ALTER TABLE catalog ADD CONSTRAINT
   (FOREIGN KEY (stock_num, manu_code) REFERENCES stock
    ON DELETE CASCADE CONSTRAINT ab);
```

The c_calls.sql command file

The following command file creates the **cust_calls** table:

```
CREATE TABLE cust_calls
   (
   customer_num          INTEGER,
   call_dtime            DATETIME YEAR TO MINUTE,
   user_id               CHAR(18) DEFAULT USER,
   call_code             CHAR(1),
   call_descr            CHAR(240),
   res_dtime             DATETIME YEAR TO MINUTE,
   res_descr             CHAR(240),
   PRIMARY KEY (customer_num, call_dtime),
   FOREIGN KEY (customer_num) REFERENCES customer (customer_num),
   FOREIGN KEY (call_code) REFERENCES call_type (call_code)
   );
```

The c_cat.sql command file

The following command file creates the **catalog** table. It contains a constraint, **aa**, which allows you to practice with cascading deletes by running the SQL statements in the alt_cat.sql and del_stock.sql command files on a database with logging.

```
CREATE TABLE catalog
   (
   catalog_num      SERIAL(10001),
   stock_num        SMALLINT NOT NULL,
   manu_code        CHAR(3) NOT NULL,
   cat_descr        TEXT,
   cat_picture      BYTE,
   cat_advert       VARCHAR(255, 65),
   PRIMARY KEY (catalog_num),
   FOREIGN KEY (stock_num, manu_code) REFERENCES stock
      CONSTRAINT aa
   );
```

The c_custom.sql command file

The following command file creates the **customer** table:

```
CREATE TABLE customer
   (
   customer_num       SERIAL(101),
   fname              CHAR(15),
   lname              CHAR(15),
   company            CHAR(20),
   address1           CHAR(20),
   address2           CHAR(20),
   city               CHAR(15),
   state              CHAR(2),
   zipcode            CHAR(5),
   phone              CHAR(18),
   PRIMARY KEY (customer_num)
   );
```

The c_index.sql command file

The following command file creates an index on the **zipcode** column of the **customer** table:

```
CREATE INDEX zip_ix ON customer (zipcode);
```

The c_items.sql command file

The following command file creates the **items** table:

```
CREATE TABLE items
   (
   item_num           SMALLINT,
   order_num          INTEGER,
   stock_num          SMALLINT NOT NULL,
   manu_code          CHAR(3) NOT NULL,
   quantity           SMALLINT CHECK (quantity >= 1),
   total_price        MONEY(8),
   PRIMARY KEY (item_num, order_num),
   FOREIGN KEY (order_num) REFERENCES orders (order_num),
   FOREIGN KEY (stock_num, manu_code) REFERENCES stock
      (stock_num, manu_code)
   );
```

The c_manuf.sql command file

The following command file creates the **manufact** table:

```
CREATE TABLE manufact
   (
   manu_code               CHAR(3),
   manu_name               CHAR(15),
   lead_time               INTERVAL DAY(3) TO DAY,
   PRIMARY KEY (manu_code)
   );
```

The c_orders.sql file

The following command file creates the **orders** table:

```
CREATE TABLE orders
   (
   order_num            SERIAL(1001),
   order_date           DATE,
   customer_num         INTEGER NOT NULL,
   ship_instruct        CHAR(40),
   backlog              CHAR(1),
   po_num               CHAR(10),
   ship_date            DATE,
   ship_weight          DECIMAL(8,2),
   ship_charge          MONEY(6),
   paid_date            DATE,
   PRIMARY KEY (order_num),
   FOREIGN KEY (customer_num) REFERENCES customer (customer_num)
   );
```

The c_proc.sql command file

The following command file creates an SPL routine. It reads the full name and address of a customer and takes a last name as its only argument.

This routine shows the legacy use of CREATE PROCEDURE.

To conform with the SQL standard preferred with IBM® Informix®, define a *function* if you want to return values from a routine.

```
CREATE PROCEDURE read_address (lastname CHAR(15))
   RETURNING CHAR(15), CHAR(15), CHAR(20), CHAR(15), CHAR(2), CHAR(5);
   DEFINE p_fname, p_city CHAR(15);
   DEFINE p_add CHAR(20);
   DEFINE p_state CHAR(2);
   DEFINE p_zip CHAR(5);
   SELECT fname, address1, city, state, zipcode
      INTO p_fname,  p_add, p_city, p_state, p_zip
      FROM customer
      WHERE lname = lastname;

   RETURN p_fname, lastname, p_add, p_city, p_state, p_zip;

END PROCEDURE;
```

The c_state command file

The following command file creates the **state** table:

```
CREATE TABLE state
   (
   code                CHAR(2),
   sname               CHAR(15),
   PRIMARY KEY (code)
   );
```

The c_stock.sql command file

The following command file creates the **stock** table:

```
CREATE TABLE stock
   (
   stock_num           SMALLINT,
   manu_code           CHAR(3),
   description         CHAR(15),
   unit_price          MONEY(6),
   unit                CHAR(4),
   unit_descr          CHAR(15),
   PRIMARY KEY (stock_num, manu_code),
   FOREIGN KEY (manu_code) REFERENCES manufact
   );
```

The c_stores.sql command file

The following command file creates the **stores_demo** database:

```
CREATE DATABASE stores_demo;
```

The c_table.sql command file

The following command file creates a database named **restock** and then creates a custom table named **sports** in that database:

```
CREATE DATABASE restock;

CREATE TABLE sports
   (
   catalog_no          SERIAL UNIQUE,
   stock_no            SMALLINT,
   mfg_code            CHAR(5),
   mfg_name            CHAR(20),
   phone               CHAR(18),
   descript            VARCHAR(255)
   );
```

The c_trig.sql command file

The following command file creates a table named **log_record** and then creates a trigger named **upqty_i**, which updates it:

```
CREATE TABLE log_record
   (item_num    SMALLINT,
   ord_num      INTEGER,
   username     CHARACTER(8),
   update_time  DATETIME YEAR TO MINUTE,
   old_qty      SMALLINT,
```

```
   new_qty      SMALLINT);

CREATE TRIGGER upqty_i
UPDATE OF quantity ON items
REFERENCING OLD AS pre_upd
        NEW AS post_upd
FOR EACH ROW(INSERT INTO log_record
   VALUES (pre_upd.item_num, pre_upd.order_num, USER, CURRENT,
         pre_upd.quantity, post_upd.quantity));
```

The c_type.sql command file

The following command file creates the **call_type** table:

```
CREATE TABLE call_type
   (
   call_code               CHAR(1),
   code_descr              CHAR(30),
   PRIMARY KEY (call_code)
   );
```

The c_view1.sql command file

The following command file creates a view called **custview** on a single table and grants privileges on the view to **public**. It includes the WITH CHECK OPTION keywords to verify that any changes made to underlying tables through the view do not violate the definition of the view.

```
CREATE VIEW custview (firstname, lastname, company, city) AS
   SELECT fname, lname, company, city
      FROM customer
      WHERE city = 'Redwood City'
      WITH CHECK OPTION;

GRANT DELETE, INSERT, SELECT, UPDATE
   ON custview
   TO public;
```

The c_view2.sql command file

The following command file creates a view on the **orders** and **items** tables:

```
CREATE VIEW someorders (custnum,ocustnum,newprice) AS
   SELECT orders.order_num, items.order_num,
         items.total_price*1.5
      FROM orders, items
      WHERE orders.order_num = items.order_num
      AND items.total_price > 100.00;
```

The d_proc.sql command file

The following command file drops the SPL routine that the c_proc.sql command file created:

```
DROP PROCEDURE read_address;
```

The d_trig.sql command file

The following command file drops the trigger that the c_trig.sql command file created:

```
DROP TRIGGER upqty_i;
```

The d_view.sql command file

The following command file drops the view named **custview** that the c_view1.sql command file created:

```
DROP VIEW custview;
```

The del_stock.sql command file

The following command file deletes rows from the **stock** table where the stock number is 102. This delete will cascade to the **catalog** table (although the related manufacturer codes will remain in the **manufact** table). The del_stock.sql command file can be used following the alt_cat.sql command file for practice with cascading deletes on a database with logging.

```
DELETE FROM stock WHERE stock_num = 102;
```

After running the SQL statements in the alt_cat.sql and del_stock.sql command files, issue the following query on the **catalog** table to verify that the rows were deleted:

```
SELECT * FROM catalog WHERE stock_num = 102;
```

The **stores_demo** database has been changed. You might want to rerun the **dbaccessdemo** script to rebuild the original database.

The ins_table.sql command file

The following command file inserts one row into the **sports** table that the c_table.sql command file created:

```
INSERT INTO sports
   VALUES (0,18,'PARKR', 'Parker Products', '503-555-1212',
   'Heavy-weight cotton canvas gi, designed for aikido or
   judo but suitable for karate. Quilted top with side ties,
   drawstring waist on pants. White with white belt.
   Pre-washed for minimum shrinkage. Sizes 3-6.');
```

The sel_agg.sql command file

The SELECT statement in the following command file queries on table data using aggregate functions. It combines the aggregate functions MAX and MIN in a single statement.

```
SELECT MAX (ship_charge), MIN (ship_charge)
   FROM orders;
```

The sel_all.sql command file

The following example command file contains all seven SELECT statement clauses that you can use in the IBM® Informix® implementation of interactive SQL. This SELECT statement joins the **orders** and **items** tables. It also uses display labels, table aliases, and integers as column indicators; groups and orders the data; and puts the results into a temporary table.

```
SELECT o.order_num, SUM (i.total_price) price,
     paid_date - order_date span
   FROM orders o, items i
   WHERE o.order_date > '01/01/90'
      AND o.customer_num > 110
      AND o.order_num = i.order_num
   GROUP BY 1, 3
   HAVING COUNT (*) < 5
   ORDER BY 3
   INTO TEMP temptab1;
```

The sel_group.sql command file

The following example command file includes the GROUP BY and HAVING clauses. The HAVING clause usually complements a GROUP BY clause by applying one or more qualifying conditions to groups after they are formed, which is similar to the way the WHERE clause qualifies individual rows. (One advantage to using a HAVING clause is that you can include aggregates in the search condition; you cannot include aggregates in the search condition of a WHERE clause.)

Each HAVING clause compares one column or aggregate expression of the group with another aggregate expression of the group or with a constant. You can use the HAVING clause to place conditions on both column values and aggregate values in the group list.

```
SELECT order_num, COUNT(*) number, AVG (total_price) average
   FROM items
   GROUP BY order_num
   HAVING COUNT(*) > 2;
```

The sel_join.sql command file

The following example command file uses a simple join on the **customer** and **cust_calls** tables. This query returns only those rows that show the customer has made a call to customer service.

```
SELECT c.customer_num, c.lname, c.company,
     c.phone, u.call_dtime, u.call_descr
   FROM customer c, cust_calls u
   WHERE c.customer_num = u.customer_num;
```

The sel_ojoin1.sql command file

The following example command file uses a simple outer join on two tables. The use of the keyword OUTER in front of the **cust_calls** table makes it the subservient table. An outer join causes the query to return information about all customers, even if they do not make calls to customer service. All rows from the dominant **customer** table are retrieved, and null values are assigned to corresponding rows from the subservient **cust_calls** table.

```
SELECT c.customer_num, c.lname, c.company,
     c.phone, u.call_dtime, u.call_descr
   FROM customer c, OUTER cust_calls u
   WHERE c.customer_num = u.customer_num;
```

The sel_ojoin2.sql command file

The following example command file creates an outer join, which is the result of a simple join to a third table. This second type of outer join is called a *nested simple join*.

This query first performs a simple join on the **orders** and **items** tables, retrieving information about all orders for items with a **manu_code** of KAR or SHM. It then performs an outer join, which combines this information with data from the dominant **customer** table. An optional ORDER BY clause reorganizes the data.

```
SELECT c.customer_num, c.lname, o.order_num,
     i.stock_num, i.manu_code, i.quantity
   FROM customer c, OUTER (orders o, items i)
   WHERE c.customer_num = o.customer_num
      AND o.order_num = i.order_num
      AND manu_code IN ('KAR', 'SHM')
   ORDER BY lname;
```

The sel_ojoin3.sql command file

The following example SELECT statement is the third type of outer join, known as a *nested outer join*. It queries on table data by creating an outer join, which is the result of an outer join to a third table.

This query first performs an outer join on the **orders** and **items** tables, retrieving information about all orders for items with a **manu_code** of KAR or SHM. It then performs an outer join, which combines this information with data from the dominant **customer** table. This query preserves order numbers that the previous example eliminated, returning rows for orders that do not contain items with either manufacturer code. An optional ORDER BY clause reorganizes the data.

```
SELECT c.customer_num, lname, o.order_num,
     stock_num, manu_code, quantity
   FROM customer c, OUTER (orders o, OUTER items i)
   WHERE c.customer_num = o.customer_num
      AND o.order_num = i.order_num
      AND manu_code IN ('KAR', 'SHM')
   ORDER BY lname;
```

The sel_ojoin4.sql command file

The following example queries on table data using the fourth type of outer join. This query shows an outer join, which is the result of an outer join of each of two tables to a third table. In this type of outer join, join relationships are possible *only* between the dominant table and subservient tables.

This query individually joins the subservient tables **orders** and **cust_calls** to the dominant **customer** table but does not join the two subservient tables. (An INTO TEMP clause selects the results into a temporary table.)

```
SELECT c.customer_num, lname, o.order_num,
     order_date, call_dtime
   FROM customer c, OUTER orders o, OUTER cust_calls x
   WHERE c.customer_num = o.customer_num
      AND c.customer_num = x.customer_num
   INTO temp service;
```

The sel_order.sql command file

The following example uses the ORDER BY and WHERE clauses to query. In this SELECT statement, the comparison 'bicycle%' (LIKE condition, or 'bicycle*' for a MATCHES condition) specifies the letters bicycle followed by any sequence of zero or more characters. It narrows the search further by adding another comparison condition that excludes a **manu_code** of PRC.

```
SELECT * FROM stock
   WHERE description LIKE 'bicycle%'
      AND manu_code NOT LIKE 'PRC'
   ORDER BY description, manu_code;
```

The sel_sub.sql command file

The following example uses a subquery to query. This self-join uses a correlated subquery to retrieve and list the 10 highest-priced items ordered.

```
SELECT order_num, total_price
   FROM items a
   WHERE 10 >
      (SELECT COUNT (*)
         FROM items b
         WHERE b.total_price < a.total_price)
   ORDER BY total_price;
```

The sel_union.sql command file

The following example uses the UNION clause to query on data in two tables. The compound query performs a union on the **stock_num** and **manu_code** columns in the **stock** and **items** tables. The statement selects items that have a unit price of less than $25.00 or that have been ordered in quantities greater than three, and it lists their **stock_num** and **manu_code**.

```
SELECT DISTINCT stock_num, manu_code
   FROM stock
   WHERE unit_price < 25.00

UNION

SELECT stock_num, manu_code
   FROM items
   WHERE quantity > 3;
```

The upd_table.sql command file

The following example updates the **sports** table that the c_table.sql command file created:

```
UPDATE sports
   SET phone = '808-555-1212'
   WHERE mfg_code = 'PARKR';
```

SQL files for the Dimensional Database Model

You can implement a dimensional database for data-warehousing applications by running scripts that create the **sales_demo** database.

The **sales_demo** database is based on the **stores_demo** schema and data.

To create the **sales_demo** database:

1. Create a **stores_demo** database with the following command:

   ```
   dbaccessdemo -log
   ```

2. Make sure that the createdw.sql and loaddw.sql files are in the same directory as the files with extension .unl that the loaddw.sql uses.
3. Run the createdw.sql file.
4. Run the loaddw.sql file.

- The createdw.sql file
- The loaddw.sql file

The createdw.sql file

This file creates the new **sales_demo** database with logging and then creates tables within that database. It contains the following statements:

```
create database sales_demo with log;

create table product (
   product_code integer,
   product_name char(31),
   vendor_code char(3),
   vendor_name char(15),
   product_line_code smallint,
   product_line_name char(15));

create table customer (
   customer_code integer,
   customer_name char(31),
   company_name char(20));

create table sales (
   customer_code integer,
   district_code smallint,
   time_code integer,
   product_code integer,
```

```
   units_sold smallint,
   revenue money (8,2),
   cost money (8,2),
   net_profit money(8,2));

create table time
   (
   time_code int,
   order_date date,
   month_code smallint,
   month_name char(10),
   quarter_code smallint,
   quarter_name char(10),
   year integer
   );

create table geography (
    district_code serial,
   district_name char(15),
   state_code char(2),
   state_name char(18),
   region smallint);
```

The loaddw.sql file

This file contains the commands necessary to load data from two sources:

- The files with the extension .unl in your demonstration directory
- Data selected from the **stores_demo** database

These SQL statements in loaddw.sql accomplish these actions:

```
connect to "stores_demo ";
load from "add_orders.unl"
   insert into stores_demo :orders;
load from 'add_items.unl'
   insert into stores_demo :items;

connect to "sales_demo";
load from 'costs.unl'
   insert into cost;
load from 'time.unl'
   insert into time;

insert into geography(district_name, state_code, state_name)
   select distinct c.city, s.code, s.sname
from stores_demo :customer c, stores_demo :state s
   where c.state = s.code;
update geography      -- converts state_code values to region values
   set region = 1
   where state_code = "CA";
update geography
   set region = 2
   where state_code <> "CA";

insert into customer (customer_code, customer_name, company_name)
   select c.customer_num, trim(c.fname) || " " || c.lname, c.company
   from stores_demo :customer c;

insert into product (product_code, product_name, vendor_code,
   vendor_name, product_line_code, product_line_name)
 select a.catalog_num,
      trim(m.manu_name) || " "|| s.description,
      m.manu_code, m.manu_name, s.stock_num, s.description
   from stores_demo :catalog a, stores_demo :manufact m,
      stores_demo :stock s
   where a.stock_num = s.stock_num and
      a.manu_code = s.manu_code and
       s.manu_code = m.manu_code;
insert into sales (customer_code, district_code,
   time_code, product_code,
   units_sold, revenue, cost, net_profit)
   select c.customer_num, g.district_code, t.time_code, p.product_code,
   SUM(i.quantity), SUM(i.total_price),
   SUM(i.quantity * x.cost),
   SUM(i.total_price) - SUM(i.quantity * x.cost)
   from stores_demo :customer c, geography g, time t,
       product p,
      stores_demo :items i, stores_demo :orders o, cost x
    where c.customer_num = o.customer_num and
       o.order_num = i.order_num and
       p.product_line_code = i.stock_num and
      p.vendor_code = i.manu_code and
      t.order_date = o.order_date and
      p.product_code = x.product_code and
      c.city = g.district_name
      GROUP BY 1,2,3,4;

connect to "stores_demo ";
load from 'add_orders.unl'
   insert into stores_demo :orders;
```

```
load from 'add_items.unl'
   insert into stores_demo :items;

connect to "sales_demo";
load from 'costs.unl'
   insert into cost;
load from 'time.unl'
   insert into time;

insert into geography(district_name, state_code, state_name)
   select distinct c.city, s.code, s.sname
from stores_demo :customer c, stores_demo :state s
   where c.state = s.code;
update geography      -- converts state_code values to region values
   set region = 1
   where state_code = "CA";
update geography
   set region = 2
   where state_code <> "CA";

insert into customer (customer_code, customer_name, company_name)
   select c.customer_num, trim(c.fname) || " " || c.lname, c.company
   from stores_demo :customer c;

insert into product (product_code, product_name, vendor_code,
   vendor_name, product_line_code, product_line_name)
 select a.catalog_num,
      trim(m.manu_name) || " " || s.description,
      m.manu_code, m.manu_name, s.stock_num, s.description
   from stores_demo :catalog a, stores_demo :manufact m,
      stores_demo :stock s
   where a.stock_num = s.stock_num and
      a.manu_code = s.manu_code and
       s.manu_code = m.manu_code;

insert into sales (customer_code, district_code,
   time_code, product_code,
   units_sold, revenue, cost, net_profit)
   select c.customer_num, g.district_code, t.time_code, p.product_code,
   SUM(i.quantity), SUM(i.total_price),
   SUM(i.quantity * x.cost),
   SUM(i.total_price) - SUM(i.quantity * x.cost)
   from stores_demo :customer c, geography g, time t, product p,
      stores_demo :items i, stores_demo :orders o, cost x
    where c.customer_num = o.customer_num and
       o.order_num = i.order_num and
       p.product_line_code = i.stock_num and
      p.vendor_code = i.manu_code and
      t.order_date = o.order_date and
      p.product_code = x.product_code and
      c.city = g.district_name
      GROUP BY 1,2,3,4;
```

User-defined routines for the object-relational database model

You can run sample user-defined routines on the **superstores_demo** database.

The **superstores_demo** database does not replace the **stores_demo** database. Both databases are available. The **superstores_demo** database schema is not compatible with earlier versions with **stores_demo**. In many cases, you cannot use test queries developed for **stores_demo** against the tables of **superstores_demo** because the tables differ.

No SQL command files are associated specifically with **superstores_demo**. However, there are user-defined routines that you can run in the SQL editor or a system editor.

The **superstores_demo** database includes examples of the following features:

- Collection types: SET, LIST
- Named row types: location_t, loc_us_t, loc_non_us_t
- Unnamed row types
- Type and table inheritance
- Built-in data types: BOOLEAN, SERIAL8, INT8
- Distinct data type: percent
- Smart large objects: BLOB and CLOB

The **superstores_demo** database has row types and tables to support the following table-inheritance hierarchies:

- customer/retail_customer
- customer/whlsale_customer
- location/location_us
- location/location_non_us

For more information about user-defined routines, see *IBM® Informix® User-Defined Routines and Data Types Developer's Guide*.

High-Performance Loader User's Guide

These topics describe how to use the IBM® Informix® High-Performance Loader (HPL) to load and unload large quantities of data efficiently to or from databases.

These topics describe:

- The architecture of HPL
- The **onpload** utility that allows you to control HPL from a script.
- The onpload database that maintains information about load and unload jobs that you have prepared.
- The **ipload** graphical user interface (GUI).
- The **onpladm** utility.

The **ipload** utility is a UNIX application that helps users prepare load and unload jobs for both UNIX and Windows. The **onpladm** utility is a command-line version of the **ipload** utility that operates on both UNIX and Windows.

The first section introduces the HPL, provides a general overview of the tasks that the HPL performs, describes the architecture of the HPL, and includes two tutorial examples that take you through the process of loading and unloading data.

The second section introduces the **ipload** utility, a graphical user interface that you can use to set the parameters for the HPL.

Subsequent sections give details about developing the onpload database by using the individual components of the **ipload**, **onpload**, and **onpladm** utilities.

These topics are written for the following users:

- Database administrators
- Database server administrators

These topics assume that you have the following background:

- A working knowledge of your computer, your operating system, and the utilities that your operating system provides.
- Some experience working with relational databases or exposure to database concepts.
- Some experience with computer programming.
- Some experience with database server administration, operating-system administration, or network administration.

For information about software compatibility, see the IBM Informix release notes.

These topics are taken from *IBM Informix High-Performance Loader User's Guide*.

- High-Performance Loader overview
- Examples of loading and unloading jobs using the ipload utility
  This section shows how the components of the High-Performance Loader (HPL) fit together. The section includes a step-by-step tutorial with two examples (for a load and an unload job) that use the **ipload** graphical user interface (GUI).
- The ipload utility windows
  This section contains information about using the **ipload** utility.
- Define HPL projects
  This section explains how to create a project and how projects are related. The individual components that you store in projects are described in later sections.
- Configure the High-Performance Loader
  This section describes the process of configure the High-Performance Loader (HPL).
- Define device arrays
  This section describes how to define and use device arrays with the High-Performance Loader (HPL).
- Define formats
  This section describes the formats that the High-Performance Loader (HPL) provides and shows how to prepare and edit the format component.
- Define queries
  This section describe how to define queries including how to create, edit, and export and import queries.
- Define maps
  This section describes how to define maps with the High-Performance Loader (HPL). It also describes the options that are available for defining maps.
- Define filters
  This section describes how to create, edit, and delete filters.
- Unload data from a database
  This section describes the Unload Job window.
- Load data to a database table
  This section describes the load process.
- The Generate options of the ipload utility
  This section describes the Generate options for the **ipload** utility.
- The HPL browsing options
  This section describes the browsing options that are available for the High-Performance Loader (HPL).
- Manage the High-Performance Loader
- The onpload utility
  This section describes how to use the **onpload** utility.
- The onpladm utility
  This section describes how to use the **onpladm** utility.
- Appendixes
  This section contains additional reference information.

High-Performance Loader overview

- Overview of HPL features
  The High-Performance Loader (HPL) is a database server tool that you can use to load and unload large quantities of data efficiently to or from a database.
- The HPL data-load process
  The data-load process reads a source data file, converts the data to a different format, and inserts the converted data into a database table.
- The HPL data-unload process

- HPL loading modes
  The High-Performance Loader (HPL) offers two load modes, deluxe mode and express mode. The express mode is faster, and the deluxe mode is more flexible.
- HPL components
  The HPL consists of the **onpload** utility, the **ipload** utility, the **onpladm** command-line utility, and the onpload database.
- Environment variables needed for the HPL
  The High-Performance Loader (HPL) is part of the database server, so you must start the database server before you use the HPL. Before you start the database server and use HPL, you must set environment variables.
- Architecture of the onpload utility
  The **ipload** utility is the interface that allows you to prepare the parameters that the **onpload** utility uses. The **onpload** utility, which is a client application that attaches to the database server, actually loads and unloads the data.

Overview of HPL features

The High-Performance Loader (HPL) is a database server tool that you can use to load and unload large quantities of data efficiently to or from a database.

The HPL lets you exchange data with tapes, data files, and programs, and converts data from these sources into a format compatible with IBM® Informix® databases. The HPL also allows you to manipulate and filter the data as you perform load and unload operations.

The HPL includes the following components:

- The **ipload** utility, which is a graphical user interface (GUI). This UNIX application helps you prepare load and unload jobs for both UNIX and Windows and includes the following functionality:
  - The **ipload** utility provides a Generate option that lets you automatically generate the HPL components that are required for a load or unload job.
  - The database-load feature lets you update your databases with data from any of the supported file types, while allowing you to control the format and selection of records from the input files. Data can be loaded from or unloaded to files, tapes, or application pipes (for UNIX), or to any combination of these three device types.
  - The load and unload operations run in the background of your multitasking operating system. Once the operation begins, you can continue to use **ipload** to perform other functions.
  - The **ipload** utility provides context-sensitive online help. The online help also includes a glossary.
- The **onpladm** utility, which is a command-line version of the **ipload** utility.
- The **onpload** utility, which allows you to control HPL from a script.

- The onpload database, which maintains information about load and unload jobs that you have prepared.

You use the **ipload** utility to manage the onpload database on any database server on your network.

Any database server on your network can use the onpload database, which contains parameters and controls that the HPL uses. This accessibility allows centralized management of your load and unload controls. These parameters and controls include the HPL components such as formats, maps, and projects.

The HPL:

- Supports COBOL, ASCII, multibyte, delimited, or binary data.
- Can load and unload data of a different GLS locale than that of the database server.
- Provides synonym support for tables that are valid for the local database server. You can use synonyms for both the load and unload operations.
- Provides support for unloading data with a query that accesses a view in its SELECT statement.
- Supports loading of raw tables in express mode.

The HPL data-load process

The data-load process reads a source data file, converts the data to a different format, and inserts the converted data into a database table.

The source data can come from one or more of the following sources:

- Files
- Tapes
- Pipes (application-generated data) (UNIX)

The High-Performance Loader (HPL) supports load and unload data greater than 2 GB to files and tapes.

During conversion, the source data is often manipulated so that the converted data displays different characteristics. Examples of this manipulation include:

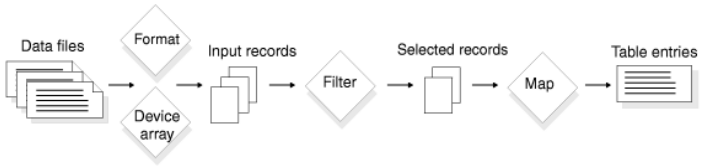
- Changing lowercase letters to uppercase letters
- Loading default values, loading certain table columns, or replacing nulls
- Masking the data to include only part of a value
- Converting from one data type to another, such as conversion of a numeric string to a float
- Converting from the code set of one locale to the code set of another locale

When you prepare to run a data load with the HPL, you describe the actions that the HPL must take by defining a set of metadata *components*. The components describe different aspects of the load process. The HPL uses information from:

- The device array to find the set of the source-data files
- The format to define the data types and layout of the source data
- The filter to select the records from the source data that should be written to the database table
- The map to modify and reorganize the data

The **ipload** utility helps you prepare the components. Load data to a database table, addresses the process of loading a file to a database.

The following figure shows the data load process. The figure summarizes the data-load process by showing how data moves from data files to table entries.
Figure 1. The data-load process



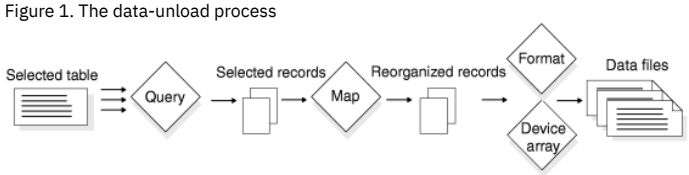
The HPL data-unload process

The data-unload process is essentially the same as the load process, but in reverse. The data-unload process extracts the source data from one or more database tables; converts the data to a new format; and writes the converted data to a file, tape, or on UNIX to a pipe (application). As in a load, you can manipulate the data from a database table so that the converted data displays different characteristics.

The following figure shows how the components of the High-Performance Loader (HPL) affect the data as it moves from a database to data files during the unload process. The HPL uses:

- The query to select records from the database
- The map to reorganize or modify the selected records
- The format to prepare the records for writing out to the data files
- The device array to find the location of the data files

Figure 1. The data-unload process



The HPL uses the same components for an unload job as for a load job, with one exception. For an unload job, **ipload** creates a Structured Query Language (SQL) query that extracts selected data from the table. As with a load, unload components are grouped together into an unload job. Unload jobs can be saved, retrieved, and rerun as many times as necessary. Unload jobs can be grouped together with load jobs in the same project.

Related reference:
Unload data from a database

HPL loading modes

The High-Performance Loader (HPL) offers two load modes, deluxe mode and express mode. The express mode is faster, and the deluxe mode is more flexible.

The HPL express mode

The HPL express-mode loads are faster than deluxe-mode loads, but less flexible. In express mode, you cannot update the table or read the new data entries until the load is complete. The express mode disables indexes, constraints, and triggers during the load. After the load, HPL rebuilds and re-enables indexes, evaluates and re-enables constraints, if possible, and re-enables triggers. (HPL does not evaluate triggers with respect to the loaded data.)

You must perform a level-0 backup after an express-mode load.

The HPL deluxe mode

The HPL deluxe-mode loads are not as fast as express-mode loads, but are more flexible. In deluxe mode, you can access and update the table that is being loaded. The deluxe mode updates indexes, performs constraint checking, and evaluates triggers as data is inserted into the table.

Related reference:
Manage the High-Performance Loader

HPL components

The HPL consists of the **onpload** utility, the **ipload** utility, the **onpladm** command-line utility, and the onpload database.

- The onpload utility
- The ipload utility
- The onpladm utility
  The **onpladm** utility is a command-line utility for both UNIX and Windows with the same functionality as **ipload**.
- The onpload database
- Relationships among the parts of the HPL

The onpload utility

The **onpload** utility has the following features:

- Converts, filters, and moves data between a database and a storage device
- Uses information from the onpload database to run the load and unload jobs and to convert the data
- Records information during a load about data records that do not meet the load criteria

The **onpload** utility can load or unload data from files that are larger than 2 GB and can generate .log, .rej and .flt files that are larger than 2 GB.

The **onpload** database must be accessible from the machine on which the **onpload** utility is run. It does not need to be on the same machine.

The database that the **onpload** loads or unloads must be in a database server instance on the machine that is running the **onpload** (or **ipload** or **onpladm**) utility.

You can start **onpload** by using **ipload** or from the command line.

When you start **onpload** from **ipload**, the **onpload** and **ipload** utilities communicate by using a socket connection. The **onpload** utility runs independently from **ipload** (see the information to the right of the vertical line in Figure 1).

Related concepts:
Architecture of the onpload utility
Related reference:
The onpload utility

The ipload utility

The **ipload** utility is a UNIX-based graphical user interface that has the following features:

- Creates and manages the onpload database
- Creates and stores information for onpload
- Lets you create, edit, and group the components of the load and unload jobs
- Stores information about the load components in the database

You can use **ipload** to manage onpload databases on both UNIX and Windows. The **ipload** utility is not available on Mac OS X.

Related concepts:
Start the ipload utility
Related reference:
The ipload utility
Configure the ipload utility
Run load and unload jobs on a Windows computer

The onpladm utility

The **onpladm** utility is a command-line utility for both UNIX and Windows with the same functionality as **ipload**.

Related reference:
The onpladm utility

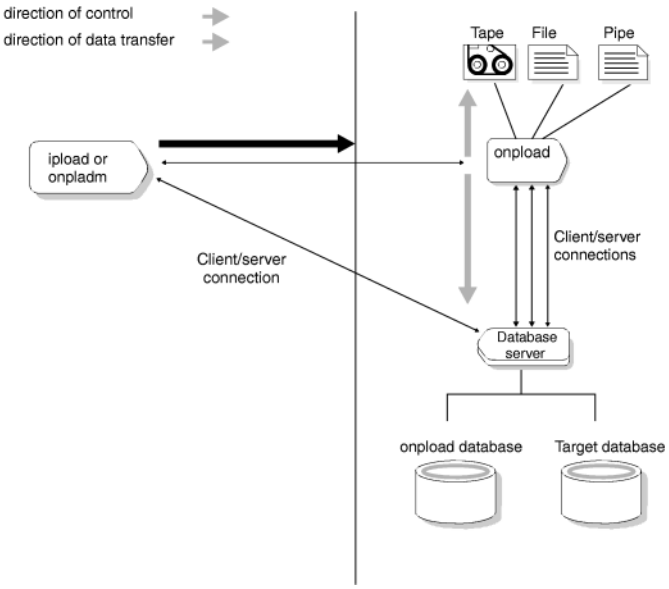
The onpload database

The onpload database has the following features:

- Contains information that the **onpload** utility requires to perform data loads and unloads
- Must be accessible from the machine where the **onpload** utility is run. It does not need to be on the same machine.
  However; the database that the utility loads or unloads must be in a database server instance on the machine where the **onpload** utility (and hence the **ipload** or **onpladm** utility) is being run.

Relationships among the parts of the HPL

The following figure shows the relationships among the parts of the High-Performance Loader (HPL). The **ipload** utility or **onpladm** command-line utility connects to the database server to populate the onpload database. The **ipload** utility or the **onpladm** utility controls the **onpload** utility, which uses multithreaded architecture to make multiple connections to the database server and multiple I/O connections to tapes, files, or pipes.
Figure 1. Relationships among the parts of the HPL



The information to the right of the vertical line in Figure 1 shows **onpload** loading or unloading data with no interaction from **ipload**.

Environment variables needed for the HPL

The High-Performance Loader (HPL) is part of the database server, so you must start the database server before you use the HPL. Before you start the database server and use HPL, you must set environment variables.

The following environment variable must be set:

- INFORMIXDIR
- ONCONFIG
- INFORMIXSERVER
- LD_LIBRARY_PATH

Some computers use the LD_LIBRARY_PATH environment variable for shared libraries. The name of this environment variable is platform-dependent. See your operating system documentation for the name of the environment variable that specifies the search path for shared libraries. Then see the machine notes for information about LD_LIBRARY_PATH.

You can use the IFX_ONPLOAD_AUTO_UPGRADE environment variable with the **ipload** or **onpladm** utilities to automatically upgrade the onpload database the first time you run an HPL utility by using the **ipload** or **onpladm** command after you migrate to a new database server version. You cannot use the IFX_ONPLOAD_AUTO_UPGRADE environment variable with the **onpload** utility.

In addition to the environment variables listed above, the following environment variables pertain to the HPL:

- DBONPLOAD
- PLCONFIG
- PLOAD_SHMBASE
- PLOAD_LO_PATH
- PLOAD_SHMAT

Tip: To maximize available memory and scan resources, HPL automatically sets the PDQPRIORITY environment variable to `100`, if it is not already set. If the PDQPRIORITY environment variable is set, HPL uses that value. If the PDQPRIORITY environment variable is set to `0`, then HPL cannot unload multiple devices.

- Preparing multiple onpload databases
  Each database server can have only one active onpload database. In most cases, you can use the default onpload database, which is named onpload. If you choose to prepare multiple databases to hold different types of control information, you must set the DBONPLOAD environment variable before you can run a load or unload.
- The PLCONFIG environment variable
- The PLOAD_SHMBASE environment variable
- The PLOAD_LO_PATH environment variable
  The PLOAD_LO_PATH environment variable allows you to specify the location of smart large object (CLOB or BLOB) output files. If this environment variable is not set, the database server puts the output files in /tmp.
- The PLOAD_SHMAT environment variable
  If the pload converter thread cannot attach to the passed address, you receive a message that asks you to set the PLOAD_SHMAT environment variable.

Related information:
INFORMIXDIR environment variable
INFORMIXSERVER environment variable
ONCONFIG environment variable
PDQPRIORITY environment variable

Preparing multiple onpload databases

Each database server can have only one active onpload database. In most cases, you can use the default onpload database, which is named onpload. If you choose to prepare multiple databases to hold different types of control information, you must set the DBONPLOAD environment variable before you can run a load or unload.

To prepare multiple onpload databases with **ipload**:

1. Set the DBONPLOAD environment variable to the name of the alternative onpload database.
2. Restart **ipload**.
3. Use **ipload** to prepare the alternative database.

During load and unload jobs, the **ipload**, **onpload**, and **onpladm** utilities use the value of the DBONPLOAD environment variable that is set in the client environment, regardless of whether the DBONPLOAD environment variable is set on the server. The **ipload**, **onpload**, and **onpladm** utilities use the value of the DBONPLOAD environment variable that is set on the server only if the DBONPLOAD environment variable is not set in the client environment.

Related concepts:
Create the onpload database
Related information:
DBONPLOAD environment variable

The PLCONFIG environment variable

The default configuration file for the **onpload** utility is plconfig.std. The configuration file is always in the $INFORMIXDIR/etc directory. To use an alternative configuration file, you must set the PLCONFIG environment variable to the name of the alternative **onpload** configuration file. If you use plconfig.std, you do not need to set PLCONFIG.

Related reference:
High-Performance Loader configuration file
Related information:
PLCONFIG environment variable

The PLOAD_SHMBASE environment variable

The PLOAD_SHMBASE environment variable allows you to specify shared-memory address attachments specifically for **onpload** processes. You can set the PLOAD_SHMBASE environment variable to avoid shared-memory collisions between **onpload** and the database server or allow the HPL to specify the attachments.
Tip: To use the PLOAD_SHMBASE environment variable, you must start **onpload** from the command line, not from within **ipload**.

- Avoid shared-memory collision
- Set the PLOAD_SHMBASE environment variable
  To override the initial shared-memory allocation in a shared-memory collision between **onpload** and the database server, set the PLOAD_SHMBASE environment variable to a value much higher or much lower than the value for the shared memory that the database server uses.

Related information:
PLOAD_SHMBASE environment variable

Avoid shared-memory collision

Both the database server and onpload allocate shared memory. When onpload starts up, the database server allocates shared memory for buffers for **onpload** processes. The **onpload** utility also allocates shared memory for its internal use. Because of the dynamic nature of shared-memory allocations, shared-memory collisions can occur between onpload and the database server. If this collision occurs, the **onpload** job can also fail and error messages are sent to the **onpload** log file or the database server log file.

To verify if a collision has occurred, use the **onstat -g seg** option. Check for overlap between the shared-memory segments that the database server is using and the SHMBASE reported in the **onpload** log file.

Related information:
onstat -g seg command: Print shared memory segment statistics

Set the PLOAD_SHMBASE environment variable

To override the initial shared-memory allocation in a shared-memory collision between **onpload** and the database server, set the PLOAD_SHMBASE environment variable to a value much higher or much lower than the value for the shared memory that the database server uses.

The PLOAD_LO_PATH environment variable

The PLOAD_LO_PATH environment variable allows you to specify the location of smart large object (CLOB or BLOB) output files. If this environment variable is not set, the database server puts the output files in /tmp.

Related information:
PLOAD_LO_PATH environment variable

The PLOAD_SHMAT environment variable

If the pload converter thread cannot attach to the passed address, you receive a message that asks you to set the PLOAD_SHMAT environment variable.

When you set the PLOAD_SHMAT environment variable, the pload converter calculates the address by using a global attached segment list that is maintained across pload virtual processors. The pload converter attaches at the next available address after the highest address on the list, ensuring that the converter always attaches to an unused shared memory segment.

Architecture of the onpload utility

The **ipload** utility is the interface that allows you to prepare the parameters that the **onpload** utility uses. The **onpload** utility, which is a client application that attaches to the database server, actually loads and unloads the data.

The **onpload** utility can take advantage of parallel processing to perform both I/O and data conversion as efficiently as possible because it uses the same multithreading architecture that the database server uses.

The following sections describe how **onpload** uses multithreading for deluxe loads, express loads, and unloads.

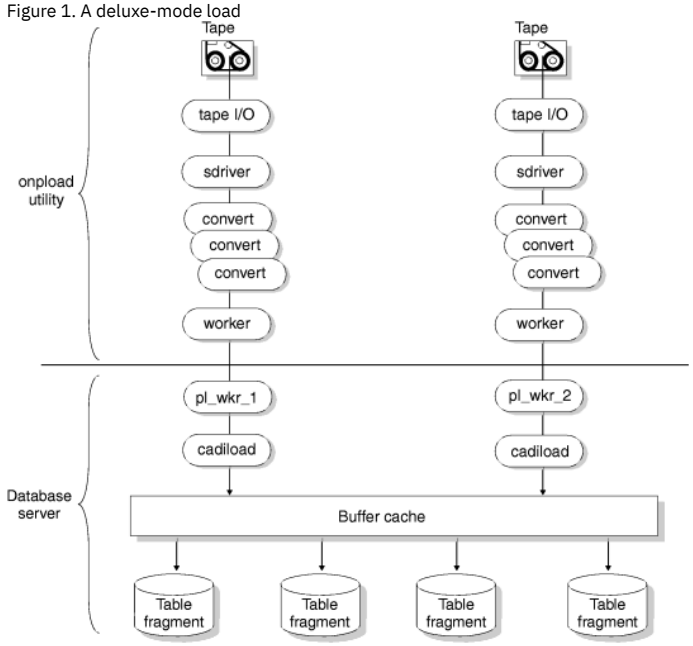
- The onpload utility deluxe-mode process
  The **onpload** utility uses specific threads during the deluxe-mode process.
- The onpload utility express-mode load process
  The **onpload** utility behaves the same way during express-mode deluxe-mode loads. However, the database server behaves differently during an express load.
- The onpload utility unload process

Related concepts:
The onpload utility
Related information:
Save memory and resources

The onpload utility deluxe-mode process

The **onpload** utility uses specific threads during the deluxe-mode process.

The following figure shows the threads that **onpload** uses in a deluxe-mode load process. In deluxe mode, data is subject to the same constraints as if it were loaded by using SQL INSERT statements.
Figure 1. A deluxe-mode load



- Threads that the onpload utility uses
- Threads that the database server uses

Related concepts:
The HPL deluxe mode

Threads that the onpload utility uses

The **onpload** utility starts the following threads:

Table 1. Threads that the onpload utility starts

Thread	Description
tape I/O threads	The **onpload** utility starts one **tape I/O** thread for each tape device. It reads data from the tape device asynchronously. The **onpload** utility starts a similar thread for piped output. (UNIX only) If the disk file inputs, **onpload** uses the multithreading AIO subsystem instead of a dedicated **I/O** thread.
sdriver threads	The **worker** threads control **I/O** from input files. They handle device abstraction for the different device types handled. The **sdriver** threads also are responsible for passing out records from the input and passing records to the converters.
convert threads	The **onpload** utility starts one or more **convert** threads for each device. These threads perform conversions on the input data such as uppercase to lowercase conversion or code-set conversion.
worker threads	The **onpload** utility starts one **worker** thread for each input device. These threads communicate with the database server. The main responsibility of the **worker** thread is to pass data to the database server.

To see the status of the **onpload** threads, you must use the **-j** option of the **onstat** utility.

Related reference:
The onstat -j option

Threads that the database server uses

The database server uses the following threads to insert the data into the database:

Table 1. Threads that insert data into the database

Thread	Description
pl_wkr threads	Each **worker** thread of the **onpload** utility is paired with a **pl_wkr** thread in the database server. These threads receive the data from **onpload**. In a utility that shows the database server status, the **pl_wkr** threads are named **pl_wkr_1**, **pl_wkr_2**, **pl_wkr_3**, and so on.
cadiload threads	The **cadiload** threads are the **insert** threads. The **insert** threads perform a normal insert into the database, like during an INSERT statement. The SQL optimizer governs the method that is used for inserting the data.

The onpload utility express-mode load process

The **onpload** utility behaves the same way during express-mode deluxe-mode loads. However, the database server behaves differently during an express load.

During an express-mode load, the **pl_wkr** threads pass the data to **stream** threads (also called **fragmenter** threads) that decide where the data is to be stored. The **fragmenter** threads pass the data to an exchange that distributes the data to **setrw** threads. The **setrw** threads write table rows to disk a page at a time, bypassing the buffer cache.

The number of input devices can be different from the number of table fragments. The exchange operator handles multiplexing of data. The data is processed in parallel with respect to the data read from the device array and also with respect to the data written out to table fragments on separate disks. Pipeline parallelism is also present in the data flow from input devices to table fragments on disk. Parallelism is the main mechanism for achieving high performance.

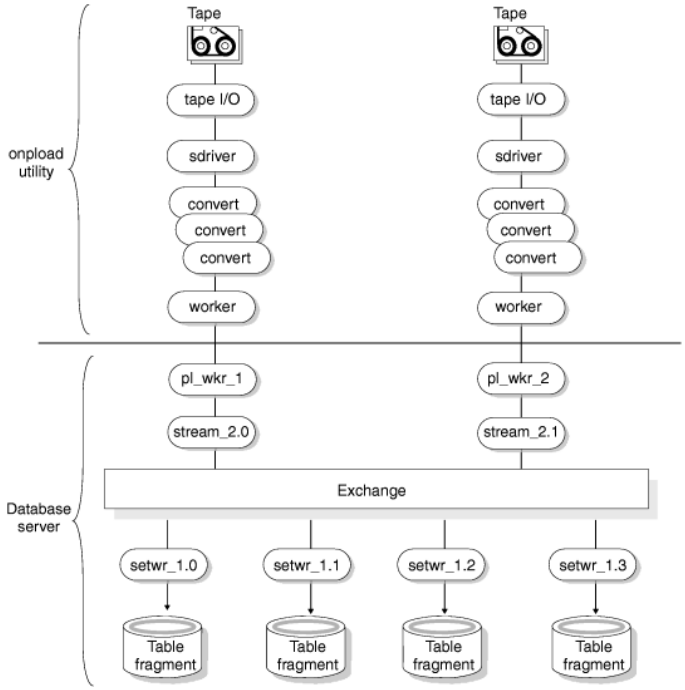
During express-mode load, the database server writes the data to new extents on disk, but those extents are not yet part of the table. At the end of an express-mode load, the database server adds the new extents to the table.

Important: After the express-mode load, you must perform a level-0 backup before you can write to the target database. If you try to write to the table before you perform a level-0 backup, the database server issues ISAM error -197, as follows:

```
Partition recently appended to; can't open for write or logging.
```

If your database is ANSI-compliant, all access (both read and write) is denied until you perform a level-0 backup. Because data is not logged in express mode, the level-0 backup is necessary to allow for recovery in case of media failure.

The following figure shows a single express-mode load process. In express mode, the data is inserted directly into an extent without any evaluation of objects such as constraints, indexes, or triggers.
Figure 1. An express-mode load

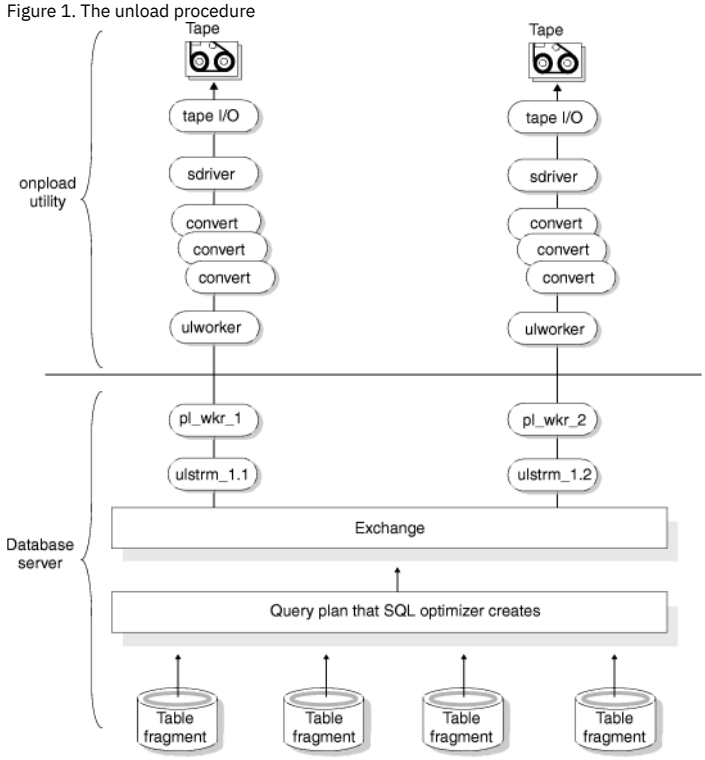


Related concepts:
The HPL express mode

The onpload utility unload process

The following figure shows the **onpload** unload process. In the unload process, the behavior of **onpload** parallels the behavior described in Threads that the onpload utility uses and Threads that the database server uses, except that the threads are unloading the data instead of loading it.

Figure 1. The unload procedure



The **ulstrm** (unload-stream) thread packages data for output to the **onpload** client from the query plan. The SQL optimizer creates the query plan. The query plan behaves like a query plan running from any other client, such as DB-Acess. The exchange operator distributes the resulting data to the **ulworker** threads in a round-robin fashion, and **onpload** unloads the data onto tapes or files.

Parallelism with respect to the output device, the source table fragments, and the flow of the data is evident in the preceding figure.

Examples of loading and unloading jobs using the ipload utility

This section shows how the components of the High-Performance Loader (HPL) fit together. The section includes a step-by-step tutorial with two examples (for a load and an unload job) that use the **ipload** graphical user interface (GUI).

The illustrations in the first example use a database with only one table. The table contains three columns. The data to be loaded into the database is in a file that has only four records. In a real production environment, you would probably use the INSERT statement, the **dbimport** utility, or the LOAD statement for such a simple operation. However, by using a simple example, the illustrations can show what happens at each step.

The **onpladm** command-line interface is equivalent to the **ipload** utility.

- Prepare to use the ipload utility
  The **ipload** utility is a part of UNIX database servers. Before you can use **ipload**, you must have installed the database server. If the database that you want to load or unload is on the computer where you plan to run **ipload**, you must also start the database server.
- Create a file of data
- Create a database
- The ipload utility
  The High-Performance Loader (HPL) uses information from the onpload database to control loading and unloading of data. Theoretically, you could create the onpload database and use DB-Acess or some other database tool to populate it. However, it is recommended that you always use **ipload** to manage the onpload database.
- Load Job windows
  A load job is a collection of the specific pieces of information that you require to move data from a data file into a database. The Load Job window shows a flowchart that includes all of the components of a load job.
- Device-Array windows
  A device array is a collection of files, tape devices, and pipes that **onpload** uses for input and output. Pipes are only supported on UNIX. You can create a device array and specify the location of the input data from the Device Array Selection and Device-Array Definition windows.
- Format windows
  The format specifies the organization of the input data.
- Filter, Discard Records, and Logfile text boxes
  The Load Job window now has entries for a device and format. The next incomplete items in the Load Job window are the Filter text box, the Discard Records text box, and the Logfile text box.
- Map Views window
  From the Map Views window, you can create a map that specifies which data field from the input file (/work/mydata) is entered into which columns in the database table.
- Completing the Load Record Maps window
  The Load Record Maps window specifies the device array that holds the input data, the format that describes the input data, and the database and table where the input data will be stored.
- Map-Definition window
- Load Options window
- Running the ipload job
  You are now ready to perform the load.
- Active Job window
- The ipload utility Generate options
  The **ipload** utility has Generate options that you can use to automatically create a format, map, query, and device. After the components are generated, you can modify the components to meet your needs.

The onpladm utility

Prepare to use the ipload utility

The **ipload** utility is a part of UNIX database servers. Before you can use **ipload**, you must have installed the database server. If the database that you want to load or unload is on the computer where you plan to run **ipload**, you must also start the database server.

You can also use **ipload** to manage load and unload operations for a database server on a different computer. For example, you can use **ipload** on a UNIX computer to manage the onpload database on a Windows computer.

Related reference:
Run load and unload jobs on a Windows computer

Create a file of data

The illustrations in this section assume that the data to be loaded is in a file named /work/mydata. Create a file that contains the following data:

```
1|a|50
2|b|25
3|c|10
4|d|5
```

Create a database

The High-Performance Loader (HPL) loads data into an existing table in an existing database. The examples in this section load the information from the file /work/mydata into a three-column table named **tab1** in a database named **testdb**. You can use DB-Acess to prepare the database and table, as follows:

```
CREATE DATABASE testdb;
CREATE TABLE tab1
(
```

```
col1 INTEGER,
col2 CHAR(1),
col3 INTEGER
);
GRANT ALL ON tab1 TO PUBLIC;
GRANT CONNECT TO PUBLIC;
```

After you finish preparing the database for the examples, exit from DB-Acess.

The ipload utility

The High-Performance Loader (HPL) uses information from the onpload database to control loading and unloading of data. Theoretically, you could create the onpload database and use DB-Acess or some other database tool to populate it. However, it is recommended that you always use **ipload** to manage the onpload database.

- Start the ipload utility
  To start **ipload**, type the following at the system prompt `ipload`.
- Choose a project
  You use the High-Performance Loader (HPL) by preparing load jobs that import data or unload jobs that export data. You can assign the load and unload jobs to various projects to organize the jobs into functional groups.
- Check the ipload utility default values
  The default values that **ipload** selects when it is first started specify machine type, character code set for character-type data, and other operating characteristics. In most cases, the only default that you might need to change is the machine type.

Related concepts:
The ipload utility

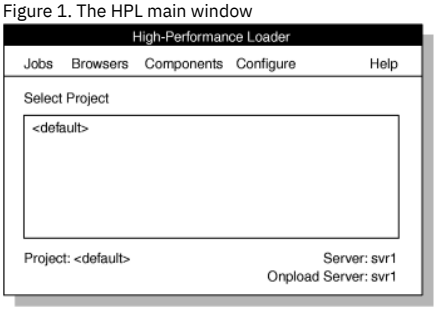
Start the ipload utility

To start **ipload**, type the following at the system prompt `ipload`.

A decorative splash screen appears and stays on the display while **ipload** finishes loading. If you do not want to see the splash screen, use the **-n** flag, `ipload -n`.

The first time you start **ipload**, it automatically creates the onpload database. The **ipload** utility also puts certain default values into the database.

When **ipload** starts, the High-Performance Loader (HPL) main window appears, as the following figure shows.
Figure 1. The HPL main window



Tip: To exit from **ipload**, choose **Exit** from the **Jobs** menu.
The **onpladm** command-line utility provides the same functionality as the **ipload** graphical user interface.

Related reference:
The onpladm utility
The onpload database

Choose a project

You use the High-Performance Loader (HPL) by preparing load jobs that import data or unload jobs that export data. You can assign the load and unload jobs to various projects to organize the jobs into functional groups.

The **ipload** utility automatically creates a project named **<default>**. If you choose not to organize your work into projects, you can put all of the load and unload jobs in the default project.

For this example, you can use the default project. Click <default> on the HPL main window to choose the default project.

Related concepts:
Define HPL projects

Check the ipload utility default values

The default values that **ipload** selects when it is first started specify machine type, character code set for character-type data, and other operating characteristics. In most cases, the only default that you might need to change is the machine type.

- Look at the Defaults window
  Choose Configure > Defaults to see the current default values. After you check the defaults, you can click Cancel to exit from the Defaults window.
- Look at the Machines window
  Choose Configure > Machines to see the current default values. Make sure that the machine type displayed in the Machines window matches the current machine type. Click the Machine > Type down arrow to select a machine type. Click Cancel to exit from the Machines window.

Related reference:
Configure the High-Performance Loader

Look at the Defaults window

Choose Configure > Defaults to see the current default values. After you check the defaults, you can click Cancel to exit from the Defaults window.

Related concepts:
Modify the onpload default values

Look at the Machines window

Choose Configure > Machines to see the current default values. Make sure that the machine type displayed in the Machines window matches the current machine type. Click the Machine > Type down arrow to select a machine type. Click Cancel to exit from the Machines window.

Related concepts:
Modify the machine description

Load Job windows

A load job is a collection of the specific pieces of information that you require to move data from a data file into a database. The Load Job window shows a flowchart that includes all of the components of a load job.

The Load Job window is illustrated in Figure 2. After you become familiar with **ipload**, you can create or modify the individual components of a load or unload job with direct menu choices from the HPL main window.

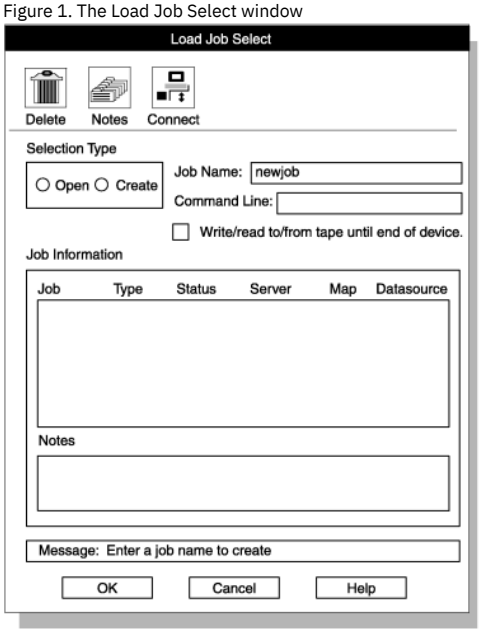
- Load Job Select window
  The data-load example takes records from /work/mydata and loads them into **tab1** of the **testdb** database. To perform the load, you need to create a load job.
- Load Job window

Load Job Select window

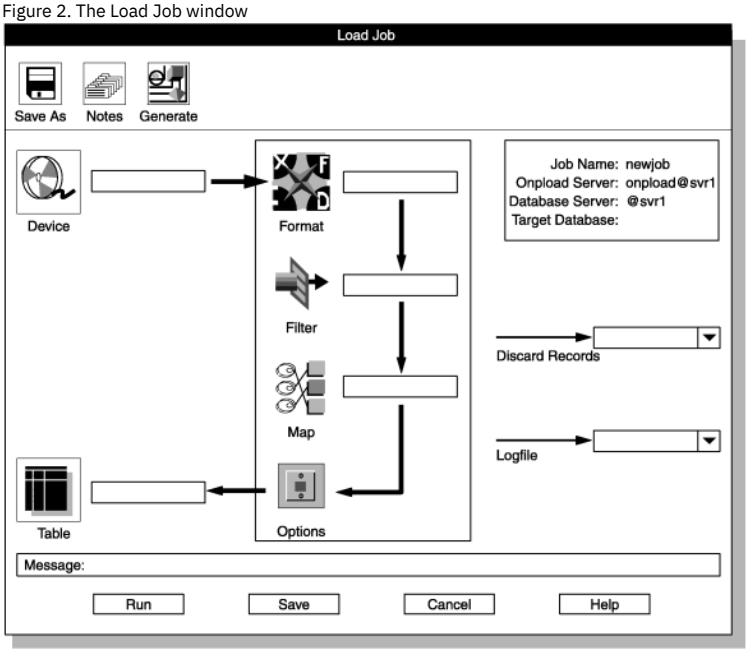
The data-load example takes records from /work/mydata and loads them into **tab1** of the **testdb** database. To perform the load, you need to create a load job.

To create a load job:

1. Choose Jobs > Load from the HPL window.
   The Load Job Select window appears, as the following figure shows.
   Figure 1. The Load Job Select window



2. Click Create in the Selection Type group.
3. Choose a name for the load job and type it in the Job Name text box. This example uses **newjob**.
4. Click OK.
   The Load Job window appears, as the following figure shows.
   Figure 2. The Load Job window



Load Job window

The thick arrows on the Load Job window indicate the steps that you take as you build a load job. The icons indicate the task at each step. The thin arrows indicate file names for error recording. To create a load job, you need to complete the following tasks:

Task	**Click**
Specify the source of the data	Device
Describe the data	Format
Tell **ipload** which data you want to discard (optional)	Filter
Specify association between input fields and load-table columns	Map
Specify options for the load job	Options
Specify the database table to load	Table
Record rejected data records (optional)	Discard Records
Record information about the job (optional)	Logfile

Device-Array windows

A device array is a collection of files, tape devices, and pipes that **onpload** uses for input and output. Pipes are only supported on UNIX. You can create a device array and specify the location of the input data from the Device Array Selection and Device-Array Definition windows.

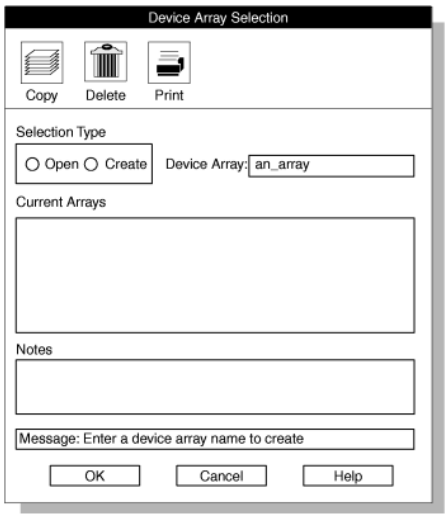
In this example, the input data is the /work/mydata file that you created in Create a file of data.

- Device Array Selection window
- Device-Array Definition window

Device Array Selection window

To create a device array:

1. Click Device in the Load Job window.
   The Device Array Selection window appears, as the following figure shows.
   Figure 1. The Device Array Selection window

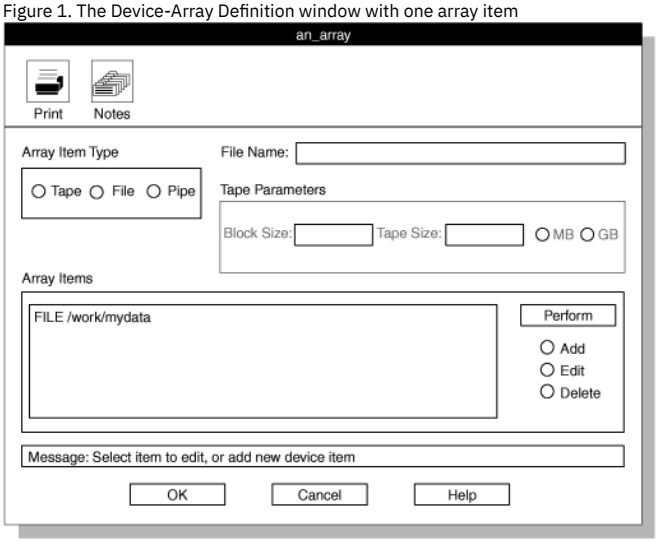


2. Click Create in the Selection Type group.
3. Select a name for the device array and type it in the Device Array text box. This example uses **an_array**.
4. Click OK.
   The Device-Array Definition window appears, as Figure 1 shows.

Device-Array Definition window

The title bar of the Device-Array Definition window shows the array name that you typed in the Device Array text box.

Figure 1. The Device-Array Definition window with one array item



To add a device to the array:

1. Click Add in the Perform group (lower right).
2. Click File in the Array Item Type group (upper left).
3. Type the full path name of a device in the File Name text box. In this example, the device is /work/mydata.
4. Click Perform to add the /work/mydata file to the device array.
   The **ipload** utility lists each item of the device array in the Array Items list box. Figure 1 shows the window after you add /work/mydata to the array.
5. Click OK.
   The display returns to the Load Job window. The Device list box now displays the device array name that you chose.

Format windows

The format specifies the organization of the input data.

In this example, the input data is in the file /work/mydata, which you created in Create a file of data. Each record in the file has three fields.

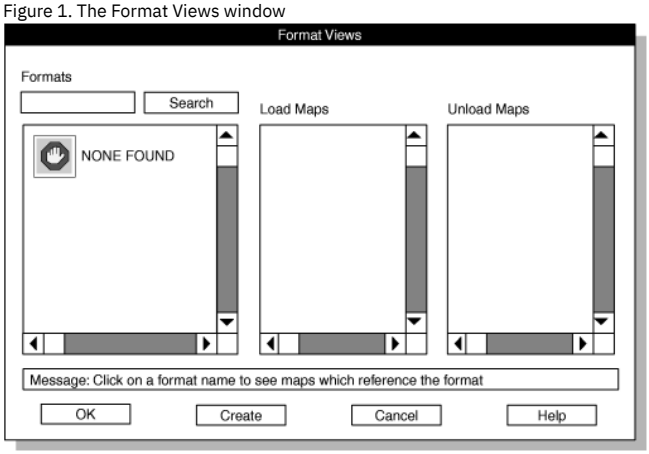
- Format Views window
  The Format Views window displays existing formats, so that you can choose the format to use in the load job.
- Record Formats window
- Format-Definition window
  In the Format-Definition window, you must make an entry for each field of the data records in the input file. The input file for this example (/work/mydata) has three fields of data in each record, so you must enter format information for three pieces of data.

Format Views window

The Format Views window displays existing formats, so that you can choose the format to use in the load job.

To open the Format Views window:

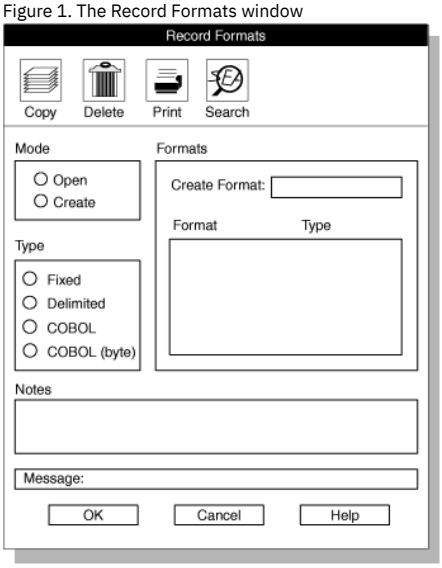
1. Click the Format in the Load Job window.
   The Format Views window appears, as the following figure shows. When you first start **ipload**, no formats are defined, as the NONE FOUND icon illustrates.
   Figure 1. The Format Views window



2. Click Create to open the Record Formats window.

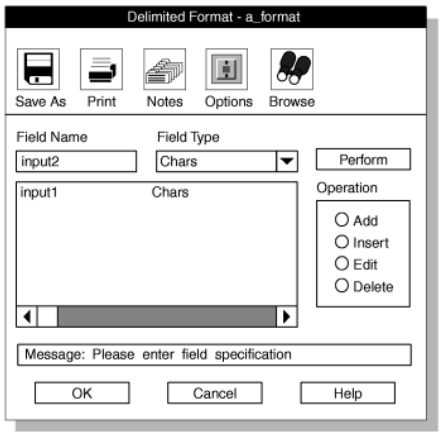
Record Formats window

The following figure shows the Record Formats window. You can create a format or open an existing format from the Record Formats window.
Figure 1. The Record Formats window



To create a format:

1. Click Create in the Mode group.
2. Click Delimited in the Type group.
   The input data file, /work/mydata, is in delimited format. Other formats are described in Define formats.
3. Choose a name for the format and type it in the Create Format text box. This example uses the name **a_format**.
4. Click OK.
   The Format-Definition window appears. The following figure shows a partially completed Format-Definition window. The title bar of the Format-Definition window shows the name that you chose for the new format.
   Figure 2. The Format-Definition window



Format-Definition window

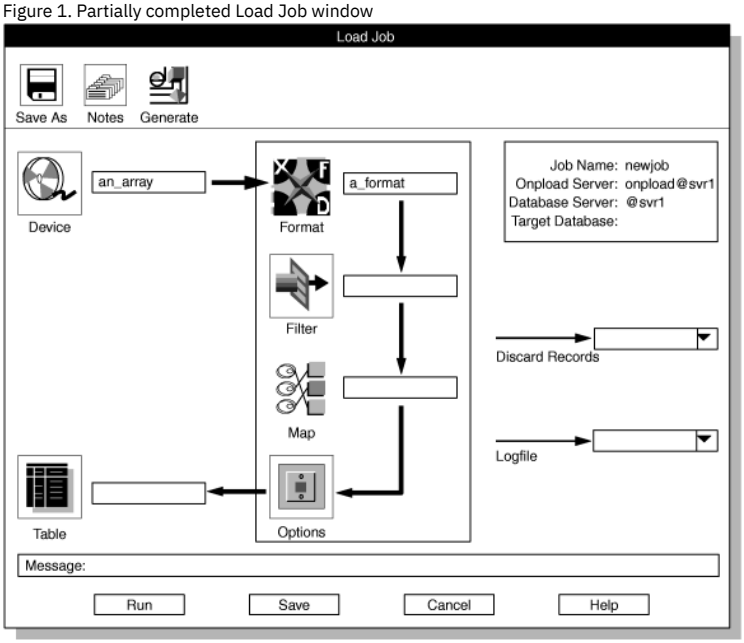
In the Format-Definition window, you must make an entry for each field of the data records in the input file. The input file for this example (/work/mydata) has three fields of data in each record, so you must enter format information for three pieces of data.

To enter a format definition:

1. Click Add in the Operation group.
2. In the Field Name text box, type a descriptive name for the first field of the data record.
   You can choose any descriptive name. This example uses **input1**, **input2**, and **input3** for the three fields of /work/mydata.
3. In the Field Type text box, type the data type or click the down arrow for a list of selections.
   Because the data in /work/mydata is simple ASCII data, the type is **Chars**. Other data types are discussed in Define formats.
4. Click Perform.
   Figure 2 shows the partially completed Format-Definition window. The entry for the first item is complete. The Field Name and Field Type for the second item are present and ready for you to click Perform.
5. Repeat steps 2 through 4 for each of the three input fields.
6. Click OK after you complete all of the input fields.
   The display returns to the Format-Views window, which displays the new format in the Formats list box.
7. Click Cancel to return to the Load Job window.

The Load Job window now displays the name of the device and the name of the format, as the following figure shows.

Figure 1. Partially completed Load Job window



Filter, Discard Records, and Logfile text boxes

The Load Job window now has entries for a device and format. The next incomplete items in the Load Job window are the Filter text box, the Discard Records text box, and the Logfile text box.

Filter text box

Use a filter to choose the records from the data file that should be inserted into the table. In this example, all of the records from the /work/mydata data file are inserted into the database table. Therefore, you do not need to create a filter. For this example, you can leave the Filter text box blank.

Define filters, describes how to create and use a filter.

Discard Records text box

The Discard Records text box specifies a file that keeps information about records that were rejected because of incorrect format or invalid data. For this example, you can leave the Discard Records text box blank.

Reviewing records that the conversion rejected describes how to view rejected records.

Logfile text box

The Logfile text box specifies a file where a record of the load or unload job is kept. For this example, you can leave the Logfile text box blank.

View the status of a load job or unload job describes how to view the log file.

Map Views window

From the Map Views window, you can create a map that specifies which data field from the input file (/work/mydata) is entered into which columns in the database table.

- Creating a map by using Map Views window
  Use the Map Views window to create a map or edit an existing map. You need to create a map that shows how the input data that the record format **a_format** describes is to be loaded into the table **tab1**.

Creating a map by using Map Views window

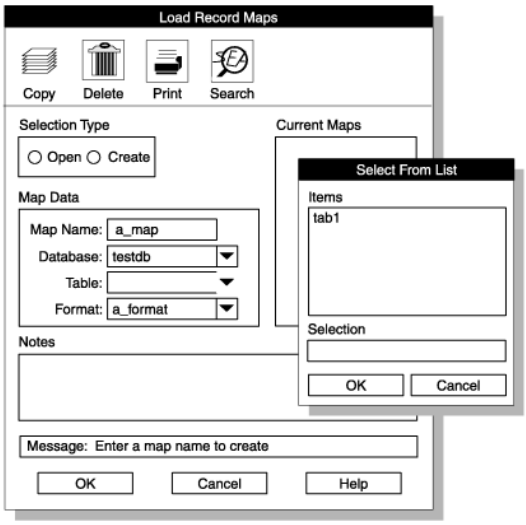
Use the Map Views window to create a map or edit an existing map. You need to create a map that shows how the input data that the record format **a_format** describes is to be loaded into the table **tab1**.

To create a map:

1. Click the Map button in the Load Job window.
   The Map Views window appears, as the following figure shows.
   Figure 1. The Map Views window

   The NONE FOUND icon in the Map column is appropriate. The Map Views window does not contain any information because you have not yet specified any relationships.

2. Click Create.
   The Load Record Maps window appears, as the following figure shows.
   Figure 2. A partially completed Load Record Maps window with an open selection list



Completing the Load Record Maps window

The Load Record Maps window specifies the device array that holds the input data, the format that describes the input data, and the database and table where the input data will be stored.

To complete the Load Record Maps window:

1. Click Create in the Selection Type group.
2. Select a name for the map and type it in the Map Name text box. This example uses **a_map**.
3. Type the name of your database (`testdb`) in the Database text box. Or, click the down arrow to select a database from the selection list.
4. Click the down arrow beside the Table text box to see a list of tables in the selected database.
   Figure 2 shows the Load Record Maps window and the selection list.
5. Select a table from the list and click OK.
   Because you already filled in the Format text box on the Load Jobs window, the Format text box is already complete.
6. Click OK to open the Map-Definition window.

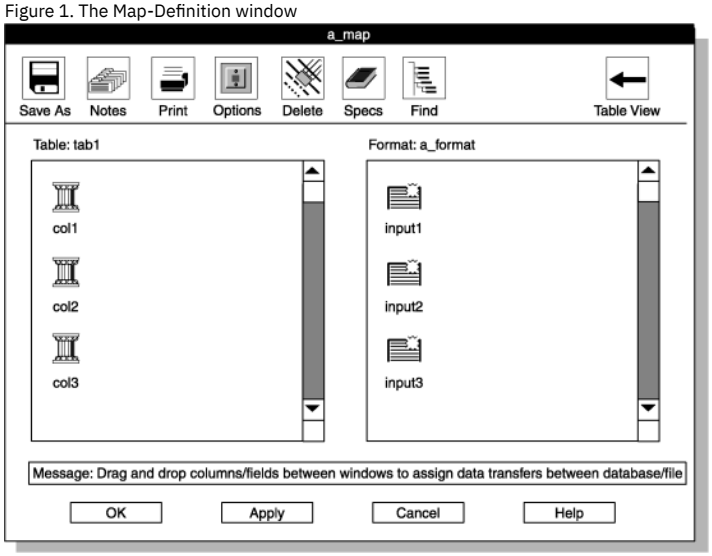
Map-Definition window

You can associate an input item with a table column in the Map-Definition window. This example stores the data from /work/mydata as follows, by using the field names assigned in step 1.

Data from input field	Goes into table column
input1	col3
input2	col2
input3	col1

The following figure shows the Map-Definition window. The title bar of this window shows the map name that you chose.

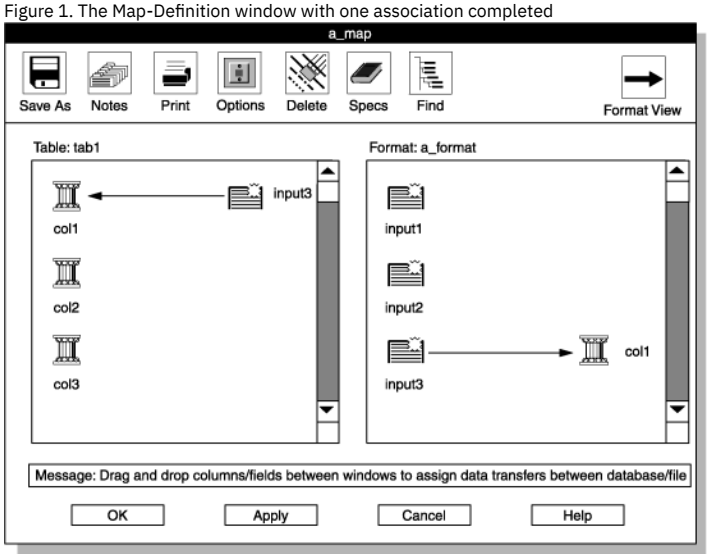
Figure 1. The Map-Definition window



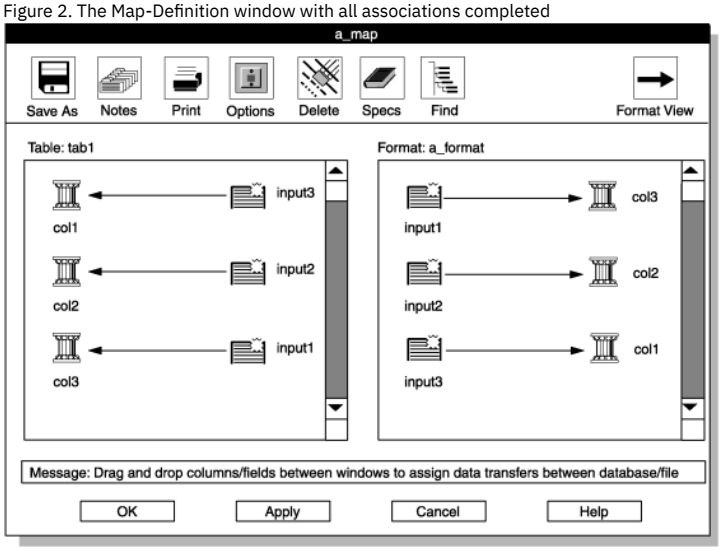
Associating each input item with a column of the database table

To associate each input item with a column of the database table:

1. Click the col1 icon and hold the mouse button down. A box appears around the icon and its name.
2. Drag the boxed icon to the input3 icon in the right pane.
3. Release the mouse button.
   The associated items appear in the second column of each pane. The following figure shows the Map-Definition window with this step completed.
   Figure 1. The Map-Definition window with one association completed

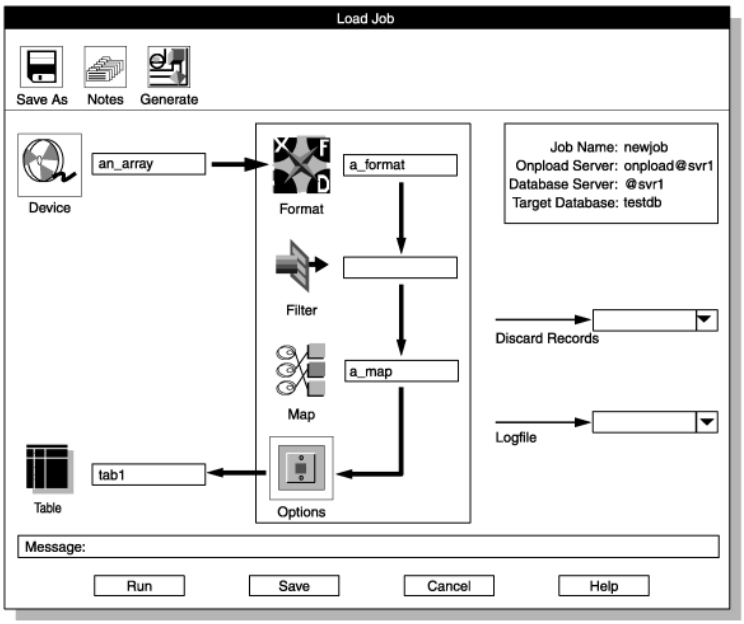


4. Connect **col2** to **input2**.
5. Connect **col3** to **input1**.
   The following figure shows the window with all three connections completed.
   Figure 2. The Map-Definition window with all associations completed



6. Click OK to return to the Map Views window.
7. Click Cancel to return to the Load Job window.

The Load Job window now has entries in all of the required areas, as the following figure shows. The **ipload** utility was able to enter the table name and the target database name (upper right area) because you specified the database and table as you built the map.
Figure 3. The Load Job window with all required component boxes completed

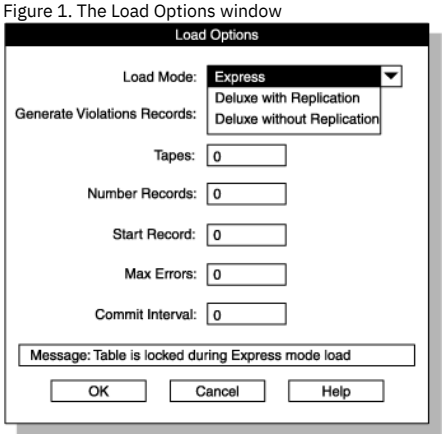


You have finished all of the required parts of the Load Job window, but you might want to modify the options, as discussed in the next section.

Load Options window

The High-Performance Loader (HPL) has three modes of operation: express, deluxe with replication, and deluxe without replication. The express mode is optimized for speed and the deluxe mode provides the full functionality of SQL inserts as data is loaded. For a detailed comparison of these modes, see Manage the High-Performance Loader. This example uses the express mode.

To set the load-job options:

1. Click Options in the Load Job window.
   The Load Options window appears, as the following figure shows.
   Figure 1. The Load Options window
   


2. Select Express from the Load Mode list box.
3. Select Yes from the Generate Violations Records list box.
4. Make sure all of the other entries are `0`.
5. Click OK to return to the Load Job window.

Running the ipload job

You are now ready to perform the load.

To finish this example:

1. Click Save to save the load job.
   After you save the load job, the message line displays the following message:

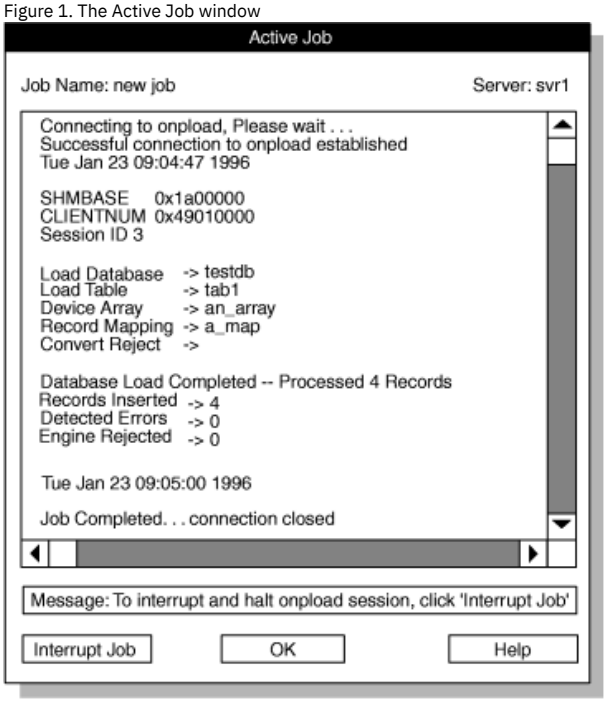
   ```
   Saved job successfully
   ```

   You can now run the job, or you can return at a later time and run the job.
2. Click Run to run the load job.
   The Active Job window appears, as Figure 1 shows.

Tip: The **ipload** utility generates an **onpload** command and then runs the command to run your job. To see the command that **ipload** generates, look at the Command Line text box on the Load Job Select window. For more information, see The command-line information.

Active Job window

The Active Job window reports the progress of your job. The following figure shows the Active Job window after the load is complete.
Figure 1. The Active Job window



When the Active Job window reports that the load job is complete, click OK to return to the Load Job Select window.

Verify the transfer of data

You can use DB-Acess to verify that the data from /work/mydata was transferred into your database.

Perform a level-0 backup

The **onpload** utility does not log the data that it writes to a table during an express-mode load. For safety, **onpload** flags the dbspaces that are associated with the table as read-only. To allow for data recovery in case of disk corruption, you must make a level-0 backup. A level-0 backup on the dbspaces affected by the express-mode load saves the data and unsets the read-only flags.

If you do not care about data recovery, you can make a level-0 backup by using /dev/null as the backup device. This action unsets the read-only flag without backing up data to any real device.

The ipload utility Generate options

The **ipload** utility has Generate options that you can use to automatically create a format, map, query, and device. After the components are generated, you can modify the components to meet your needs.

This example uses the Generate button in the Unload Job window to create the components that are required for an unload job. After you create the components, you can use the Run option to run the unload job.

- Use the information you created with the ipload example
- Preparing the Unload Job window
  An unload job is a collection of the specific pieces of information that are required to move data from a database into a data file. The Unload Job window shows a flowchart that includes all of the components of an unload job. You can use the Generate option to create the components of the unload job and to complete the items on the Unload Job window.
- Performing the unload job
  You are now ready to perform the unload job.

Related reference:
The Generate options of the ipload utility

Use the information you created with the ipload example

If you completed the first example, your database server and **ipload** are ready for you to use. If you did not complete the example, you need to complete the following tasks as the first example describes:

- Start your database server (Prepare to use the ipload utility)
- Start **ipload** (Start the ipload utility)
- Check the defaults (Check the ipload utility default values)

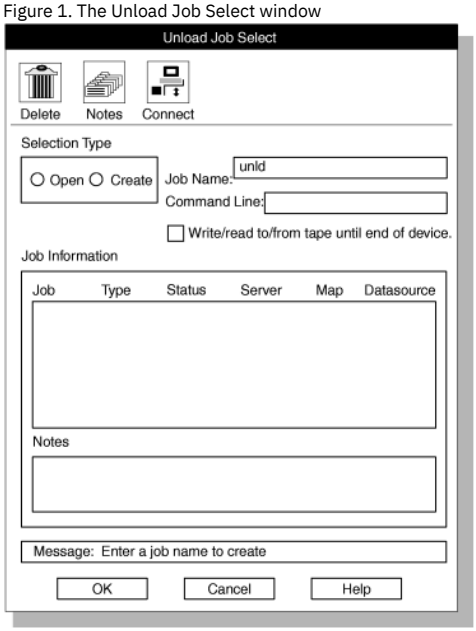
Preparing the Unload Job window

An unload job is a collection of the specific pieces of information that are required to move data from a database into a data file. The Unload Job window shows a flowchart that includes all of the components of an unload job. You can use the Generate option to create the components of the unload job and to complete the items on the Unload Job window.

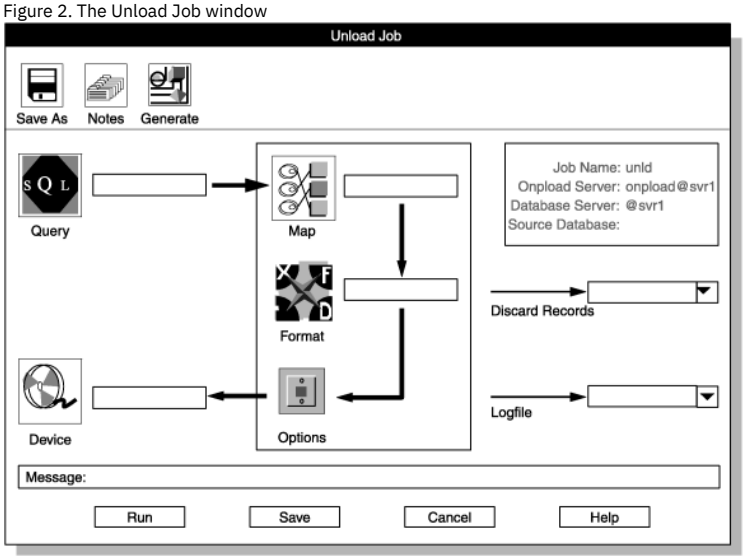
The generate example uses the Generate option to unload the contents of the **items** table of the **stores_demo** database into a file named /work/items_out. For instructions on how to create the **stores_demo** database and other demonstration databases, see the *IBM® Informix® DB-Access User's Guide*.

To generate the unload job:

1. Choose Jobs > Unload from the HPL window.
   The Unload Job Select window appears, as the following figure shows.
   Figure 1. The Unload Job Select window



2. Click Create in the Selection Type group.
3. Choose a name for the unload job and type it in the Job Name text box. This example uses the name **unld**.
4. Click OK.
   The Unload Job window appears, as the following figure shows. The information box in the upper right part of the display shows the name of the unload job, the name of the database server where the onpload database is stored, and the name of the database server where **ipload** is running.
   Figure 2. The Unload Job window



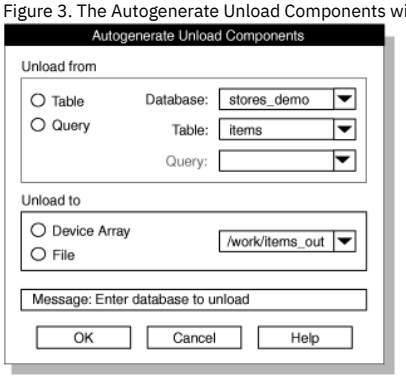
5. Click the Generate button.
   The Autogenerate Unload Components window appears. Figure 3 shows the completed window.

6. Click Table.

You can unload an entire database table or only selected records from the table. Table indicates that you want to unload the entire table. Query indicates that you want to unload selected records.

7. Type `stores_demo` in the Database text box.
   For this step and steps 8 and 10, you can click the down arrow to the right of the text box and select the entry from a selection list. Figure 2 shows an example of a selection list.

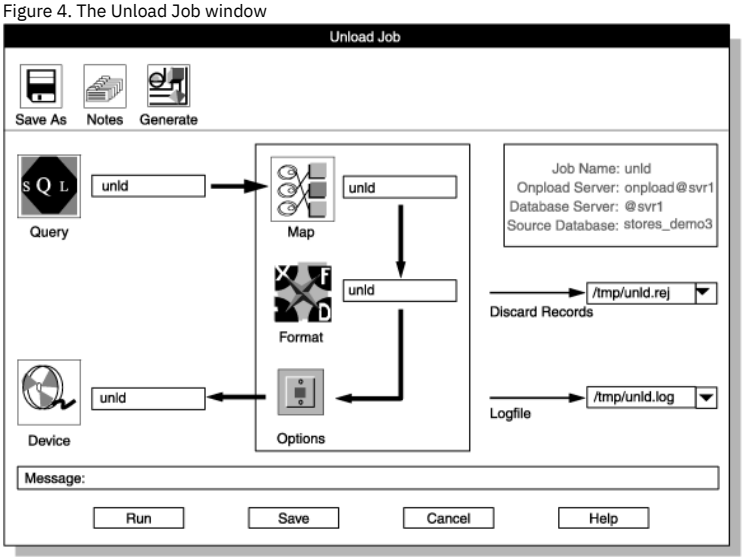
8. Type `items` in the Table text box.
   Figure 3. The Autogenerate Unload Components window



9. Click File.
   File indicates that you want to type the name of a file. If you choose Device Array, you must type the name of an existing device array.

10. Type the full path name of the file that will store the unloaded data. This file can be in any directory to which you have write access.
11. Click OK.

The Generate option creates the Query, Format, and Map components for the unload job and completes the Unload Job window. These components are all named **unld**.
The Generate option also creates a device array named **unld** and puts the file that you specified (/work/items_out) into that array.
Tip: After you finish this exercise, you can choose Components > Devices from the HPL window and examine the **unld** device array.
The following figure shows the Unload Job window as completed by the Generate option.
Figure 4. The Unload Job window



In addition to completing the main flow of the Unload Job window, the Generate option also enters the Source Database information in the upper right corner and creates path names for the Discard Records file and the Logfile. The HPL browsing options, describes the rejected records file and the log file.

Performing the unload job

You are now ready to perform the unload job.

Tip: You might want to preview the records that the query will select. See Preview data-file records.
To finish this example:

1. Click Save to save the unload job.
   After you save the unload job, the Message line displays the following message:

   ```
   Saved job successfully
   ```

   You can now run the job, or you can return at a later time and run the job.

2. Click Run to run the unload job.
   The Active Job window appears. This window reports the progress of your unload job. The Active Job window for an unload job is similar to the Active Job window for a load job, which Figure 1 shows.

3. When the Active Job window reports that the unload job is finished, click OK to return to the Unload Job window.
4. Click Cancel to return to the HPL main window.

5. You can create another job or choose Jobs > Exit to exit **ipload**.

The ipload utility windows

This section contains information about using the **ipload** utility.

- The ipload utility GUI or the onpladm command-line interface
  The **ipload** utility is a graphical user interface (GUI) that contains windows, buttons, online help, and keyboard commands. The **onpladm** command-line interface is equivalent to the **ipload** utility.
- The ipload utility GUI
- The HPL ipload utility buttons
  After you move beyond the main window, every window has at least one button to help you move through the interface.
- The HPL online help
  The Help menu on the High-Performance Loader (HPL) main window has Glossary and Contents choices.
- The UNIX keyboard commands to move the cursor
  Instead of using the mouse to move from area to area in the High-Performance Loader (HPL) user interface, you can use UNIX keyboard commands to move the cursor. As you move around, the currently selected item is highlighted with a box.

The ipload utility GUI or the onpladm command-line interface

The **ipload** utility is a graphical user interface (GUI) that contains windows, buttons, online help, and keyboard commands. The **onpladm** command-line interface is equivalent to the **ipload** utility.

- Start the ipload utility
  To start **ipload**, type `ipload` at the system prompt.

Related reference:
The onpladm utility

Start the ipload utility

To start **ipload**, type `ipload` at the system prompt.

A splash screen appears and stays on the display while **ipload** finishes loading. If you do not want to see the splash screen, use the **-n** flag with your command, `ipload -n`.

Related concepts:
The ipload utility

The ipload utility GUI

The **ipload** utility has the following types of displays:

- HPL main window
- Component-Selection windows
- Component-Definition windows
- Load Job and Unload Job windows
- Views windows
- Selection-List windows
- Message windows

Important: While the **onpload** and **onpladm** utilities include support for object names that contain up to 128 characters, the **ipload** utility does not. If you use long database, table or column names and create jobs by using **onpladm**, you cannot run these jobs by using **ipload**. For **ipload**, database, table, and column names cannot exceed 18 characters.

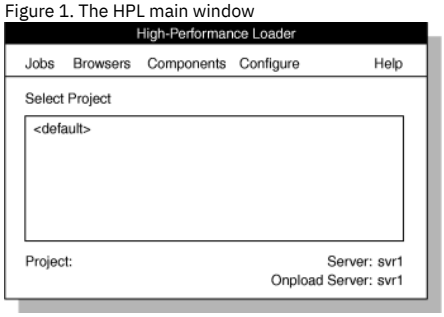
- The HPL main window
  When you start **ipload**, the High-Performance Loader (HPL) main window appears. The HPL main window is the focus of the user interface. You return to the main window after each task and choose a new option.
- Component-Selection windows
  The windows for creating or modifying components often (but not always) come in pairs. In the first window, the Component-Selection window, you can create a component or select an existing component to modify. You can also view notes and copy, delete, or print information about a component. In the second window, the Component-Definition window, you can make changes.
- Component-Definition windows
  After you select a component to create or modify and click OK in the Component-Selection window, you typically see the Component-Definition window. From the Component-Definition window, you can enter, edit, or delete values or items that describe the component.
- Load Job and Unload Job windows
  The Load Job and Unload Job windows provide a visual presentation of the basic components that you choose for each job.
- Views windows
  A Views window shows a graphic representation of the relationships among various **ipload** components. From a Views window, you can search for specific components, select an existing component for editing, or create a component.

- Selection-List windows
  A Selection-List window lists the possible values for a text box. A down arrow that follows a text box indicates that you can use a selection list to see and select possible values for the text box. When you click the down arrow, the corresponding Selection-List window appears.
- Message windows
  A message window typically contains either a warning or an information update. A warning lets you verify or cancel the action that you have chosen. An update informs you about the successful completion of an operation or explains why an operation failed.

The HPL main window

When you start **ipload**, the High-Performance Loader (HPL) main window appears. The HPL main window is the focus of the user interface. You return to the main window after each task and choose a new option.

Figure 1. The HPL main window



- Initial options on the HPL main window
- Options of the HPL main window
  After you select a project, you can choose options from any of the menus on the HPL main window.

Initial options on the HPL main window

When you first enter **ipload**, you can:

- Select the default project in the Select Project list.
- Choose Configure > Project to create a project.
- Choose Configure > Server to select a database server and an onpload database server.
- Choose **Help** to look at the online help.
- Choose Jobs > Exit to exit from **ipload**.

Related concepts:
Select a database server
Related tasks:
Defining a new project

Options of the HPL main window

After you select a project, you can choose options from any of the menus on the HPL main window.

The following table shows the options of the main menu:

Table 1. HPL main menu and submenu options

Main menu option	Submenu option	Purpose	See
Jobs	Load	Create a load job and use the Load Job window to load data into a database.	Load data to a database table
Jobs	Unload	Create an unload job and use the Unload Job window to unload data from a database to a file.	Creating an unload job
Jobs	Exit	Exit from the user interface.	The ipload utility
Browsers	Record	Review records in a specified format, search the list of available formats, or edit a format.	Reviewing records that the conversion rejected
Browsers	Violations	View records that passed the filter and conversion but were rejected by the database.	Viewing the violations table
Browsers	Logfile	View load status and see where any errors occurred.	View the status of a load job or unload job
Components	Formats	Create or modify data-file formats.	Define formats
Components	Maps	Create or modify maps that show the relationship between data-file fields and database columns.	Define maps
Components	Query	Build, modify, or retrieve SQL-based queries.	HPL queries

Main menu option	Submenu option	Purpose	See
Components	Filter	Create or modify filters that determine source data-file records for conversion and load.	Define filters
Components	Devices	Specify a set of files, tapes, or pipes (UNIX only) that will be read simultaneously for loading or unloading the database.	Define device arrays
Components	Generate Job	Automatically generate the components for load and unload jobs.	The Generate options of the ipload utility
Configure	Server	Select the database servers that hold the onpload database and the target database.	Configure the High-Performance Loader
Configure	Project	Create a project under which formats, filters, queries, maps, and load and unload jobs are stored.	Define HPL projects
Configure	Defaults	Specify the default character sets for the data file and databases.	Modify the onpload default values
Configure	Machines	Specify the machine parameters that are used to convert binary data.	Modify the machine description
Help	Glossary	View definitions of terms that pertain to the HPL.	The HPL online help
Help	Contents	View the main contents page that directs you to discussions of various HPL topics.	The HPL online help

Component-Selection windows

The windows for creating or modifying components often (but not always) come in pairs. In the first window, the Component-Selection window, you can create a component or select an existing component to modify. You can also view notes and copy, delete, or print information about a component. In the second window, the Component-Definition window, you can make changes.

The details of a selection window vary depending on the operation that you are performing.

The following figure shows the Device Array Selection window to illustrate the standard features of Component-Selection windows.
Figure 1. The Device Array Selection window

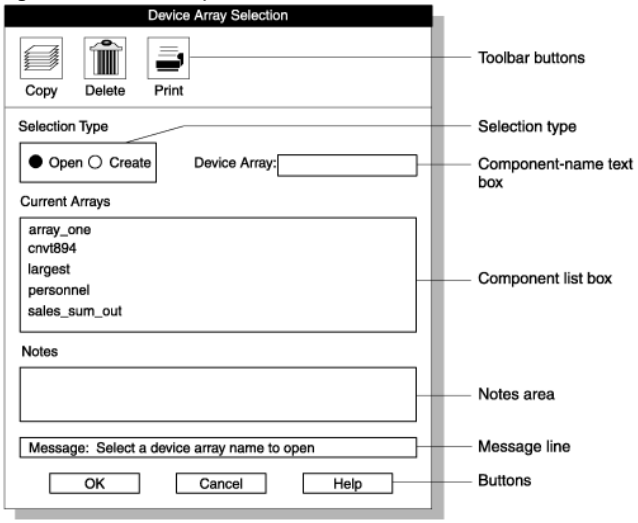


Table 1. The Device Array Selection window options

Display option	Description
Toolbar buttons	The buttons across the top of the display represent actions that you can take after you select a component from the component list. For example, in Figure 1, the toolbar buttons indicate that you can copy, delete, or print an array. The HPL ipload utility buttons explains how to use these buttons.
Selection type	The selection type allows you to specify the action that you want to take. In most of the displays, you can either open an existing component or create a component.
Component-Name text box	If you click Create, you must type a name for the new component in the Device-Array text box. (In Figure 1, you must give a name for the new device array.)
Device Array text box	Before you can type a name in the Device Array text box, you must click inside that text box to activate it. When the text box is active, it has a narrow black border. If you type a character that is not valid, the interface beeps at you, displays a message on the message line, and refuses to display the invalid character.
Component list box	The component list box lists the components that currently exist in this project. If you click Open in the selection group, you must select a component from this list.
Notes area	The notes area displays stored comments about the selected component. This area is not an active area. To store a comment about a component, you must select a component and use the Notes button. For more information about notes, see The Notes button.
Message Line	The message line primarily gives instructions for the next logical action. The message line also gives an error message when an action fails or a completion message when a process is finished.
Buttons	The buttons across the bottom of the display let you indicate your next action. For a more complete discussion, see The HPL ipload utility buttons.

Component-Definition windows

After you select a component to create or modify and click OK in the Component-Selection window, you typically see the Component-Definition window. From the Component-Definition window, you can enter, edit, or delete values or items that describe the component.

The following figure shows an example of a Component-Definition window: the Device-Array Definition window.
Figure 1. The Device-Array Definition window

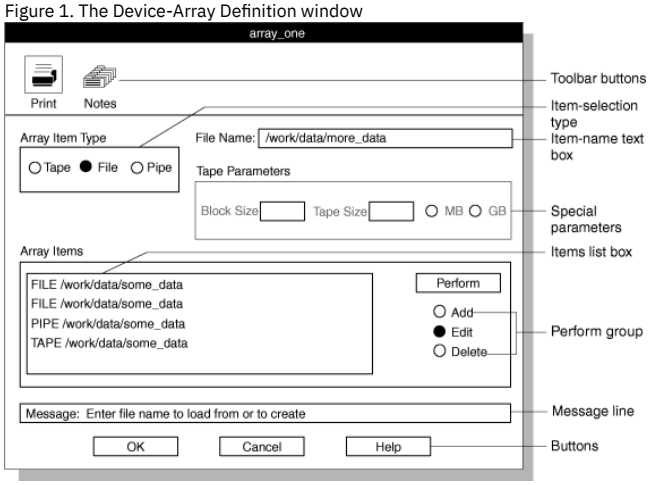

Table 1. The Device-Array Definition window options

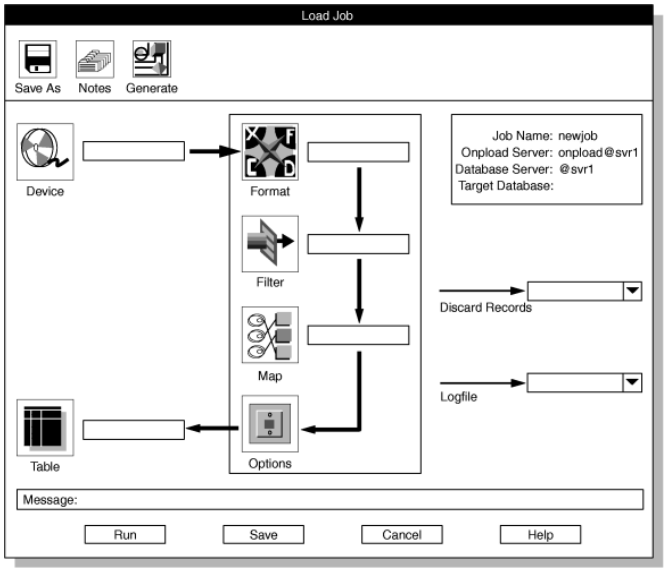
Display option	Description
Toolbar buttons	The buttons across the top of the display represent actions that you can take after you select a component from the component list box. For example, in Figure 1 (the Device-Array Definition window), the toolbar buttons indicate that you can print or make a note about an item. The HPL ipload utility buttons explains how to use these buttons.
Item-selection group	The item-selection group lets you specify the type of item that you want to edit or the type of action that you want to take. After you specify a choice in the item-selection group, other options become active. In the Device-Array Definition window, the item-selection group is labeled Array Item Type. After you select Tape, File, or Pipe (only on UNIX), other options become active.
Item-name text box	The item-name text box lets you specify the name or description of one of the items that makes up the component. For example, in the Device-Array Definition window, you type the full path name of a device in the item-name text box. In the Device-Array Definition window, the item-name text box is labeled Tape Name, File Name, or Pipe Name (only on UNIX), depending on the type of component that you select from the Array Item Type group.
Special-parameters group	When a Component-Definition window first appears, some of the choices are inactive (shown in gray letters). In general, the inactive choices are not meaningful until you specify some other characteristic of the component that you are editing. The special-parameters group in the Device-Array Definition window is the Tape Parameters group. The items in the special-parameters group are meaningful only for tapes. The choices in the **Tape Parameters** group become active only if you select **Tape** from the **Array Item Type** group. The choices in Figure 1 are gray because File is selected in the Array Item Type group.
Item list box	The item list box shows items that you already created to define the component. In the Device-Array Definition window, this list is labeled Array Items and shows the tapes, files, and pipes (UNIX only) that are already part of the current device array.
Perform group	The Perform group lets you specify the action that you want to take. After you select an item and an action, you must click Perform to complete the action. For example, to add a new device in the Device-Array Definition window, you must specify the name or description of the device and then click Perform to add it to the Array List. Important: Remember to click Perform to complete the action that you designated in the Perform group.
Message line	The message line primarily gives instructions for the next logical action. The message line also returns an error message when an action fails or a completion message when a process is finished.
Buttons	The buttons across the bottom of the display let you indicate your next action. For a more complete discussion, see The HPL ipload utility buttons.

Load Job and Unload Job windows

The Load Job and Unload Job windows provide a visual presentation of the basic components that you choose for each job.

The following figure shows the Load Job window.
Figure 1. The Load Job window



Related reference:
Unload data from a database
Load data to a database table

Views windows

A Views window shows a graphic representation of the relationships among various **ipload** components. From a Views window, you can search for specific components, select an existing component for editing, or create a component.

A Views window does not allow you to change any values. To change the values of a component, you must display a Component-Definition window.

- Access views windows
- Available options in a Views window

Access views windows

The following table lists the four types of views windows and gives instructions for how to access each view.

Window name	Purpose	How to access	See
Format Views	Shows the load and unload maps that are associated with a particular format	• Click Search in the Record Formats window • Click Format in the Load Job window* • Click Format in the Unload Job window*	Figure 1
Map Views	Shows the databases, tables, queries, and formats that are associated with a map	• Click Search in the Load Record Maps window • Click Search in the Unload Record Maps window • Click Map in the Load Job window* • Click Map in the Unload Job window*	Figure 1
Database Views	Shows the tables in the database or the queries that are associated with the database	• Click Search in the Query window • Click Table in the Load Job window* • Click Query in the Unload Job window*	Figure 1
Filter Views	Shows the formats that are associated with a particular filter	• Click Search in the Filter window • Click Filter in the Load Job window*	Filter views

* These options display the Views window only if the corresponding text box is empty. If the text box includes the name of a component, the Component-Definition window is displayed.

Available options in a Views window

The four types of Views windows operate in a similar manner. When a Views window appears, you have the following options:

- Type in a component name and search for the component.
- Click a label associated with an icon to expand the view and see related components.
- Click an icon to open the Component-Definition window that allows you to edit the component values.
- Click Create to display the Component-Selection window that allows you to create a component.

- Search for a component in a Views window
  You can use the Search button in a Views window to locate a specific component.

- Expand the view in a Views window
  Three of the Views windows expand their views to show related components.

Search for a component in a Views window

You can use the Search button in a Views window to locate a specific component.

Type the component name in the search text box and then click Search. The view displays only the component names that match the text string.

You can use the following wildcard search characters in the search text string.

Table 1. Wildcard search characters

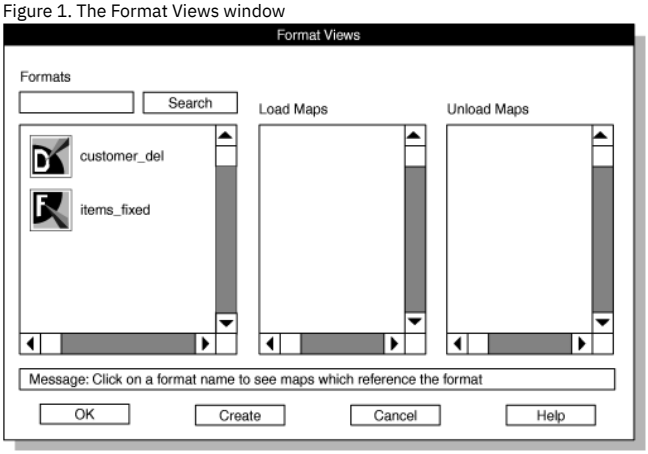
Wildcard symbol	Effect
?	Matches any single character
*	Matches any string of characters

Expand the view in a Views window

Three of the Views windows expand their views to show related components.

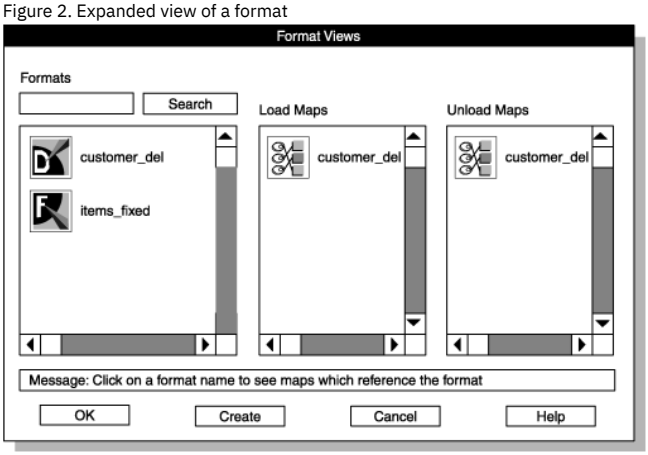
To expand the view, click an icon label (for example, **customer_del**) in the first pane. In the Database Views window, click an icon label in the second pane to expand the view further. The following figure shows the Format Views window.

Figure 1. The Format Views window



When you click an icon label in the **Formats** pane, the view expands to show maps that are related to your choice. The following figure shows the expanded view.

Figure 2. Expanded view of a format



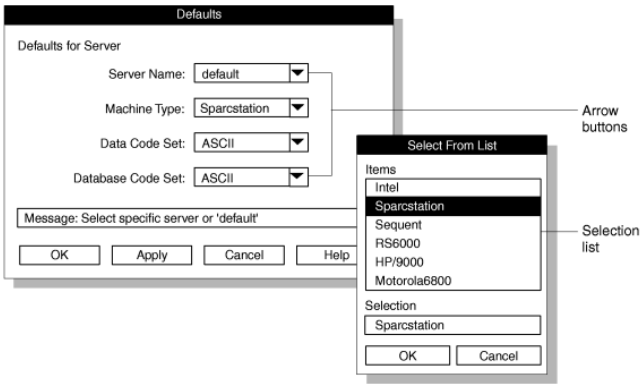
You can click the icon that you want to display a definition window for any format or map that is shown.

Selection-List windows

A Selection-List window lists the possible values for a text box. A down arrow that follows a text box indicates that you can use a selection list to see and select possible values for the text box. When you click the down arrow, the corresponding Selection-List window appears.

The following figure shows the selection list that is available for the Machine Type text box in the Defaults window. After you select an item in the list box, click OK, and the item appears in the text box on the original window.

Figure 1. The Defaults window and a selection list

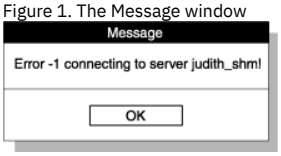


Tip: If your entry is rejected, look at the selection list. Your entry is invalid if it is not available in the selection list.
Selection-List windows are available for many text boxes throughout the HPL user interface. These windows have various names, but these topics refer to them as selection lists.

Message windows

A message window typically contains either a warning or an information update. A warning lets you verify or cancel the action that you have chosen. An update informs you about the successful completion of an operation or explains why an operation failed.

The following figure shows a typical error message.
Figure 1. The Message window



The HPL ipload utility buttons

After you move beyond the main window, every window has at least one button to help you move through the interface.

In general, buttons appear in three locations:

- Toolbar buttons appear across the top of the display.
- Icon buttons appear in the middle section of the display.
- Buttons appear across the bottom of the display.

- The HPL ipload utility toolbar buttons
  Toolbar buttons appear at the top of many windows. The function of the window determines which buttons appear.
- The HPL ipload utility icon buttons
  Icon buttons appear in the middle sections of the Load Job, *Unload Job*, and Views windows. The icon buttons represent various components. When you click it, each button opens another display.
- Buttons at the bottom of the HPL ipload utility display
  The buttons across the bottom of the display let you indicate the next action. Most windows have one or more of these buttons.

The HPL ipload utility toolbar buttons

Toolbar buttons appear at the top of many windows. The function of the window determines which buttons appear.
The following sections describe the toolbar buttons. Buttons that appear in only one window are described with the specific window.

Button	Button name	Purpose	See
	Browse	Displays the Browse window	The HPL browsing options
	Copy	Copies the selected component (format, map, query, filter, device, or project) to a new item	The Copy button
	Connect	Lets you reattach to an active unload (or load) job from the Unload (or Load) Job Select window	Figure 1
	Delete (trash can)	Deletes the selected component (format, map, and so on)	The Delete button
	Delete (eraser)	Breaks the association between a database column and a data-file field	Using the Delete button
	File	Displays the Import/Export File Selection window	Exporting and importing queries
	Find	Allows you to quickly locate a particular field or column in a Map window	Using the Find button

Button	Button name	Purpose	See
	Generate	Lets you generate jobs automatically	The Generate options of the ipload utility
	Notes	Allows you to type descriptive text for an item	The Notes button
	Options	Displays an options window where you can change default values or supply additional parameters	Changing the unload options, Changing the load options
	Print	Prints the parameters for the selected item	The Print button
	Save As	Saves a copy of the currently selected item (behaves in the same way as the Copy button)	The Copy button
	Search	Displays a Views window where you can see the relationships among components	Views windows
	Specs	Displays the Specifications window, where you can view the attributes for selected columns or fields	Using the Specs button

- The Browse button
  With the Browse button, you can look through the files that show information about the load or unload jobs and any problems that the **onpload** utility found.
- The Copy button
  You can copy a selected component with the Copy button. This feature can save you time when you are creating a component. You can copy an existing component and then modify the copy with your changes.
- The Delete button
  The Delete button lets you delete one or more selected components.
- The Notes button
  You can type descriptive text for an item with the Notes button. The text of the note is displayed in the Notes area in a window when you select the item. The Notes button is a useful tool for identifying **ipload** components, load jobs, unload jobs, and projects.
- The Print button
  You can print information that is associated with a component with the Print button. Before you start **ipload**, you must set your workstation so that it can find a printer.

The Browse button

With the Browse button, you can look through the files that show information about the load or unload jobs and any problems that the **onpload** utility found.

Related concepts:
Browsing options

The Copy button

You can copy a selected component with the Copy button. This feature can save you time when you are creating a component. You can copy an existing component and then modify the copy with your changes.

You can copy one component at a time, or you can select and copy multiple components at the same time. You can copy components that are grouped under a project (filters, formats, maps, and queries) within the same project, or to a different project.

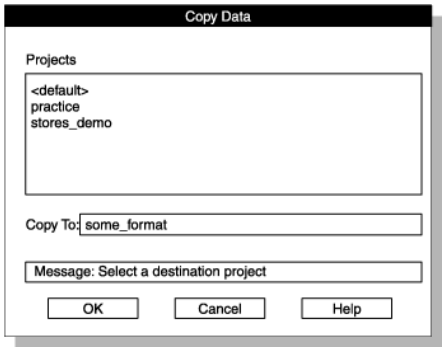
If you copy a component within a project, you must give the copy a different name. If you copy a component to a different project, you can retain the name for the copy or give the copy a different name. If you copy multiple components, you must copy them to a different project. When you copy multiple components, the components retain their names.
Important: Devices are not project specific. When you copy a device, you must give the copy a new name.

- Copying an existing format into a new format

Copying an existing format into a new format

To copy an existing format to a new format:

1. In the HPL main window, select the project that includes the format that you want to copy.
2. Choose Components > Formats to access the Record Formats window. For an example, see Creating a fixed format.
3. Select the format that you want to copy. This example assumes that the format to copy is **some_format**.
4. Click the Copy button.
   The Copy Data window appears, as the following figure shows. The Copy Data window displays a list of existing projects. The Copy To text box shows the name of the format that you are copying.
   Figure 1. The Copy Data window



5. Select the project to which you want to copy the format.
6. Type the name that you want to give to the copied format in the Copy To text box.
   If you are copying the format to another project, you can keep the same name. You must change the name, however, if you are copying the format to the same project.
7. Click OK. The display returns to the Record Formats window.
8. Click Cancel to return to the HPL main window.

The Delete button

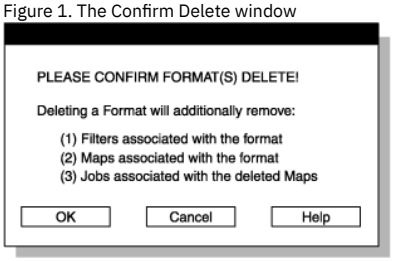
The Delete button lets you delete one or more selected components.

- Deleting an existing format

Deleting an existing format

To delete an existing format:

1. In the HPL main window, select the project that includes the format that you want to delete.
2. Choose Components > Formats to access the Record Formats window. For an example, see Creating a fixed format.
3. Select the format that you want to delete.
4. Click the Delete button.
   The Confirm Delete window appears, as the following figure shows. The Confirm Delete window describes the impact of deleting this format. The text in this window is different for each of the component types.
   Figure 1. The Confirm Delete window



5. Click OK to confirm the deletion, or click Cancel to cancel it.
   If you click OK, the format is deleted and any associated maps, filters, and jobs.
6. Click Cancel to return to the HPL main window.

The Notes® button

You can type descriptive text for an item with the Notes button. The text of the note is displayed in the Notes area in a window when you select the item. The Notes button is a useful tool for identifying **ipload** components, load jobs, unload jobs, and projects.

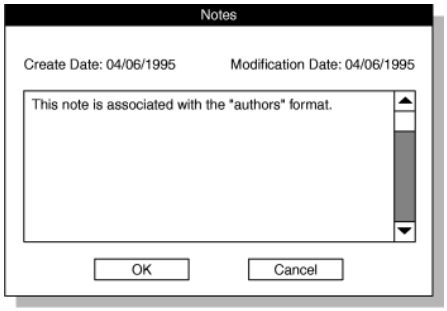
- Creating a note

Related reference:
The note table in the onpload database

Creating a note

To create a note:

1. Click the Notes button in a Component-Definition window.
   The Notes window appears, as the following figure shows.
   Figure 1. The Notes window

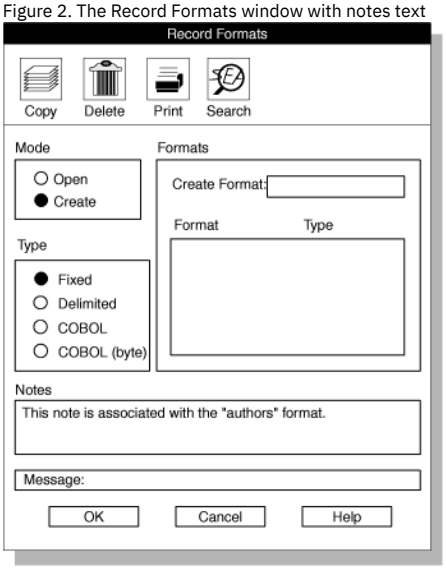


2. Type the descriptive text in the Notes text box.
3. Click OK to store the note and return to the Component-Definition window.
   When you select the component, the note text is displayed in the Notes area.

If you do not change a note, click Cancel instead of OK.

For example, the note created in the Notes window is associated with the **authors** format. The next time you go to the Record Formats window and select authors, **ipload** displays the note text, as the following figure shows.

Figure 2. The Record Formats window with notes text



The **ipload** utility stores the information that you type in the **note** table window of the onpload database. For a description of the **note** table, see The note table in the onpload database.

The Print button

You can print information that is associated with a component with the Print button. Before you start **ipload**, you must set your workstation so that it can find a printer.

For information about setting up a printer, see your operating-system publications.

If you click the Print button in the Map-Definition window in Figure 2, the following printout results:

```
--------------------------------------------------------------------------------
LOAD MAP REPORT
--------------------------------------------------------------------------------

Project : <default>
Name: a_map

OPTIONS
 Database Table  Format
 -------- ---------  --------------
 testdbtab1a_format

RECORD FORMAT MAP VIEW
 Format FieldTable Column Option Data
 ----------------------  -------------------  ------------------
 input1  col3
 input2  col2
 input3  col1
```

The HPL ipload utility icon buttons

Icon buttons appear in the middle sections of the Load Job, *Unload Job*, and Views windows. The icon buttons represent various components. When you click it, each button opens another display.

The following table shows and describes the icon buttons that are used in these windows.

Component	Description	Window	Action
 Device	The device or device array where the source files are located	Load Job, Unload Job	• If the text box is empty, click the Device button to display the Device Array Selection window, where you can create or open a device type. • If the text box has an entry, click the Device button to display the Device Array Selection window for that specific device or type the name of a different device in the text box.
 Filter	The filter that controls which records are selected from the data file for a database update (The use of a filter is optional.)	Load Job, Filter Views	• If the text box is empty, click the Filter button to display the Filter Views window, where you select a filter and associated format. You can also create a filter from this window. • If the text box has an entry, click the Filter button to display the Filter-Definition window for that specific filter or type the name of a different filter in the text box. • In the Filter Views window, click the Filter button to display the Filter-Definition window for a specific filter.
 Format	The format of the source data used for this load or unload	Load Job, Unload Job	• If the text box is empty, click the Format button to display the Format Views window, where you can select a format and associated map. You can also create a format from this window. • If the text box has an entry, click the Format button to display the Format-Definition window for that specific format or type the name of a different format in the text box. • In all Views windows, click the Format button to display the format definition for a specific format. In these windows, the button shows only one of the three symbols (F, D, C) to indicate whether the type of format is fixed, delimited, or COBOL.
 Map	The map that correlates fields of the data source to database columns	Load Job, Unload Job, Map Views, Format Views, Database Views	• If the text box is empty, click the Map button to display the Map Views window, where you can select a map and associated table and format. You also can create a map from this window. • If the text box has an entry, click the Map button to display the Map-Definition window for that specific map or type the name of a different map in the text box. • In a Views window, click the Map button to display the Map-Definition window for a specific map.
 Options	The options that let you specify characteristics of the load or unload	Load Job, Unload Job	• Click the Options button to display the Load Options window.
 Query	The query that selects data from the database table	Unload Job, Database Views, Map Views	• If the text box is empty, click the Query button to display the Database Views window from which you can select the table and associated map and format. • If the text box has an entry, click the Query button to display the Query-Definition window for that specific query or type the name of a different query in the text box. • In a Views window, click the Query button to display the Query-Definition window for a specific query.
 Table	The database table into which the converted data will be loaded	Load Job, Database Views, Query Definition	• Click the Table button to display the Database Views window from which you can select the table and associated map and format. If an association is not apparent, click Create to create one. • Click the Table button in the Query-Definition window to choose a table and columns for the Select entry.

Related tasks:
Changing the load options

Buttons at the bottom of the HPL ipload utility display

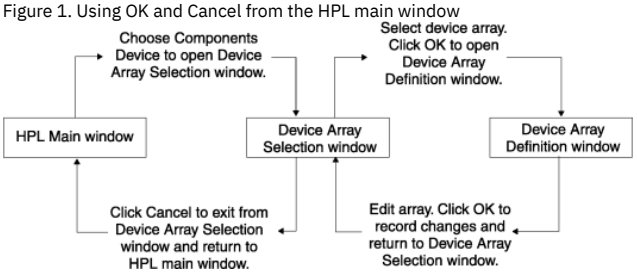
The buttons across the bottom of the display let you indicate the next action. Most windows have one or more of these buttons.

Table 1. Buttons that indicate the next action

Button name	Action
Apply	Saves changes but does not exit.
Cancel	Does not save any changes. Exit to the previous display.
Create	Displays the Component-Selection window.
Help	Displays context-sensitive help in a separate window. For information about the online help, see The HPL online help.
OK	Save changes and exit to the previous display.

Use OK only when you have changed the display. If you are exiting from a series of displays, use Cancel to exit from the display. The following figure shows the use of OK and Cancel.

Figure 1. Using OK and Cancel from the HPL main window



The HPL online help

The Help menu on the High-Performance Loader (HPL) main window has Glossary and Contents choices.

The **Glossary** option opens a scrolling list of items. Select an item to see its definition. The **Contents** option takes you to the main contents page. This page directs you to discussions of various HPL topics.

If you click Help in any window other than the HPL main window, Help displays information that is related to the current window. After the Help window opens, you can click its Help button for more information about using the Help window.

The UNIX keyboard commands to move the cursor

Instead of using the mouse to move from area to area in the High-Performance Loader (HPL) user interface, you can use UNIX keyboard commands to move the cursor. As you move around, the currently selected item is highlighted with a box.

The following table lists the cursor-moving keystrokes.

Table 1. Cursor moving keystrokes

Keystroke	Result
TAB	Move from area to area. Sometimes used to move from tab stop to tab stop.
SHIFT-TAB	Back up; that is, move from area to area in reverse order.
CONTROL-TAB	Move from area to area when `TAB` is reserved to move from tab stop to tab stop.
Cursor keys	Move from item to item within a functional area.
SPACEBAR	Select the current item or action.

Most displays in the HPL user interface are divided into functional areas, such as toolbar buttons, selection group, component-name text box, component list box, and so on. Depending on the nature of the specific display, sometimes `TAB` moves from item to item (or even from tab stop to tab stop) within a major area. On other displays, `TAB` moves only between functional areas, and you must use `SPACEBAR` to move around within the functional area.

Define HPL projects

This section explains how to create a project and how projects are related. The individual components that you store in projects are described in later sections.

- HPL projects
  You can organize your work by specifying *projects* with the High-Performance Loader (HPL). A project is a collection of individual pieces that you use to load and unload data. A project can include load and unload jobs and the maps, formats, filters, and queries that you use to build the load and unload jobs.
- Project organization
  The High-Performance Loader (HPL) uses only one database, onpload, to track the preparation that you do for loading and unloading data. By using projects, you can organize your work into functional areas.
- Select or create a project with the Projects window
  You can select or create a project from the Projects window. After you select a project, you can copy the project, delete it, print the project parameters, or make a note that describes the project.

Related reference:
Choose a project

HPL projects

You can organize your work by specifying *projects* with the High-Performance Loader (HPL). A project is a collection of individual pieces that you use to load and unload data. A project can include load and unload jobs and the maps, formats, filters, and queries that you use to build the load and unload jobs.

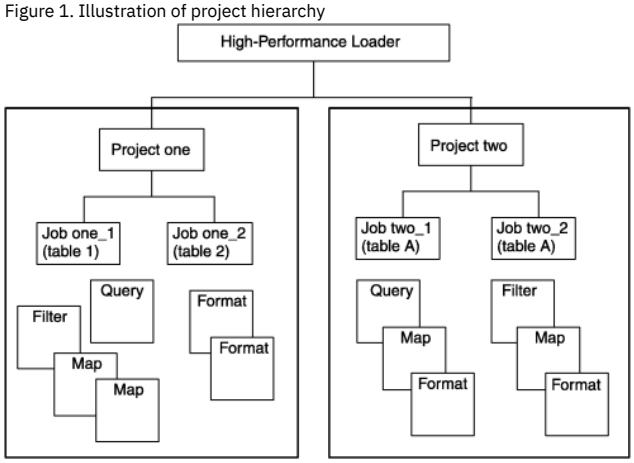
Project organization

The High-Performance Loader (HPL) uses only one database, onpload, to track the preparation that you do for loading and unloading data. By using projects, you can organize your work into functional areas.

For example, you might regularly transfer data to or from several unrelated databases. You could put all of the preparation for each database into a separate project.

When you first start **ipload**, **ipload** creates a project named **<default>**. If you prefer, you can select the **<default>** project and assign all of your work to that project. The HPL does not require that you create any additional projects. However, creating projects and putting separate tasks into distinct projects makes your work easier to maintain.

The following figure shows the relationships among projects, jobs, and components.
Figure 1. Illustration of project hierarchy



The preceding figure shows that jobs are linked directly to the projects. The format, map, filter, and query components belong to a project but are not directly linked to a job, as illustrated with Project One. In general, you create a format, map, and filter or query for each job, as shown with Project Two. However, in some cases, you might use the same component for more than one job within a project.

For example, for reports about a medical study, you might want to create three reports: one about subjects under 50 years of age, one about subjects over 50, and one about all subjects. In that case, the description of how to find the information (the format and map) is the same for all three reports, but the selection of information (the query) is different for each report. (Formats, maps, and queries are described in detail in later chapters.)

All components (maps, formats, queries, filters, and load and unload jobs) that you create in a project are associated with that project in the onpload database. Components that are associated with a project are visible (usable) only when the project is selected. When you select a different project, a different set of components becomes available.

Device-array definitions and configuration parameters are not included in project definitions. The following figure shows the components that the HPL uses. Each project is distinct, but the devices and configuration parameters apply to all projects.
Figure 2. Relationship of projects, devices, and configuration parameters

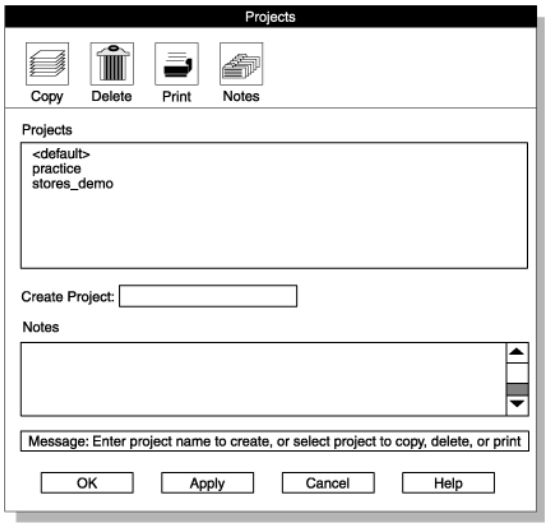
Define projects
The project table in the onpload database

Select or create a project with the Projects window

You can select or create a project from the Projects window. After you select a project, you can copy the project, delete it, print the project parameters, or make a note that describes the project.

The **ipload** utility stores project information in the **project** table of the onpload database.
Figure 1. The Projects window



- Defining a new project
- Selecting a project
  The HPL provides two methods for selecting a project.

Related reference:
The project table in the onpload database

Defining a new project

To define a new project:

1. Choose Configure > Project from the HPL main window.
   The Projects window appears, as Figure 1 shows.
2. Choose a name for the project and type it in the Create Project text box.
3. Click Apply.
   The **ipload** utility creates the project but does not exit from the Projects window. You can create another project, or you can use the toolbar buttons to manipulate the project.
4. Click Cancel to return to the HPL main window.

If you want to create one project and then exit, click OK instead of Apply.

Related concepts:
Initial options on the HPL main window

Selecting a project

The HPL provides two methods for selecting a project.

- Selecting a project for a load or unload job
- Selecting a project to edit

Selecting a project for a load or unload job

To select a project for a load or unload job or to edit components:

1. Select the project name from the Select Project list box in the HPL main window.
2. Choose the action that you want to take from one of the menus on the HPL main window.

Selecting a project to edit

To select a project to edit:

1. Choose Configure > Project from the HPL main window.
   The Projects window appears, as Figure 1 shows.
2. Select the project that you want to edit from the Projects list box.
3. Perform the edit actions (copy, delete, print, or describe with a note) you want.

4. Click Cancel to return to the HPL main window.

Configure the High-Performance Loader

This section describes the process of configure the High-Performance Loader (HPL).

- Configure the ipload utility
  When you configure the **ipload** utility, you describe the type of computer, code sets, and other aspects of your database server environment. Configuration information is stored in the **onpload** database.
- Select a database server
  The High-Performance Loader (HPL) needs to know the location of two databases: the onpload database and the *target database*.
- Modify the onpload default values
  You must describe the computer environments of your database servers. This information applies to database servers. If you change the description of a database server, the changes apply to all jobs that you run on that database server. You can prepare a default computing environment that applies to all database servers that are not explicitly described.
- Selecting a driver
- Modify the machine description
  The information that the Machines option of the Configure menu stores describes the characteristics of a specific computer. The High-Performance Loader (HPL) uses these characteristics to control the conversion of binary data formats. Unless you are converting binary data, you do not need to be concerned about the machine description.

Related reference:
Check the ipload utility default values

Configure the ipload utility

When you configure the **ipload** utility, you describe the type of computer, code sets, and other aspects of your database server environment. Configuration information is stored in the **onpload** database.

The configuration tasks include:

- Selecting a database server
- Modifying the onpload defaults
- Selecting or creating a driver
- Modifying the machine description

Related concepts:
The ipload utility
Related reference:
HPL performance

Select a database server

The High-Performance Loader (HPL) needs to know the location of two databases: the onpload database and the *target database*.

The target database is the IBM® Informix® database into which you load data or from which you unload data. When you start **ipload**, **ipload** assumes that both the onpload database and the target database are on the database server that the INFORMIXSERVER environment variable specifies. You can use the Connect Server window (Figure 1) to specify different database servers.

The sqlhosts file or registry controls connectivity to database servers. The **ipload** utility scans the sqlhosts information to derive the lists of available database servers that the Connect Server window displays.
Restriction: You cannot use the alias **loghost** as a machine name in the sqlhosts file. The **loghost** alias is present on all computers; consequently, onpload cannot correctly identify computers based on this name.

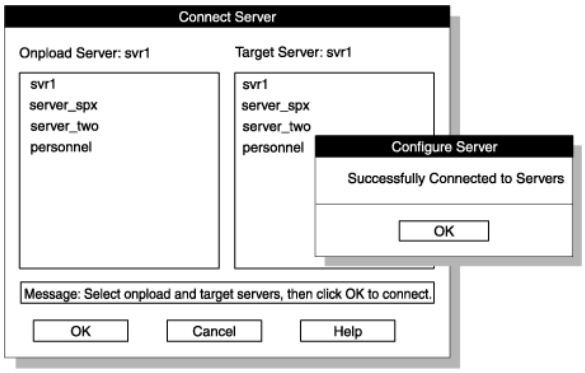
- Selecting a database server
- Create the onpload database
  When you first start **ipload**, **ipload** creates an onpload database. If you use the Connect Server window to choose a different onpload database server, **ipload** creates another onpload database on that database server.

Related concepts:
Initial options on the HPL main window

Selecting a database server

To select a database server:

1. Choose Configure > Server from the HPL main window.
   The Connect Server window appears, as the following figure shows.
   Figure 1. The Connect Server window



2. Select the database server where the onpload database is going from the Onpload Server list box.
3. Select the database server that includes the database that you will load or unload from the Target Server list box.
4. Click OK.
5. Click OK in the Configure Server window to return to the HPL main window.

Create the onpload database

When you first start **ipload**, **ipload** creates an onpload database. If you use the Connect Server window to choose a different onpload database server, **ipload** creates another onpload database on that database server.

The default name of the database that the High-Performance Loader (HPL) uses is onpload. To give some other name to the HPL database, set the DBONPLOAD environment variable.

Related tasks:
Preparing multiple onpload databases

Modify the onpload default values

You must describe the computer environments of your database servers. This information applies to database servers. If you change the description of a database server, the changes apply to all jobs that you run on that database server. You can prepare a default computing environment that applies to all database servers that are not explicitly described.

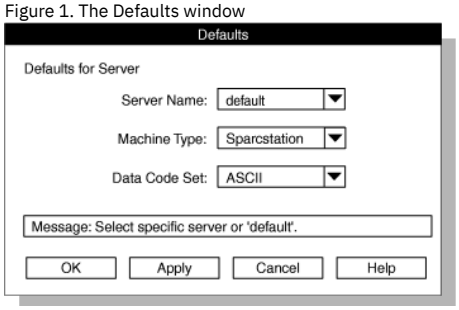
- The Defaults window
  You can change the server name, machine type, and data code set from the Defaults window.
- Specifying the onpload defaults

Related reference:
Look at the Defaults window
The defaults table in the onpload database

The Defaults window

You can change the server name, machine type, and data code set from the Defaults window.

The following figure shows the Defaults window.
Figure 1. The Defaults window



The **ipload** utility saves the information from the Defaults window in the **defaults** table of the onpload database. For more information about the **defaults** table, see The defaults table in the onpload database.
Tip: You can use DB-Acess to examine the default values. The following tables in the onpload database contain default values: **defaults**, **delimiters**, **driver**, and **machines**.

Table 1. The Defaults window options

Display option	Header

Display option	Header
Server Name	The Server Name text box specifies the database server with which the settings are associated. The information provided for the special server name **default** applies to all database servers for which no explicit information is provided. For example, if most the database servers on your network (that will be using the HPL) are BrandX computers, **default** should describe the BrandX computers. To describe the computing environment of the other database servers on the network, specify the database server name. The selection list that is associated with the Server Name text box lists the database servers that are identified in the sqlhosts information.
Machine Type	The Machine Type text box describes fixed-length, binary-format records. It defines the sizes and byte order of data in data files that the specified database server produces. The selection list that is associated with the Machine Type text box provides descriptions of several computers. You can use the Machines option on the Configure menu to add descriptions of other computers to this list (see Modify the machine description).
Data Code Set	The Data Code Set text box specifies the character set of the data file. When you load data into a database, you can convert the character set of the data file into the character set of the database. For example, you can convert EBCDIC to ASCII, or any other character set that your system supports. Conversely, you can convert the data from a database into a selected character set when you unload data. You can select the GLS code set you want from this selection list. The character set of the database is determined by the DB_LOCALE environment variable. For information about locales and code sets, see the *IBM® Informix® GLS User's Guide*.

Specifying the onpload defaults

To specify defaults for onpload:

1. Choose Configure > Defaults from the HPL main window.
   The Defaults window appears, as Figure 1 shows.
2. Update the values in each of the text boxes. Click the down arrows to display selection lists that show possible values for each text box.
3. Click Apply to save the values and prepare the defaults for another database server.
4. Click Cancel to return to the HPL main window.

If you want to prepare the defaults for only one database server, click OK instead of Apply.

Related concepts:
Modify the machine description

Selecting a driver

In a UNIX environment, you can use pipe-device arrays to connect custom programs to the input or output of the **onpload** utility. Although pipe-device arrays provide the simplest way to customize the input or output of **onpload**, connecting the standard I/O of programs is less efficient than directly incorporating the functionality into **onpload**.

The **ipload** utility identifies custom software by the driver name that you assign to the record-format definitions.

To incorporate custom file-handling software directly into the **onpload** program:

1. Use the API described in Available API support functions to write the driver.
2. Add the driver name to the onpload database. For details, see Adding a custom-driver name.
3. Select the driver from the Driver selection list in the Format Options window. For details, see Format options.

- The Drivers window
  You can add information about custom drivers from the Drivers window. After you add a custom driver name, you can assign the driver to the record-format definitions.
- Adding a custom-driver name

The Drivers window

You can add information about custom drivers from the Drivers window. After you add a custom driver name, you can assign the driver to the record-format definitions.

The following figure shows the Drivers window. The Driver Name list box displays the currently available drivers, their class, and type.
Figure 1. The Drivers window

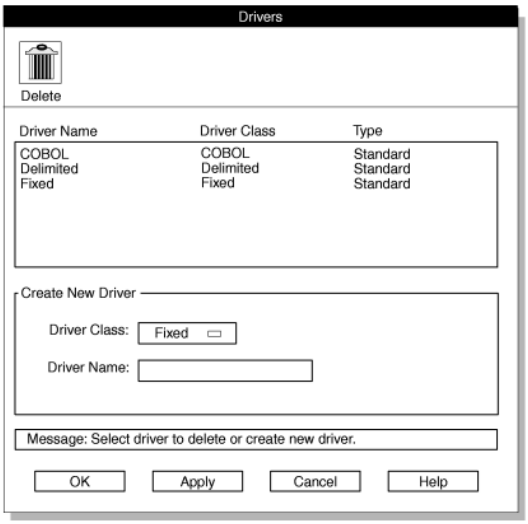


Table 1. The Drivers window options

Display option	Description
Driver Name	The Driver Name text box specifies the name of the custom-driver program. Before you can use the custom driver, you must add the program to your **onpload** shared library. For more information, see Rebuilding the shared-library file.
Driver Class	The Driver Class text box specifies the format type that the custom driver supports. The custom driver must produce data in a format that **onpload** supports. The **onpload** utility supports the following driver classes: • Fixed • Delimited • COBOL

Related reference:
The driver table in the onpload database

Adding a custom-driver name

To add a custom-driver name:

1. Choose Configure > Driver from the HPL main window.
   The Drivers window appears, as Figure 1 shows.
2. Type the name of the driver that you are adding in the Driver Name text box.
3. Select the driver class.
4. Click Apply to save this driver and add another driver.
   If you want to add only one driver, click OK instead of Apply.
5. When you finish, click OK to return to the HPL main window.

Modify the machine description

The information that the Machines option of the Configure menu stores describes the characteristics of a specific computer. The High-Performance Loader (HPL) uses these characteristics to control the conversion of binary data formats. Unless you are converting binary data, you do not need to be concerned about the machine description.

When you first start **ipload**, **ipload** stores the characteristics of several computers. You can select one of the existing computer types, modify an existing description, or create a machine description.

You use the information from the Machines window when you prepare the defaults for the database servers on your network. The information from the Machines window is stored in the **machines** table of the onpload database. The default information for the HPL includes descriptions of the binary data sizes for several computers. If the default data does not include the computer from which you are reading data, you can create a description for that computer.

- The Machines window
- Editing the description of a computer
- Adding a computer type to the Machines list

Editing the description of a computer

To edit the description of a computer:

1. Choose Configure > Machines from the HPL main window.
   The Machines window appears, as Figure 1 shows.
2. Click the down arrow and select a machine type from the selection list.
3. Modify the values as appropriate.
4. Click Apply to save the values and modify another machine description.
5. When you finish, click Cancel to return to the HPL main window.

If you want to modify the description of only one computer, click OK instead of Apply.

Adding a computer type to the Machines list

To add a computer type to the Machines list:

1. Choose Configure > Machines from the HPL main window.
   The Machines window appears, as Figure 1 shows.
2. Type the new name in the Machine Type text box.
3. Type an appropriate value in each text box.
4. Click Apply to save the values and add another computer type.
5. When you finish, click Cancel to return to the HPL main window.

If you want to add only one computer type, click OK instead of Apply.

Define device arrays

This section describes how to define and use device arrays with the High-Performance Loader (HPL).

- Device arrays
  A device array groups several I/O devices so that the High-Performance Loader (HPL) can perform parallel processing of the input and output. When you specify multiple devices in a device array, **onpload** sets up separate, parallel streams of input or output, when it performs a database load or unload.
- Multiple devices in a device array
- The Device-Array Selection window
  You can create a device array or select an existing array from the Device-Array Selection window. If you select an existing array, you can edit that array or use one of the toolbar buttons to copy, delete, or print the array.
- The Device-Array Definition window
  You can add, edit, or delete devices from an array from the Device-Array Definition window.

Related concepts:
Components of the unload job

Device arrays

A device array groups several I/O devices so that the High-Performance Loader (HPL) can perform parallel processing of the input and output. When you specify multiple devices in a device array, **onpload** sets up separate, parallel streams of input or output, when it performs a database load or unload.

Device arrays set up simultaneous access to one or more tape devices, files, or pipes (UNIX only) so that the **onpload** utility can take advantage of parallel processing.

Device arrays are not project specific. You can use the same device array for a load or unload job on any of the projects that you define.

Related reference:
Define device arrays

Multiple devices in a device array

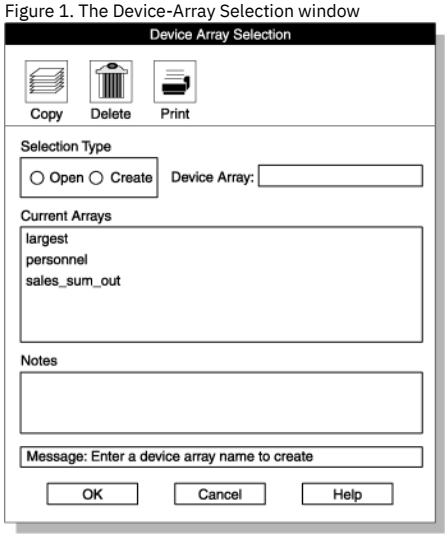
You can include files, pipes (UNIX only), and tape devices in a single array. Devices for the device array discusses factors that you should take into account when you decide what devices to assign to an array. If your array includes pipe commands, **onpload** starts the pipe when it begins execution.

When the High-Performance Loader (HPL) unloads data, it assigns records to the devices of a device array in a round-robin fashion.

The Device-Array Selection window

You can create a device array or select an existing array from the Device-Array Selection window. If you select an existing array, you can edit that array or use one of the toolbar buttons to copy, delete, or print the array.

The following figure shows the Device-Array Selection window.
Figure 1. The Device-Array Selection window



- Creating a device array
- Opening an existing device array

Creating a device array

To create a device array:

1. Choose Components > Devices from the HPL main window.
   The Device-Array Selection window appears, as Figure 1 shows.

2. Click Create in the Selection Type group.
3. Select a name for the new device and type it in the Device Array text box.
4. Click OK.
   The Device-Array Definition window appears, as Figure 1 shows.

Opening an existing device array

To open an existing device array:

1. Choose Components > Devices from the HPL main window.
   The Device-Array Selection window appears, as Figure 1 shows.

2. Click Open in the Selection Type group.
3. Select a device from the Current Arrays list box.
4. Click OK.
   The Device-Array Definition window appears, as Figure 1 shows.

The Device-Array Definition window

You can add, edit, or delete devices from an array from the Device-Array Definition window.

Figure 1. A partially completed Device-Array Definition window

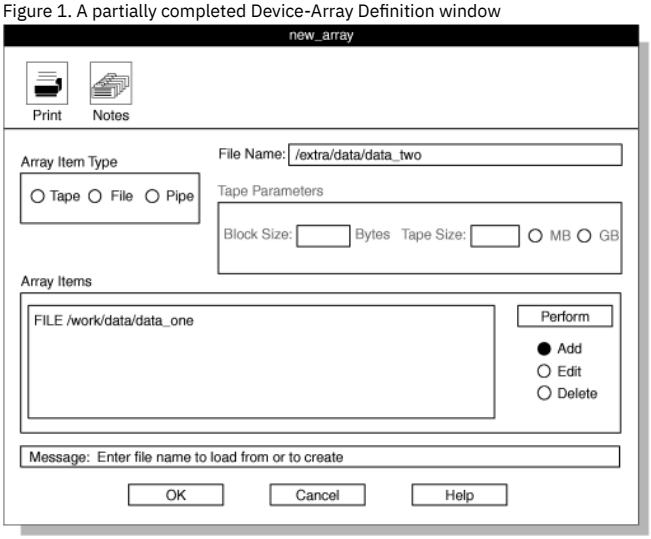


Table 1. The Device-Array Definition window options

Display option	Description
Array Item Type group	The Array Item Type group lists the types of devices that you can include in a device array. You can mix different types of devices in a single array.
Device text box	Depending on the array item type that you selected from the Array Item Type group, the label for the text box where you type a device name is **Tape Device**, **File Name**, or **Pipe Command** (UNIX only). Complete this text box as follows. **Device type** **What to type** Tape Device The full path name of the tape device (example: /dev/rmt/0) File Name The full path name of the file (example: /work/mydata) Pipe Command The full path name of the executable pipe command or shell script (example: /tmp/g)

Display option	Description
Tape Parameters group	When you select Tape as the array item type, the Tape Parameters group becomes active (not gray), as the following figure shows. You must type the block and tape size. The tape size must be greater than zero. The example shown in the following figure is for UNIX. An example of a tape device name for Windows is 11.1tape0. Windows does not support remote tape load and unload. Figure 2. The tape parameters group 
- Adding, editing, and removing devices
  You can add devices to the device array, you can edit the devices, and you can remove them.

Related reference:
The device table in the onpload database

Adding, editing, and removing devices

You can add devices to the device array, you can edit the devices, and you can remove them.

- Adding devices to the device array
- Editing a device in the device array
- Deleting a device from the device array

Adding devices to the device array

To add devices to the device array:

1. Click Add in the Device-Array Definition window.
2. Click the device type in the Array Item Type group.
3. Type the full path name of the device in the Device text box. If you specified a tape device, the Tape Parameters group becomes active, as Figure 2 shows.
   a. Type the block size in kilobytes.
   b. Click MB (megabytes) or GB (gigabytes) to specify the units to use for the tape size.
   c. Specify the tape size.
4. When you have included all of the information for the device, click Perform. The device that you added appears in the Array Items list box.
5. Repeat steps 2 through 4 to add other items to the device array.
6. When you have added all of the devices to the array, click OK to return to the Device-Array Selection window. Your new array appears in the Current Arrays list box.
7. Click Cancel to return to the HPL main window.

Editing a device in the device array

To edit a device in the device array:

1. Click Edit in the Device-Array Definition window.
2. Select a device from the Array Items list box. The selected item appears in the Device text box.
3. Edit the path name and tape parameters, as appropriate.
4. Click Perform.
5. Click OK to return to the Device-Array Selection window.
6. Click Cancel to return to the HPL main window.

Tip: When you edit a device, you can change the path name and the tape parameters, but you cannot change the array-item type (tape, file, pipe). If you need to change the device type, you must delete the item and then add a new item.

Deleting a device from the device array

To delete a device from the device array:

1. Click Delete in the Device-Array Definition window.
2. Select a device from the Array Items list box.
3. Click Perform.
4. Click OK to return to the Device-Array Selection window.

5. Click Cancel to return to the HPL main window.

Define formats

This section describes the formats that the High-Performance Loader (HPL) provides and shows how to prepare and edit the format component.

- Formats
  A format describes the structure of the data in a data file.
- Formats of supported datafile records
- Fixed-length records
- Delimited records
  Delimited records are records whose fields can vary in length. In a data file that contains delimited records, the records and fields are separated by a delimiter.
- COBOL records
- Other formats
  In addition to delimited, fixed, and COBOL formats, the High-Performance Loader (HPL) provides two other formats for loading and unloading data: fast format and fast job. These formats are not included on the Record Formats window because the format specifications are predefined; you do not need to make any choices.
- Format options
  The format options let you change the default driver, the character set, the default computer type, and the delimiters. Information about the format options is stored in the **formats** table of the **onpload** database.
- Format Views window
  You can display a list of the formats and load and unload maps that are associated with a project from the Format Views window. You can also create or edit a format.

Related concepts:
Components of the unload job

Formats

A format describes the structure of the data in a data file.

Before you can import records from a data file into IBM® Informix® databases or export records from a database to a data file, you must define a format that describes the data file. You do not need to define a format for the database because **ipload** already knows the schema (the organization) of the database table.

These topics use the term *format* in two ways:

- To refer to the arrangement of data fields in a record of a data file
- To refer to the HPL component that documents the arrangement of the data fields

After you familiarize yourself with the concepts in this section, you might save yourself some work by using one of the Generate options to create formats automatically.

Related reference:
The Generate options of the ipload utility

Formats of supported datafile records

Data files can be structured in various ways. The High-Performance Loader (HPL) supports data-file records of the following formats:

- Fixed-length
- Delimited
- COBOL
- Other formats

You can define new format components at any time. Also, you can test your format before you actually load or unload data.

The **ipload** utility includes options that let you modify the data before it is inserted into the database.

The **ipload** utility stores information about formats in the **formatitem** and **format** tables of the onpload database.
Important: To prepare the format component, you must know the format of the records in the data file. If you do not know the data-file format, you must get it from the person who provided the data file.

Define formats

Fixed-length records

In fixed-length or fixed-format records, each field starts and ends at the same place in every record. A data file that contains data records of equal and constant length might be organized as follows.
Figure 1. Sample file with fixed-length records

```
aaabbbbcccddddggghhhh
```

The data file illustrated previously has three records. Each record has a field of three characters followed by a field of four characters, so the total record length is seven characters. The file does not contain any separation between records; delimiters are unnecessary because all fields have the same length. The VARCHAR data types are therefore always the fixed maximum size of the field.

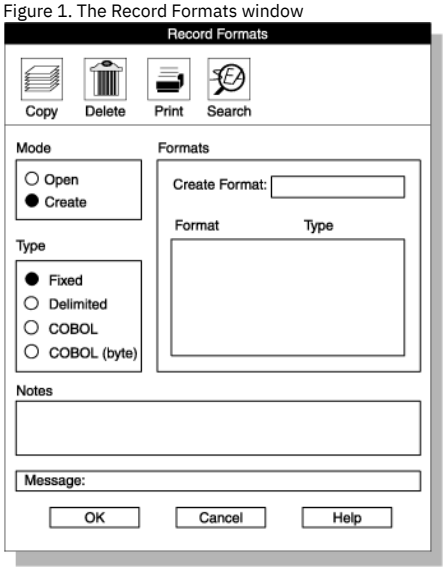
When you define a fixed-length format, you specify the length of each field. The **ipload** utility calculates the offset for each field and the total length of the record from the field lengths that you supply.

- Creating a fixed format
  You can create and define formats for fixed-length records from the Record Formats and the Fixed Format Definition windows.
- Editing a format
  After you create and save a format, you might need to add a new field, insert a new field, edit a field, or delete a field. The process for editing an existing format is essentially the same, regardless of the file type.
- Create a fixed format that uses carriage returns
- Create a fixed format that includes BYTE or TEXT data
  You can organize the byte or text data in a fixed-format data file with inline data or data in a separate file.
- Create a fixed format that includes Ext type or Simple LO data
  You can organize the Ext Type or Simple LO data in a fixed-format data file with fixed-length data or inline data.

Creating a fixed format

You can create and define formats for fixed-length records from the Record Formats and the Fixed Format Definition windows.

To create a format for fixed-length records:

1. Choose Components > Formats from the HPL main window.
   The Record Formats window appears, as the following figure shows.
   Figure 1. The Record Formats window
   


2. Click Create in the Mode group.
3. Click Fixed in the Type group.
4. Choose a name for the format and type it in the Create Format text box.
5. Click OK.
   The Fixed Format definition window appears. The title bar includes the name that you chose for the format. The following figure shows the Fixed Format Definition window as it might appear after you prepare the format for the file that Figure 1 shows.
   Figure 2. A completed Fixed-Format Definition window with an open selection list

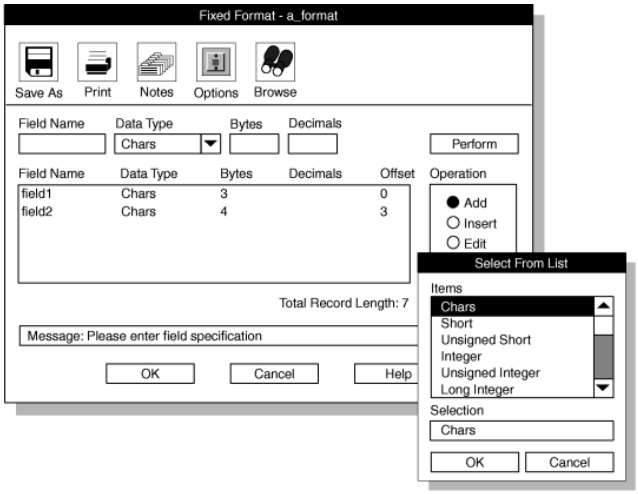


Table 1. The Fixed-Format Definition window options

Display option	Description
Bytes	The Bytes text box specifies the number of characters that the field occupies in the record. In the Bytes text box, you must set the number of bytes for your data types. Although **ipload** uses default information to calculate an offset if you create a format that has a new length, it does not readjust the lengths for existing formats. To change the default information, see The Machines window. The **ipload** utility automatically calculates the total length of the data file as you add each field description.
Decimals	The Decimals text box specifies the number of decimal places that are displayed when you convert floating-point types to ASCII. You can set the number of decimals only for the **Float** and **Double** data types.

6. Click Add in the Operation group.
7. Choose a name for the field and type the name in the Field Name text box.
8. Type the data type in the Data Type text box. For columns that contain user-defined types (UDTs) columns, you must choose an Ext Type format. For information about user-defined types, see *IBM® Informix® Guide to SQL: Reference*.
   The down arrow next to the Data Type text box displays the selection list that appears at the right in Figure 2. Data types allowed in a fixed format describes the data types that appear in the selection list.
9. Type the appropriate value in the Bytes text box (or in the Decimals text box, if appropriate). If you chose the Ext Type String in the Data Type box, you must specify a size, or you get an error. Field size depends on the type of data and its representation in the data file.
10. Click Perform.
    After you click Perform, **ipload** calculates the proper offset for this field in the record and displays the value under the Offset heading, as Figure 2 shows.
11. Repeat steps 7 through 10 for each field in your data file.
12. Click OK to save the format and return to the Record Formats window.
13. Click Cancel to return to the HPL main window.

Tip: Use the field name to map the data file to the database. You can type any name that you choose. You might find it easier to remember the names if you use the same name as the corresponding column of the database.

- Data types allowed in a fixed format

Related reference:
The formats table in the onpload database

Data types allowed in a fixed format

You can use the following data types when you are preparing a fixed format.

Data type	Description
Chars	ASCII format data
Short Unsigned Short Integer Unsigned Integer Long Integer Unsigned Long Float Double	The Machines description specifies the number of bytes required in fixed format for integers and floating-point values (see The Machines window.) When you select one of these data types, **ipload**sets the number of bytes.
Date	Date string
UNIX Date	A long integer interpreted as the system date from a UNIX system
Blob Length	The number of bytes of BYTE and TEXT (binary large object) that follow this record
Blob File	A file that contains BYTE and TEXT data
BLOB and CLOB	A file that contains smart large object (BLOB or CLOB) data
Simple LO Length	The number of bytes of simple large object data (BYTE and TEXT data) that follow this record
Simple LO File	The name of a file that contains a Simple LO data (BYTE and TEXT data)
INT8	An eight-byte integer type
SERIAL8	An eight-byte serial column
BIGINT	An ASCII character string or an eight-byte integer type

Data type	Description
BIGSERIAL	An ASCII character string or an eight-byte integer type
Ext Type String	The ASCII representation of an extended data type (Ext Type) value
Ext Type String Length	The length of an ASCII Ext Type value. The Ext Type value follows at the end of the input/output record. Use Ext Type String Length data type if you have data that contains null UDT values.
Ext Type Binary	The binary representation of an Ext Type value
Ext Type Binary Length	The length of the binary representation of an Ext Type value. The binary value follows at the end of the input/output record. Use Ext Type Binary Length data type if you have data that contains null UDT values.

The HPL supports several data types under the Ext Type mechanism. As a result, the specific names of these data types do not appear in the data-type selection list. For the following data types, choose the appropriate Ext Type data type:

- INT8
- LVARCHAR
- SERIAL8
- BLOB
- BOOLEAN
- CLOB
- Collection data types
- Distinct data type
- Opaque data types
- Row types

Editing a format

After you create and save a format, you might need to add a new field, insert a new field, edit a field, or delete a field. The process for editing an existing format is essentially the same, regardless of the file type.

The following example uses a fixed-format file, but the same procedure applies to COBOL and delimited files also.

- Adding a new field description to the format
- Inserting a new field into the format
- Editing the description of a field
- Deleting a field description from the format

Related concepts:
Preview data-file records
Related tasks:
Editing a format

Adding a new field description to the format

To add a new field description to the format:

1. Open the Fixed Format Definition window. For more information, see Creating a fixed format.
2. Click Add in the Operation group.
3. Type the field specifications in the text boxes at the top of the window.
4. Click Perform to add the new field at the end of the list.
5. Click OK to save your changes and return to the Record Formats window.
6. Click Cancel to return to the HPL main window.

Inserting a new field into the format

To insert a new field into the format:

1. Open the Fixed Format Definition window. For more information, see Creating a fixed format.
2. Click Insert in the Operation group.
3. Select the field before which you want to insert the new field.
4. Type the field specifications in the text boxes at the top of the window.
5. Click Perform to insert the new field before the selected field.
6. Click OK to save your changes and return to the Record Formats window.
7. Click Cancel to return to the HPL main window.

Editing the description of a field

To edit the description of a field:

1. Open the Fixed Format Definition window. For more information, see Creating a fixed format.

2. Click Edit in the Operation group.
3. Select the field from the list of fields.
4. Change the information that you want.
5. Click Perform.
6. Click OK to save your changes and return to the Record Formats window.
7. Click Cancel to return to the HPL main window.

Deleting a field description from the format

To delete a field description from the format:

1. Open the Fixed Format Definition window. For more information, see Creating a fixed format.
2. Click Delete in the Operation group.
3. Select the field that you want to delete.
4. Click Perform to delete the field.
5. Click OK to save your changes and return to the Record Formats window.
6. Click Cancel to return to the HPL main window.

Create a fixed format that uses carriage returns

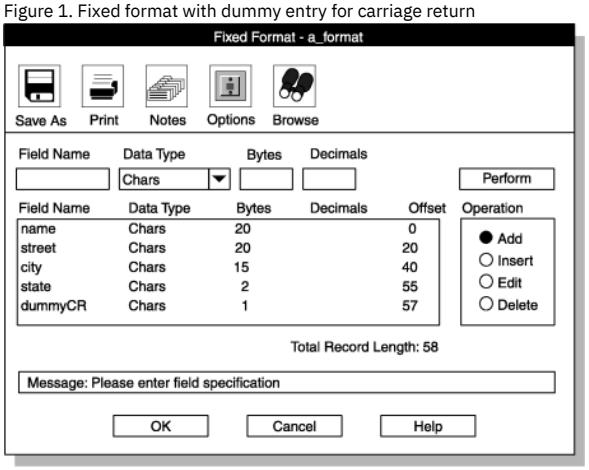
A fixed-format data file often includes a carriage return (new line) at the end of each record, such as the data file in the following example file.

```
20 chars            20 chars            15 chars2         chars

John Brown          100 Main St.        Citadel           LA
Mary Smith          3141Temple          WayChesapeake     AZ
Larry Little        44 Elm Rd. #6       Boston            MA
```

When you prepare the format for this data file, you must include a dummy field for the carriage return. When you create the load map for this format, do not link the dummy field to a database column. The following figure shows the format for the data file illustrated previously.

Figure 1. Fixed format with dummy entry for carriage return



Related tasks:
Creating a load map

Create a fixed format that includes BYTE or TEXT data

You can organize the byte or text data in a fixed-format data file with inline data or data in a separate file.

- Inline data
  BYTE or TEXT data that is included as part of a fixed-format data file is called inline data. When byte or text data is inline, the data-file record has two parts: a fixed-length part and a variable-length part.
- Data in a separate file
  You can also store BYTE and TEXT data in separate files.

Inline data

BYTE or TEXT data that is included as part of a fixed-format data file is called inline data. When byte or text data is inline, the data-file record has two parts: a fixed-length part and a variable-length part.

For example, a record with two fields and byte or text data might be organized as follows.

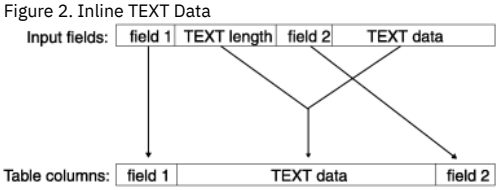
Figure 1. Organization of a record that includes inline TEXT data

```
field1textlengthfield2textdata
```

The length of the TEXT data is included in the fixed-length part of the record. The actual TEXT data is inserted at the end of the fixed-length part of the record. The High-Performance Loader (HPL) reads the TEXT length from the fixed-length part of the record and uses that length to read the actual TEXT data. The HPL also uses the TEXT length to calculate the offset to the beginning of the next record.

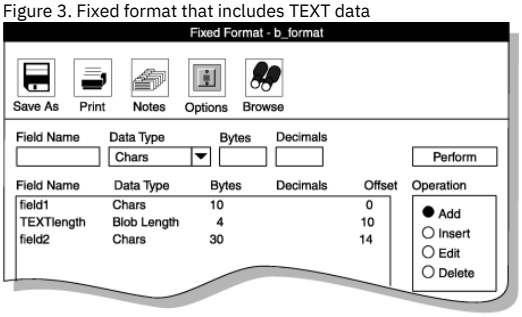
The following figure shows the format definition of a record with inline BYTE and TEXT data. The arrows show how the HPL puts the record into the database. The arrows from **field 1** and **field 2** indicate entries in fixed-length format. The split arrow shows that the HPL uses the **TEXT length** information to find the **TEXT data** and insert it into the table. The HPL does not insert the **TEXT length** into the database.

Figure 2. Inline TEXT Data



When you define the format in the Format-Definition window, select **Blob Length** as the data type for the **textlength** field. The following figure shows the format for the example in Figure 1. The format does not include an entry for TEXT data.

Figure 3. Fixed format that includes TEXT data



When you create a map to link the input fields that are defined by the format to the columns of a database table, connect the **textlength** input field to the table column that contains the TEXT data.

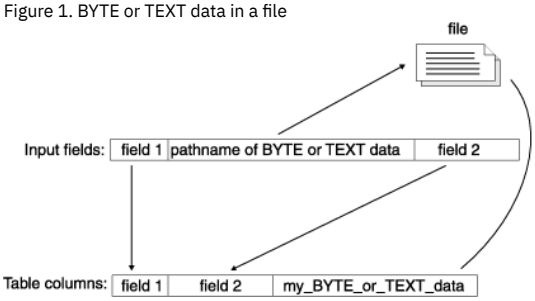
Related reference:
Define maps

Data in a separate file

You can also store BYTE and TEXT data in separate files.

During a load, BYTE and TEXT data files are read and inserted into the database. During an unload job, the file is created, and BYTE and TEXT data is written to the file. When the fixed-format input contains the path name of a data file, the HPL uses that path name to insert data into a column of the database table, as the following figure shows. When you prepare the format, select **Blob File** for the data type.

Figure 1. BYTE or TEXT data in a file



When you create a map to link the fields of the input record to the columns of a database table, link the name of the BYTE or TEXT file with the BYTE or TEXT column. The arrows in Figure 1 illustrate how the HPL inserts the BYTE or TEXT data into the column.

Related reference:
Define maps

Create a fixed format that includes Ext type or Simple LO data

You can organize the Ext Type or Simple LO data in a fixed-format data file with fixed-length data or inline data.

- Fixed-length data
  When you designate a field as an Ext Type String or Ext Type Binary data type, you specify that the data is going occupy a fixed amount of space, similar to the behavior of a fixed-length Chars data type. With fixed-length data format, you must specify the number of bytes that the field occupies in the record.
- Inline data
  Simple LO data or varying-sized Ext Type data that is included as part of a fixed-format data file is called inline data. When Ext Type or Simple LO data is inline, the data-file record has two parts: a fixed-length part and a variable-length part.
- Simple LO data in a separate file
  You can also store Simple LO data in separate files.

Fixed-length data

When you designate a field as an Ext Type String or Ext Type Binary data type, you specify that the data is going occupy a fixed amount of space, similar to the behavior of a fixed-length Chars data type. With fixed-length data format, you must specify the number of bytes that the field occupies in the record.

Inline data

Simple LO data or varying-sized Ext Type data that is included as part of a fixed-format data file is called inline data. When Ext Type or Simple LO data is inline, the data-file record has two parts: a fixed-length part and a variable-length part.

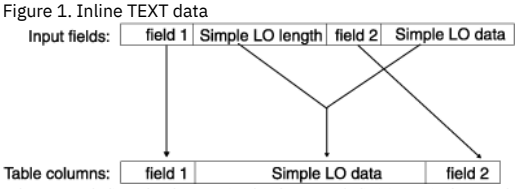
For example, a record with two fields and a Simple LO might be organized as follows.

```
field1Simple LO lengthfield1Simple LO data
```

The data-type length of the Ext Type or Simple LO data is included in the fixed-length part of the record. The actual TEXT data is inserted at the end of the fixed-length part of the record. The HPL reads the Ext Type or Simple LO length from the fixed-length part of the record and uses that length to read the actual Ext Type or Simple LO data. The HPL also uses the Ext Type or Simple LO length to calculate the offset to the beginning of the next record.

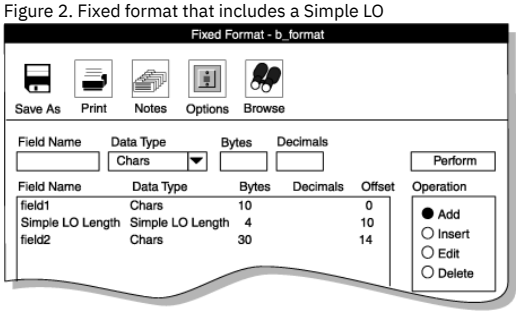
The following figure shows the format definition of a record with inline Ext Type or Simple LO data. The arrows show how the HPL puts the record into the database. The arrows from **field 1** and **field 2** indicate entries in fixed-length format. The split arrow shows that the HPL uses the **Simple LO length** information to find the Simple LO data and insert it into the table. The HPL does not insert the Simple LO length into the database.

Figure 1. Inline TEXT data



When you define the format in the format-definition window, select the appropriate data-type length data type (**Ext Type String Length**, **Ext Type Binary Length**, or **Simple LO Length**) for the data-type length field. The following figure shows the format for the example previously illustrated. The format does not include an entry for Simple LO data.

Figure 2. Fixed format that includes a Simple LO



Important: Ext Type binary-length format is not supported for complex types.

When you create a map to link the input fields that are defined by the format to the columns of a database table, connect the data type length input field to the table column that contains that particular data. In this case, connect the **Simple LO length** input field to the table column that contains the Simple LO data.

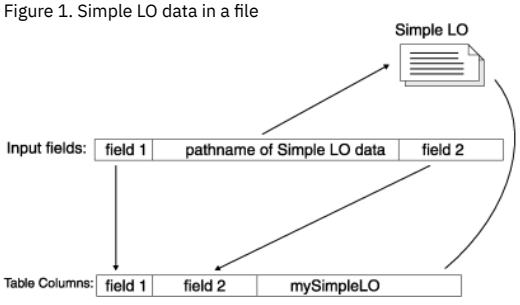
Related reference:
Define maps

Simple LO data in a separate file

You can also store Simple LO data in separate files.

During a load, Simple LO data files are read and inserted into the database. During an unload job, the file is created and BYTE and TEXT data is written to the file. When the fixed-format input contains the path name of a data file, the High-Performance Loader (HPL) uses that path name to insert data into a column of the database table, as the following figure shows. When you prepare the format, select **Blob File** for the data type.

Figure 1. Simple LO data in a file



When you create a map to link the fields of the input record to the columns of a database table, link the name of the Simple LO file with the Simple LO column. The arrows in Figure 1 illustrate how the HPL inserts the Simple LO data into the column.

Related reference:
Define maps

Delimited records

Delimited records are records whose fields can vary in length. In a data file that contains delimited records, the records and fields are separated by a delimiter.

The following data file uses a vertical bar (|) as the field delimiter and a carriage return as the record delimiter:

```
John Brown|100 Main St.|Citadel|LA|215/887-1931
Mary Smith|3141 Temple Way|Chesapeake|AZ|415/812-9919
Larry Little|44 Elm Rd. # 6|Boston|MA|617/184-1231
```

The **ipload** utility uses the vertical bar and carriage return as the default field and record delimiters.

- Create a delimited format
- Create a delimited format that includes BYTE or TEXT data
  In a delimited format, BYTE or TEXT data can be characters, hexadecimal data, or a separate file.
- Create a delimited format with extended data types

Related tasks:
Modifying delimited-format options

Create a delimited format

To create a format for delimited records, follow the same steps as in Creating a fixed format, with the following modifications:

- In step 3, click Delimited in the Type group.
- Omit step 9. When you use delimited records, **ipload** does not need byte or decimal information.

- Data types allowed in a delimited format

Data types allowed in a delimited format

You can use the following data types when you prepare a delimited format.

Table 1. Data types allowed in delimited format

Data type	Description
Chars	Normal ASCII data
BYTE or TEXT File	File that contains BYTE or TEXT data
TEXT Data	TEXT data is formatted as ASCII text. If the text includes carriage returns (new lines) or delimiters, a backslash (\) must precede those characters.
BYTE or TEXT HexASCII	BYTE or TEXT data that is formatted in ASCII hexadecimal. The **onpload** utility translates the data into binary format before it loads the data into the database.
BLOB or CLOB	File that contains smart large object (BLOB or CLOB) data
Simple LO File	The name of a file that contains Simple LO data (BYTE and TEXT data)
Simple LO Text	Simple LO data that is formatted as ASCII text. If the text includes carriage returns, newline characters, or delimiters, a backslash (\) must precede those characters
Simple LO HexASCII	Simple LO data that is formatted in ASCII hexadecimal. The **onpload** utility translates the data into binary format before it loads the data into the database.
Ext Type String	The ASCII representation of a Data Type (Ext Type) value
Ext Type HexASCII	The HexASCII representation of an Ext Type value

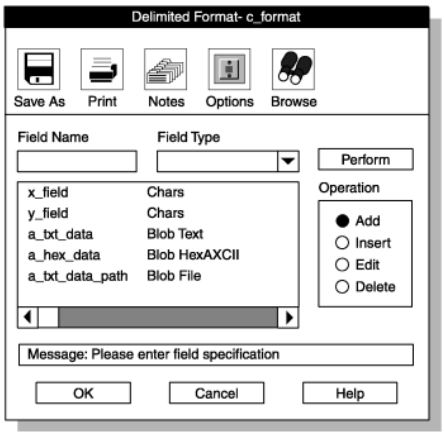
Create a delimited format that includes BYTE or TEXT data

In a delimited format, BYTE or TEXT data can be characters, hexadecimal data, or a separate file.

The following sample data-file record shows a data record that has two fields of character data followed by a field of character BYTE or TEXT data, a field of hexadecimal byte or text data, and the path name of a file that contains BYTE or TEXT data.

```
field1|field2|TEXT data|BEEEF6699|/bbs/kaths/data2jn95
```

The following figure shows a format for the sample data-file record previously illustrated.
Figure 1. Delimited format with BYTE or TEXT entries



Create a delimited format with extended data types

Extended data types include the following data types:

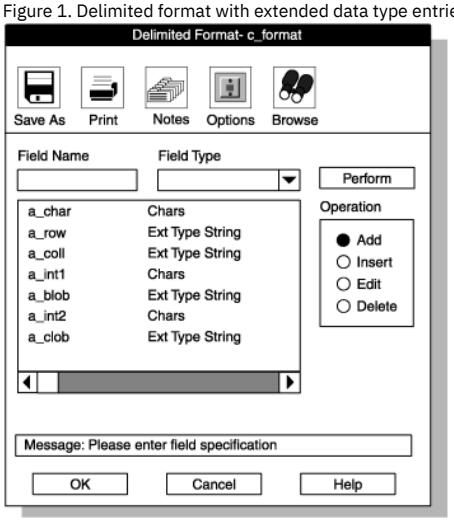
- User defined (distinct and opaque)
- Collection
- CLOB and BLOB
- Row

In a delimited format, CLOB and BLOB data is always written to a file. CLOB data can be ASCII or hexadecimal data. BLOB data can be binary data. The path name of the file, the file size, and the offset are embedded in the data file during unload. However, when you perform a load, you only need to specify the path name.

The following sample data-file record shows a data record that has a field of character data (field1), a row-type field (ROW('abcd', NULL)), a collection-type field (SET{1}), an integer field (10), a BLOB-type field (/work/data/photo.jpg), an integer field (20), and a CLOB-type field (work/data/text.txt).

```
field1|ROW('abcd', NULL|SET{1}|10|/work/photo.jpg|20|
/work/text.txt
```

The following figure shows a sample format for the sample data-file record that was previously illustrated.
Figure 1. Delimited format with extended data type entries



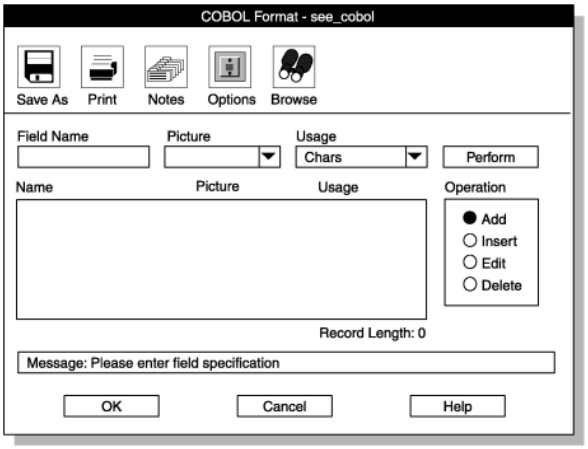
If you unload by using a format that is similar to Figure 1, the unloaded data might resemble the following sample data-file record. You can use this data to load the same file again, instead of using the path name.
Figure 2. Sample data-file record that includes extended data types

```
field1|ROW('abcd', NULL|SET{1 }|10|0,51f4,blob67e9.8ac|20|
0,c 692,clob67e9.9ad
```

By default, the clob67e9.8ad and blob67e9.8ac files in Figure 2 are written to /tmp. To change the default, modify the path in the PLOAD_LO_PATH environment variable.

COBOL records

The HPL supports COBOL sequential data files that do not contain internal indexing. The following figure shows the COBOL-Format Definition window for preparing a COBOL format.
Figure 1. Fixed-format definition window for a COBOL format



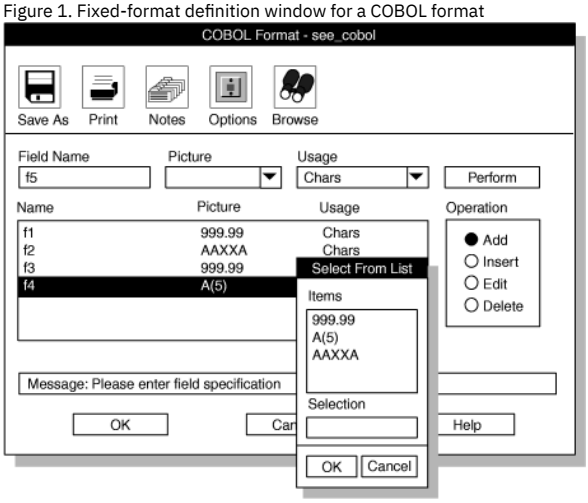
- Create a COBOL format
- Picture and usage descriptions
  The picture and usage description must conform to ANSI-COBOL 85 specifications.

Create a COBOL format

To create a format for COBOL records, follow the same steps as in Creating a fixed format, with the following modifications:

- In step 3, click COBOL in the Type group in the Record Formats window.
- In step 8, type the COBOL picture description in the Picture text box.
- In step 9, type the data type in the Usage text box.
- The arrow displays the selection list of available data types for the Usage text box.

Figure 1. Fixed-format definition window for a COBOL format



Important: Ext types are not supported in COBOL format.

Picture and usage descriptions

The picture and usage description must conform to ANSI-COBOL 85 specifications.

For information about COBOL picture strings, see the documentation for the COBOL compiler.

Picture description

The picture description must match the record file descriptor (FD) from the COBOL program that generates or use the data. For information about COBOL formats, see your COBOL programmer's publication.

Usage description

The usage description must match the data-field type described in the FD descriptor of the COBOL program. If the COBOL program does not include a usage clause, select the Chars (character) option for the usage.

Packed-decimal conversions

When values are converted to packed-decimal formats, supply a picture clause that matches the picture clauses in the COBOL programs that use the data. Otherwise, the COBOL interpretation of the values is wrong.

The following table lists some examples of appropriate picture clauses.

Picture	Input data	Output data	COBOL value =
9999999	123	0000123C	123
9999V99	123	0000123C	1.23
9999.99	123	0000123C	1.23
9999V99	-123.22	0012322D	-123.22

Other formats

In addition to delimited, fixed, and COBOL formats, the High-Performance Loader (HPL) provides two other formats for loading and unloading data: fast format and fast job. These formats are not included on the Record Formats window because the format specifications are predefined; you do not need to make any choices.

Fast format and fast job are the most efficient ways to load and unload data because their formats are predefined.

Fast format

Fast format loads or unloads data in which each individual column uses IBM® Informix® internal format. You can reorder, add, or delete columns, but you cannot conduct conversion on the column itself.

Select Fixed internal in the Generate window to get this type of load. For information about the Generate window, see The Generate options of the ipload utility.

Fast job

A fast job loads or unloads an entire row of the IBM Informix database table in internal format. A fast job is also called a raw load or a no conversion job. For more information, see Format type group.

The **-fn** flag of the **onpload** command-line utility specifies a fast job. For information about the **onpload** utility, see The onpload utility.

Format options

The format options let you change the default driver, the character set, the default computer type, and the delimiters. Information about the format options is stored in the **formats** table of the **onpload** database.

- Modifying fixed and COBOL formats
- Modifying delimited-format options

Related concepts:
Formats of supported datafile records
Related reference:
The formats table in the onpload database
Format type group

Modifying fixed and COBOL formats

You can modify the following options for fixed and COBOL formats.

Character set
: The code set that is used to translate the data in the data table

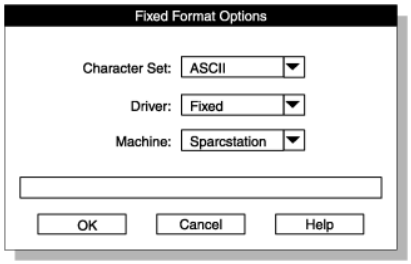
Driver
: The driver that is used with the delimited format. For more information, see Selecting a driver.

Machine
: The machine type that produced the data files. For more information, see Modify the machine description.

For a fixed format, you can select the GLS code set you want from the Character Set selection list. For information about locales and code sets, see the *IBM® Informix® GLS User's Guide*.

To modify the options for fixed and COBOL formats:

1. Display the Format-Definition window for the format that you want.
   To display the window, follow the steps in Creating a fixed format.
2. Click Options.
   The Options window (in this example, the Fixed Format Options window) appears, as following figure shows.
   Figure 1. The Fixed Format Options window



3. Modify the options as appropriate.
4. Click OK to save your options and return to the Format-Definition window.

Modifying delimited-format options

You can modify the following options of the delimited format from the Delimiter Options window.

Character set
: The code set used to translate the data in the data table.

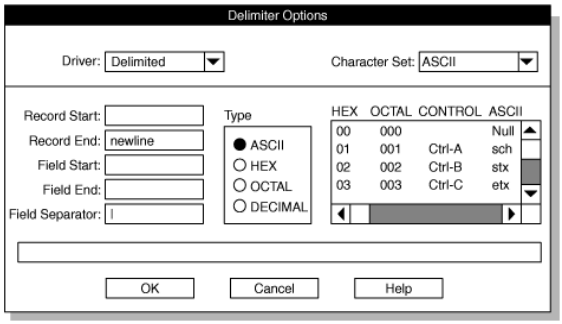
Driver
: The driver that is used with the delimited format. For more information, see Selecting a driver.

Delimiting characters
: The delimiting characters, which are sometimes called record separators and field separators, indicate the beginning and end of records and fields. You can specify the delimiting characters in ASCII, HEX, OCTAL, or DECIMAL format.

You can select the GLS code set you want from the Character Set selection list. For information about locales and code sets, see the *IBM Informix GLS User's Guide*.

To modify the options for delimited formats:

1. Display the Delimited Format Definition window.
   To display the window, complete the steps in Creating a fixed format with the following modification: in step 3, click Delimited.
2. Click the Options button in the Delimited Format Definition window.
   The Delimiter Options window appears, as the following figure shows.
   Figure 1. The Delimiter Options window



3. Modify the options that you want to change, or add information.
   For example, add Field Start and Field End information to mark the beginning and end of a field (column).

   The default escape character is **** (the backslash).

   If the **Field Start** and **Field End** values contain both single or double quotation marks and specified characters are not present in a field, an error occurs. The error occurs because the input does not match the expected layout. If one of these characters appears in a field, you must mark the character with the escape key (to escape the character).

   For comma-separated values (CSV), enter , (a comma) in the Field Separator field. For more information, see Testing the import of a CSV file.

   An error can also occur if the **Field Separator** value appears inside a quoted field or any special character (such as the end field, end record, or escape character) appears in a field. In this case, you must also escape the character.

4. Click OK to save your changes and return to the Delimited Format Definition window.

Tip: You can use the DBDELIMITER environment variable to set the field delimiter for the **dbexport** utility and the LOAD and UNLOAD statements. However, do not use DBDELIMITER with the HPL because the **onpload** utility does not use this environment variable.
For more information about environment variables, see the *IBM Informix Guide to SQL: Reference*.

- Testing the import of a CSV file
  This procedure shows how to test importing sample data from a spreadsheet into IBM Informix.

The delimiters table in the onpload database

Testing the import of a CSV file

This procedure shows how to test importing sample data from a spreadsheet into IBM® Informix®.

Files containing comma-separated values (CSV) are a commonly used for transferring simple text data between programs. The CSV format uses a comma as a field separator and a new line as a record separator. Double quotation marks are used to embed commas, new lines, or double quotation marks within strings. Some applications (for example, some spreadsheet applications) provide the option of exporting text data in the CSV format.

To test importing a CSV file:

1. Create a test database and simple table in .
2. In your spreadsheet application:
   a. Create a spreadsheet with columns that correspond to the columns in your table.
   b. Populate the columns with some test data.
   c. Export the data by saving it in .csv format.
3. Copy the resulting .csv file and paste it in a location that you can access from **ipload**.
4. Start **ipload** and choose Components > Generate Job to create a job.
5. In the Generate Job window:
   a. Select Load/Unload Job in the Generate group.
   b. Select Delimited in the Format Type group.
   c. Specify the .csv file as the source for input to the new job you are creating. Specify a name in the Generate Name field, select your database in the Database field, select you table in the Table field, and then insert the full path to the .csv file in the Device field.
   d. Click OK.
6. Load the job by choosing Jobs > Load.
7. While you can do many things (such as filtering and mapping) on the Load Job window, for this test, select the Format button.
   The Delimited Format window appears. You use this window to define the format of the input file.
8. In the Delimited Format window, click the Options button to display the Delimited Options window.
9. In the Delimiter Options window, change the value in the Field Separator field to , (a comma) and click OK.
   The **ipload** utility returns you to the Delimited Format window.
10. In the Delimited Format window, click OK.
    The **ipload** utility returns you to the Load Job window.
11. Click Run to run the job.
    The **ipload** utility displays status information while the job runs, and then it displays the results of the job.
12. Click OK twice to return to the main **ipload** window.

As an evaluation, you can use DBAccess to verify that the data was successfully loaded.

For more information, see Generating load and unload components.

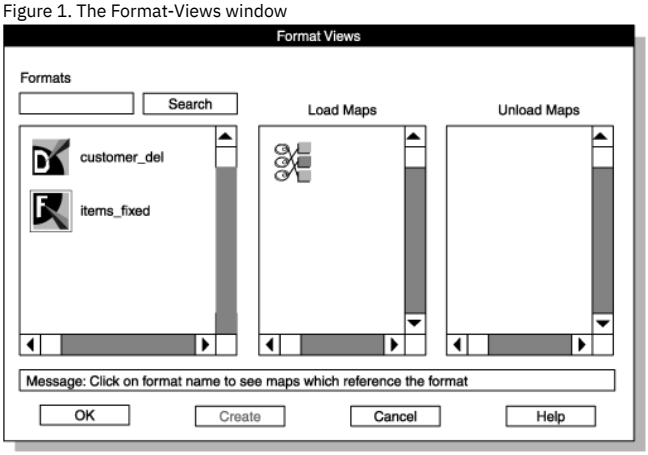
Format Views window

You can display a list of the formats and load and unload maps that are associated with a project from the Format Views window. You can also create or edit a format.

The Format Views window appears in the following situations:

- When you click Format in the Unload Job window and no format name is in the Formats text box
- When you click Search in the Query window

The following figure shows a Format Views window. Views windows discusses how to use Views windows.
Figure 1. The Format-Views window



Define queries

This section describe how to define queries including how to create, edit, and export and import queries.

- HPL queries
  You can build an SQL statement with the **ipload** query component.
- Creating a query
  Use the Query window to create a query.
- Editing a query
  To edit a query, follow the same steps as for creating a query, but open an existing query in the Query window.
- Exporting and importing queries
  You can use the File button on the Query-Definition window to export a query to a file or to import a query that you prepared with some other tool.
- The Database Views window
  You can display a list of the queries, maps, and formats that are associated with a project from the Database Views window. You can also create or edit a query.

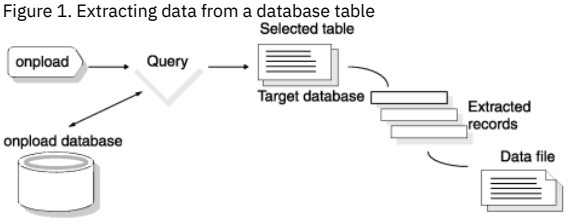
Related concepts:
Components of the unload job

HPL queries

You can build an SQL statement with the **ipload** query component.

The **ipload** utility stores query information in the **query** table of the onpload database. The SQL statement is stored as TEXT data.

During the unload process, the High-Performance Loader (HPL) uses a query to select data from a database table (or tables), as the following figure shows. The HPL can process any valid SQL statement.
Figure 1. Extracting data from a database table



These topics use the term *query* in two ways:

- To refer to the SQL statement that selects information from the database
- To refer to the HPL component that lets you build and store the SQL statement

Related reference:
The query table in the onpload database

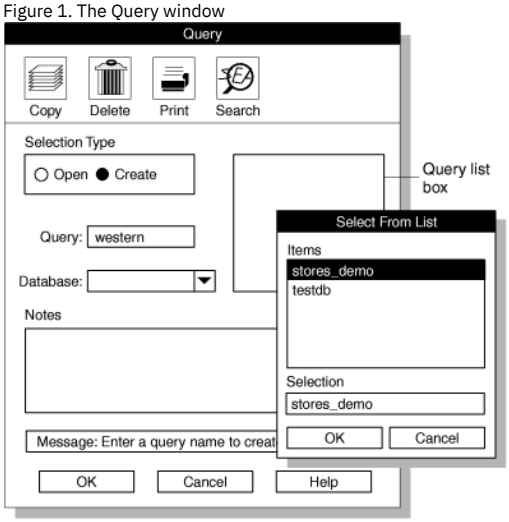
Creating a query

Use the Query window to create a query.

To create a query:

1. Choose Components > Query from the HPL main window.
   The Query window appears, as Figure 1 shows.

2. Click Create in the Selection Type group.
3. Choose a name for your query and type it in the Query text box.
4. In the Database text box, type the name of the database that contains the tables from which you want to extract data. Or, click the down arrow to select from a database selection list.
   The following figure shows the Query window with the Query text box completed and **stores_demo** selected from the selection list.
   Figure 1. The Query window



5. Click OK.
   The Query-Definition window appears, as Figure 2 shows. The name that you chose for your query appears in the title bar.

6. Type your query in the Select, From, and Where text boxes.
   The following figure shows the following simple query of the **customer** table of the **stores_demo** database:

```
SELECT customer.fname, customer.lname,
customer.zipcode
FROM customer
WHERE zipcode > 50000
```

   Figure 2. The Query-Definition window

   If you prefer, you can type the entire query into the Select text box. If you later edit the query, **ipload** divides the query into SELECT, FROM, and WHERE clauses.

7. Click OK to save the query and return to the Query window.
   The query that you just created now appears in the Query list box at the right side of the Query window.

8. Click Cancel to return to the HPL main window.

- Using the Column Selection window
  The Table button displays the Column Selection window. You can use the Column Selection window to build queries by selecting tables and columns. The **ipload** utility inserts the selected columns and tables into the appropriate text boxes of the Query-Definition window.
- Editing the WHERE clause
  When you use the Column Selection window to select a column or columns for the WHERE clause, the selected columns appear in the Where text box.

Related reference:
The query table in the onpload database

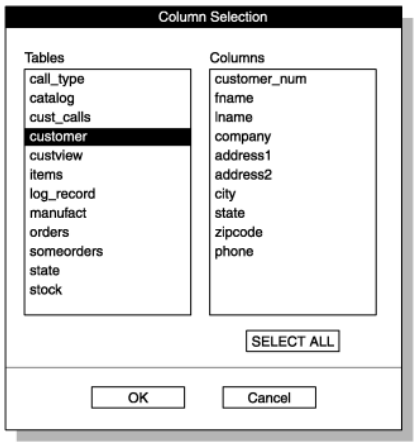
Using the Column Selection window

The Table button displays the Column Selection window. You can use the Column Selection window to build queries by selecting tables and columns. The **ipload** utility inserts the selected columns and tables into the appropriate text boxes of the Query-Definition window.

To use the Column Selection window:

1. Follow the steps in Creating a query to display the Query-Definition window.
2. Click Table.
   The Column Selection window appears, as Figure 1 shows. The Tables list box includes synonyms and views that are valid for the local database server.

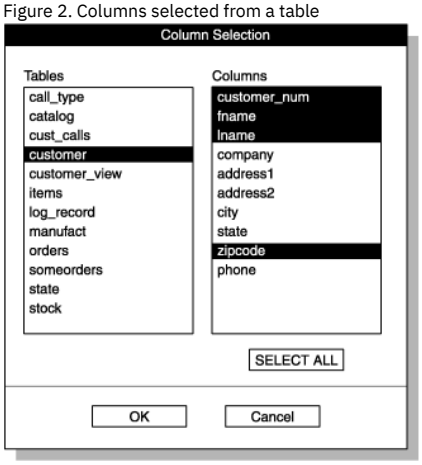
3. Select a table.
   After you select a table, the right pane displays a list of the columns in that table. The following query shows the Column Selection window with the **customer** table selected.
   Figure 1. The Column Selection window after selecting a table



4. Select one or more columns to use in the query.
   - To select a single column, select that column.
   - To select all columns, click Select All.
   - To select consecutive columns, select the first column. Move to the final column and hold down SHIFT while you select that column.
   - To select nonconsecutive columns, select a column. Hold down CONTROL while you select additional items.

   The following figure shows the Column Selection window with several columns selected.

   Figure 2. Columns selected from a table

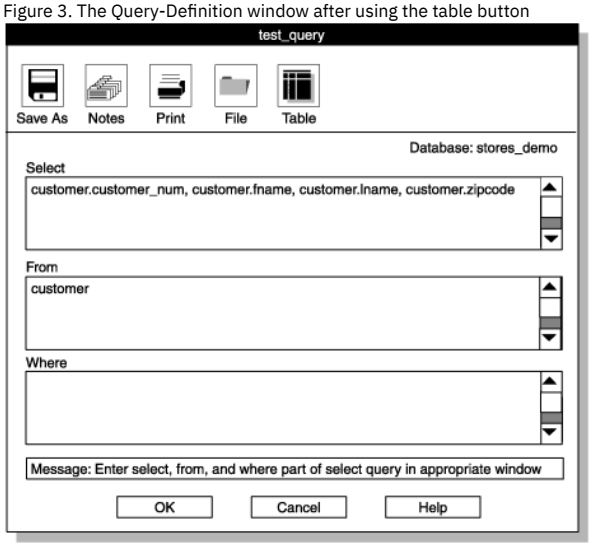


5. When you finish selecting columns, click OK to return to the Query-Definition window.
   When the Query-Definition window reappears, the mouse cursor changes to a pointing hand and the message line reads:

   ```
   Position Cursor Where Column Data to be Inserted
   ```

6. Select the Select text box or the Where text box.
   The following figure shows columns inserted into the Select text box. The **ipload** utility also inserts the table name into the From text box.

   Figure 3. The Query-Definition window after using the table button



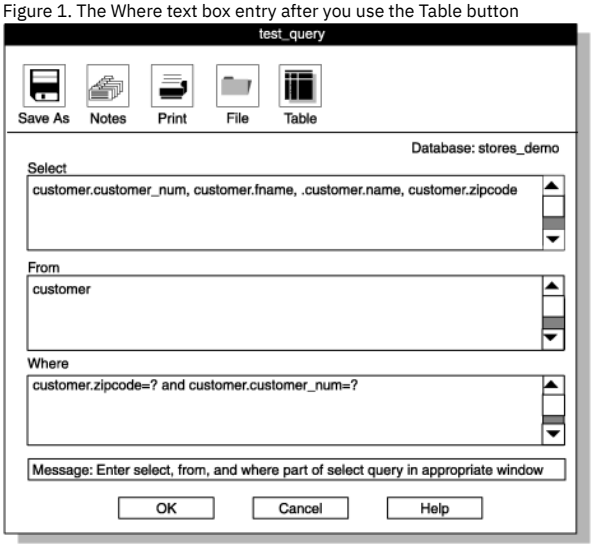
7. Repeat steps 2 through 6 to add columns from other tables.
8. Modify the text in the Where text box so that it is a valid WHERE clause. See Editing the WHERE clause.
9. Click OK to save the query and return to the Query window.
10. Click Cancel to return to the HPL window.

Editing the WHERE clause

When you use the Column Selection window to select a column or columns for the WHERE clause, the selected columns appear in the Where text box.

In the Where text box, as shown in the figure below, the `=?` symbols indicate where you must provide match conditions. The following figure shows the result when you choose **zipcode** and **customer_num** from the **customer** table.

Figure 1. The Where text box entry after you use the Table button



To edit the WHERE clause:

1. Select `=?` and change it to the match condition that you want.
   For example, the Where text box in Figure 1 contains the following text:

   ```
   customer.zipcode =? and customer.customer_num =?
   ```

   You must change both occurrences of `=?` to valid match conditions. You might change the text as follows:

   ```
   customer.zipcode > 50000 and
   customer.customer_num > 150
   ```

   For a full description of match conditions, see Match condition operators and characters.

2. Check the comparison operators.
   When you select multiple columns from the Column Selection window, **ipload** inserts `and` into the expression between each column. You might need to change `and` to `or`.

Editing a query

To edit a query, follow the same steps as for creating a query, but open an existing query in the Query window.

To edit a query:

1. Choose Components > Query from the HPL main window.
   The Query window appears, as Figure 1 shows.

2. Click **Open**.
3. Select a query from the list of queries.
4. Click OK.
   The Query-Definition window appears, as Figure 2 shows. The name of the query that you are editing appears in the title bar.

5. Modify the Select, From, and Where text boxes.
6. Click OK to save the modified query.
7. Click Cancel to return to the HPL main window.

Exporting and importing queries

You can use the File button on the Query-Definition window to export a query to a file or to import a query that you prepared with some other tool.

For example, you might use DB-Acess to prepare and test a query and to save the query to a file. You can then import that query into the High-Performance Loader (HPL).

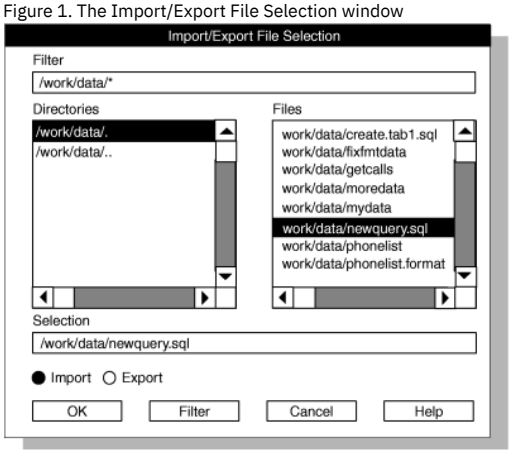
- Importing a query
  You can use the Import/Export File Selection window to import a query that you prepared outside of the High-Performance Loader (HPL).
- Exporting a query
  The File button also allows you to export the query as an SQL statement.

Importing a query

You can use the Import/Export File Selection window to import a query that you prepared outside of the High-Performance Loader (HPL).

To import a query:

1. Display the Query-Definition window by following the steps in Creating a query.
2. Click File.
   The Import/Export File Selection window appears, as the following figure shows.
   Figure 1. The Import/Export File Selection window



3. Click Import.
4. Specify the file that you want to import.
   a. Type a path name and appropriate wildcards in the Filter text box and click Filter. Use an asterisk (*) to list all of the files in the directory. Then select a file and click OK or double-click a file name.
   b. Type the full path name in the Selection text box and then click OK.

   The text from the imported file appears in the Query-Definition window.

   If **ipload** can interpret the SQL statement, the SQL statement is inserted into the appropriate Select, From, and Where text boxes.

   If **ipload** cannot interpret the SQL statement, the entire content of the imported file appears in the Select text box.
5. Edit the query so that it meets your needs.
6. Click OK.
   If the query is a valid SQL query, the display returns to the Query window.

   If the query is not a valid SQL query, **ipload** highlights the portion of the query that it cannot interpret and provides an error message.
7. From the Query window, click Cancel to return to the HPL main window.

Exporting a query

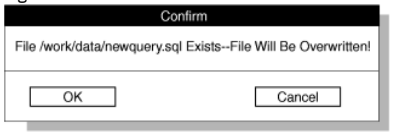
The File button also allows you to export the query as an SQL statement.

You can prepare a query for export in the following ways:

- Create a query. (See Creating a query.)
- Open an existing query.
- Import an already prepared query and modify it. (See Importing a query.)

To export a file:

1. Follow the steps in Creating a query to prepare a query in the Query-Definition window (see Figure 2).
2. Click File.
   The Import/Export File Selection window appears (see Figure 1).
3. Click Export.
4. Select the directory and file where the query is to be stored.
   a. Add the name of a new file to a path name in the Selection text box and click OK.
   b. Type a path name and appropriate wildcard in the Filter text box and click Filter. Then select a file name.
5. Click OK.
   If the file that you specified exists, **ipload** asks if you want to overwrite the existing file, as the following figure shows.
   Figure 1. The Confirm File Overwrite window



6. You now have two choices:
   - Click OK to overwrite. The display returns to the Query window.

- Click Cancel to choose a different file name.

The **ipload** utility writes the text from the Select, From, and Where text boxes into the specified file as a single SQL statement.

7. Click OK. The display returns to the Query window.

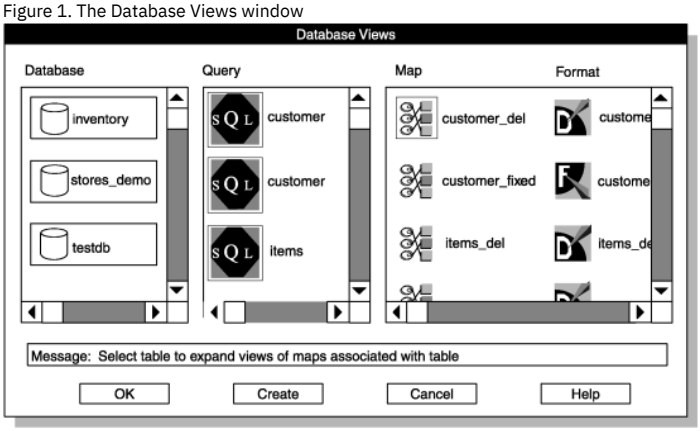
The Database Views window

You can display a list of the queries, maps, and formats that are associated with a project from the Database Views window. You can also create or edit a query.

The Database Views window appears in the following situations:

- When you click Query in the Unload Job window and no query name is in the Query text box
- When you click Search in the Query window

The following figure shows the Database Views window. Views windows discusses how to use Views windows.
Figure 1. The Database Views window



Define maps

This section describes how to define maps with the High-Performance Loader (HPL). It also describes the options that are available for defining maps.

- Load and unload maps
  You can use the **ipload** utility to build a *map*. A map specifies the relationship between the fields of a data file and the columns of a database.
- Unload maps
  An unload map associates columns extracted from a database by a query with the fields in a data-file record. You can create an unload map from the Load Job window or from the Components menu of the HPL main window. After you define an unload map, you use it with the Unload Job window or the **onpload** utility.
- Mapping options
  The mapping options define conversions that **onpload** applies to the data before it inserts the data into the database (for a load job) or into the data file (for an unload job). These conversions can include case conversion, text justification, data masking through picture strings, default values, and fill characters. The mapping options also allow you to replace imported data with data from other database tables.
- Editing options
  This section discusses specialized options in the Map-Definition window.
- Map Views window
  You can display a list of the components that are associated with a database in a specific project from the Map Views window. You can also create or edit a map.

Inline data

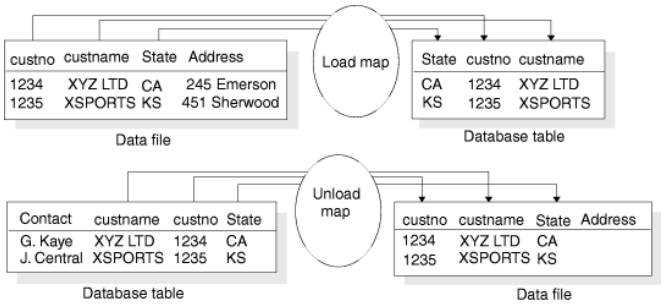
Load and unload maps

You can use the **ipload** utility to build a *map*. A map specifies the relationship between the fields of a data file and the columns of a database.

To load data into a database, you define a load map, which associates fields from records in a data file to columns in a database table.

To unload data, you define an unload map. The unload map associates the columns that a query retrieves from one or more tables to the fields in a data file.

The following figure shows the relationship between load and unload maps.
Figure 1. Using a map



The **ipload** utility stores information about maps in the **maps**, **mapitem**, **mapoption**, and **mapreplace** tables of the **onpload** database.

You can define a map at any time. After you define a map, you use it with the Load Job window or the **onpload** utility.

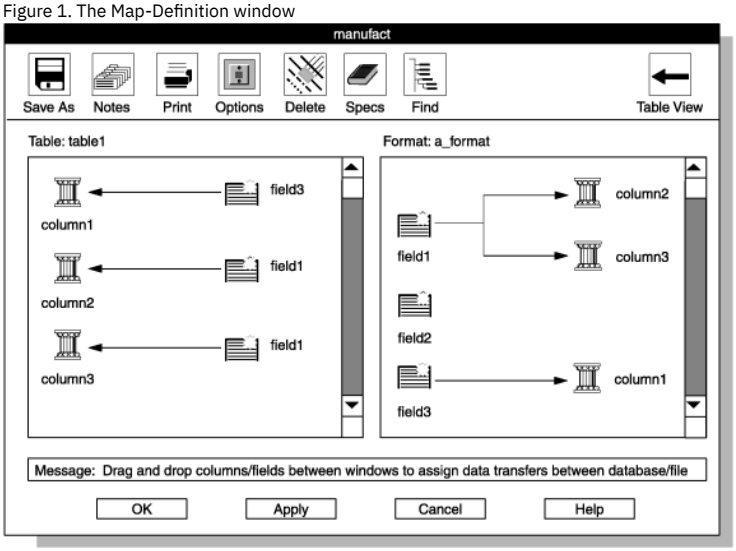
- The Map-Definition window
  You can associate an input item with a table column from the Map-Definition window.
- Creating a load map
  You can create a load map from the Load Job window or from the Components menu of the High-Performance Loader (HPL) main window.

Related reference:
The onpload database
Define maps
The mapitem table in the onpload database
The maps table in the onpload database

The Map-Definition window

You can associate an input item with a table column from the Map-Definition window.

The following figure shows a Map-Definition window for a load map.
Figure 1. The Map-Definition window



The map specifies which fields of the data file are loaded into database columns. The data moves from the fields of a data file into the columns of a database.

- The Table and Format panes
  The Map-Definition window contains two panes: the Table pane and the Format pane.
- Unassigned or multiple-assigned fields and columns
- Identical field names and column names
  When you create a format, you can assign arbitrary names to the fields of the data file. You might find it convenient to assign names that correspond to the names of the columns in the database. When you create a map, **ipload** automatically links columns and fields that have the same name and type, thus saving you work.

The Table and Format panes

The Map-Definition window contains two panes: the Table pane and the Format pane.

The window has two panes so that you can take the following actions:

- Scroll the panes to see all of the columns or fields of a long data file or database table.
- Connect an input field to more than one column.

The left column of icons in each pane represents the active elements of the display. These left columns do not change. In a load map, the columns in the Table pane receive the input. In the Format pane, data from the fields moves into the columns of the database table.

The right column of icons in each pane represents the associations that you make. These columns change as you build the map. A field might be listed more than once in the right column of the Table pane because you can store a field from the data file in more than one database column. This field is mapped (with a split arrow) to two columns in the Format pane. A column never appears more than once in the list to the right of the Format pane because a column can only receive input from one database field.

By scanning the left pane, you can easily see which columns are receiving data from the data file. By scanning the right pane, you can see which fields of the data file are providing data and which fields are not being used.

Unassigned or multiple-assigned fields and columns

The High-Performance Loader (HPL) does not require a one-to-one connection between the fields and columns. You can map a field to multiple columns. Figure 2 shows a map where the data from one field is placed into two columns.

You can also have a column that has no mapping association. Field 1 in the Format pane in Figure 2 does not have an association. If a column does not receive input, **onpload** sets the column to null.

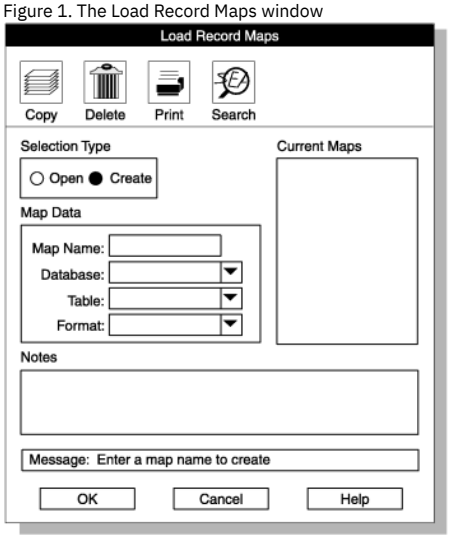
Identical field names and column names

When you create a format, you can assign arbitrary names to the fields of the data file. You might find it convenient to assign names that correspond to the names of the columns in the database. When you create a map, **ipload** automatically links columns and fields that have the same name and type, thus saving you work.

Creating a load map

You can create a load map from the Load Job window or from the Components menu of the High-Performance Loader (HPL) main window.

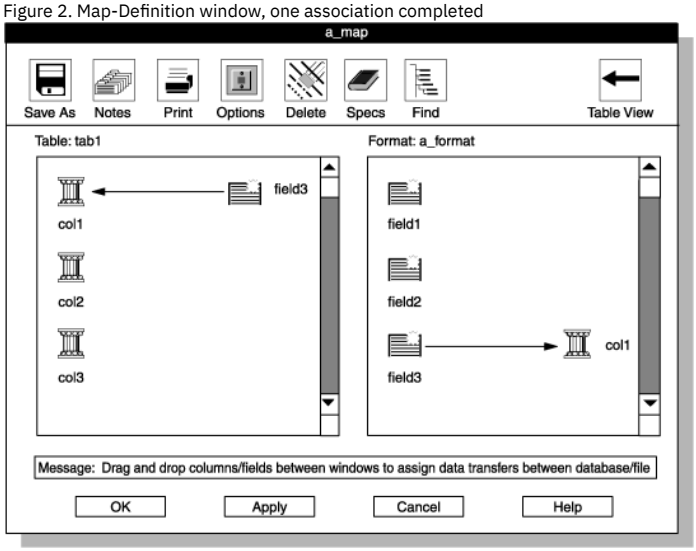
Before you can create a load map, you must create a format that describes the data file that you plan to load. For information about how to create a format, see Define formats.
Important: The HPL does not support conversion from extended type data and smart-large-object data (Ext Type data types) to non-Ext Type data types. A field that is defined as an Ext Type data type can be mapped only to an Ext Type column. For more information about Ext Type data types, see Data types allowed in a fixed format or Data types allowed in a delimited format
To create a load map:

1. Choose Components > Maps > Load Map from the HPL main window.
   The Record Maps window appears, as the following figure shows.
   Figure 1. The Load Record Maps window
   


2. Click Create in the Selection Type group.
3. Choose a name for the map and type it in the Map Name text box.
4. Type the names of the database and table where the data will be loaded in their corresponding text boxes.
   You can also click the down arrow to choose the names from a selection list. The Tables selection list includes synonyms that are valid for the local database server.
5. Type the format that describes the data file in the Format text box.
   You can also click the down arrow to choose the format from a selection list.
6. Click OK to open the Map-Definition window.
   A Map-Definition window similar to Figure 2 appears.
7. Click a column icon in the left column in the Table pane and hold the mouse button down. A box appears around the icon and its name.
8. Drag the box to a field icon in the Format pane.
   When you connect columns to fields, it does not matter whether you drag a column to a field or drag a field to a column, but you must always connect items from the left column of each pane.

   The following figure shows a Map-Definition window with this step completed.

Figure 2. Map-Definition window, one association completed



9. Repeat steps 7 and 8 for each field that you want to transfer into the database.
10. Add the options that you want, if any. For instructions, see Defining the mapping options.
11. Click OK to return to the Load Record Maps window.

Related reference:
Create a fixed format that uses carriage returns

Unload maps

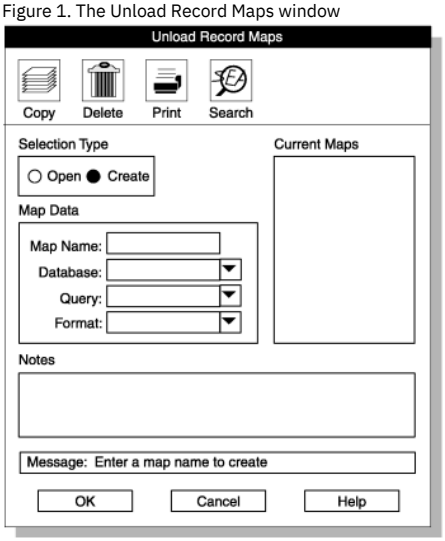
An unload map associates columns extracted from a database by a query with the fields in a data-file record. You can create an unload map from the Load Job window or from the Components menu of the HPL main window. After you define an unload map, you use it with the Unload Job window or the **onpload** utility.

- Creating an unload map
- Unload data by using functions
  If you use a function in a query to unload data, you must associate a name with the result of that function.

Creating an unload map

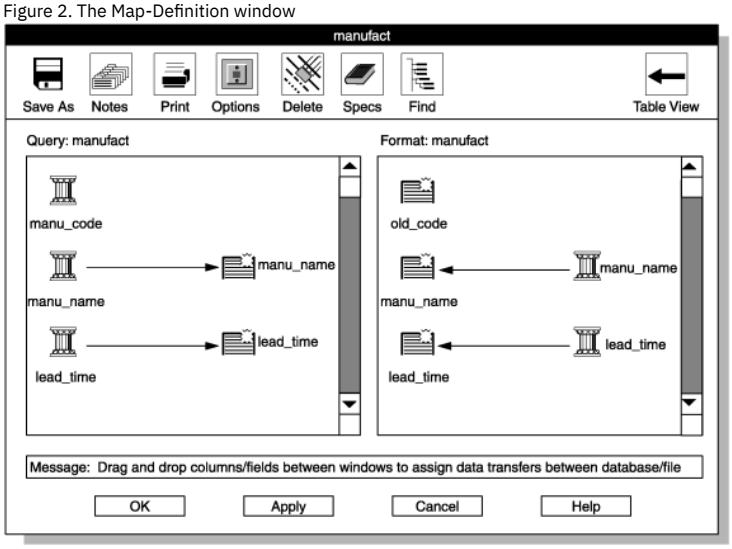
Before you can create an unload map, you must define a query on the table that will be unloaded. For instructions on how to define a query, see HPL queries.
Important: The HPL does not support conversion from extended type data and smart-large-object data (Ext Type data types) to non-Ext Type data types. An Ext Type column can be mapped only to an Ext Type field. For more information about Ext Type data types, see Data types allowed in a fixed format or Data types allowed in a delimited format.
To create an unload map:

1. Choose Components > Maps > Unload Map from the HPL main window.
   The Unload Record Maps window appears, as the following figure shows.
   Figure 1. The Unload Record Maps window



2. Click Create in the Selection Type group.
3. Choose a name for the map and type the name in the Map Name text box.
4. Type the name of the database in the Database text box. You can click the down arrow to choose a database from a selection list of databases.

5. Type the name of a query in the Query text box. You can click the down arrow to choose a query from a selection list of queries.
6. Type the format name in the Format text box. You can click the down arrow to choose a format from a selection list of formats.
7. Click OK.
   A Map-Definition window is similar to the following figure. In this figure, some of the field names match column names. The **ipload** utility automatically maps columns to fields of the same name. The direction of the arrows indicates the flow of data, as shown.
   Figure 2. The Map-Definition window



8. To map a database column to a data-file field, click the database-column icon. Drag the column to the data-file field icon that you want. An arrow links the column icon to the field icon.
9. Repeat step 8 until you have mapped all the columns you want to fields.
10. Define any mapping options as appropriate. For information about mapping options, see Mapping options.
11. Click OK to save the map and return to the Unload Record Maps window.
12. Click Cancel to return to the HPL main window.

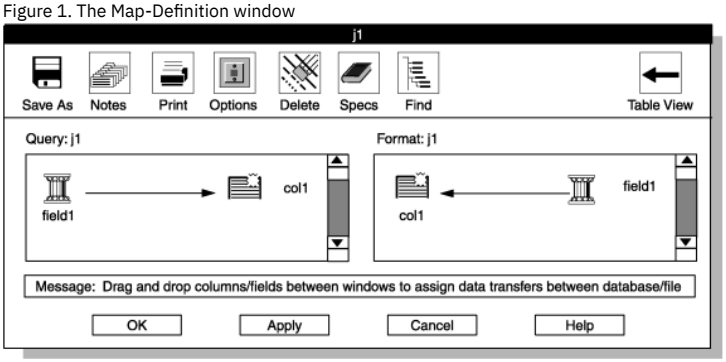
Unload data by using functions

If you use a function in a query to unload data, you must associate a name with the result of that function.

In the following example, the returned value of the function TRIM is assigned the name `field1`.

```
SELECT TRIM(col1) field1 FROM tab1
```

After submitting the query, you must attach `field1` to `col1` of the unload file manually, as the following figure shows.
Figure 1. The Map-Definition window



Mapping options

The mapping options define conversions that **onpload** applies to the data before it inserts the data into the database (for a load job) or into the data file (for an unload job). These conversions can include case conversion, text justification, data masking through picture strings, default values, and fill characters. The mapping options also allow you to replace imported data with data from other database tables.

The information from the Mapping Options window is stored in the **mapoption** table of the onpload database.

- Defining the mapping options
  This procedure describes how to specify mapping options.
- Set the mapping options
  You can set as many of the choices on the Mapping Options window as you need.

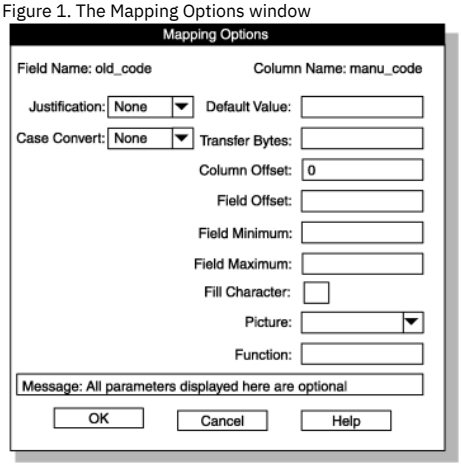
Related reference:
The onpload database

Defining the mapping options

This procedure describes how to specify mapping options.

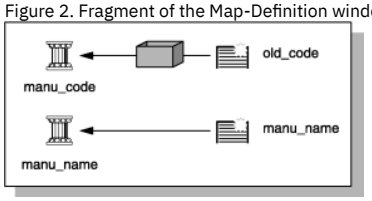
To define mapping options:

1. Display the Map-Definition window by following the steps for Creating a load map, or Creating an unload map.
2. Select the field or column (in the right column of a pane) that you want to modify.
3. Click Options.
   The Mapping Options window appears, as the following figure shows.
   Figure 1. The Mapping Options window



4. Change the options that you want.
5. When you have set all the options that you want, click OK to return to the Map-Definition window.

When you return to the map window, an options symbol (a small box) appears between the field and the column, as the following figure shows. The options symbol indicates that mapping options are in effect.
Figure 2. Fragment of the Map-Definition window showing an options symbol



Related reference:
The mapoption table in the onpload database

Set the mapping options

You can set as many of the choices on the Mapping Options window as you need.

Justification option

The Justification option positions text within a record. You can justify the text to the left or right, or you can center it.

Case Convert option

The Case Convert option converts the case of the data to the selected case. The High-Performance Loader (HPL) supports upper, lower, and proper-name conversions. For example, you can make the following conversions.

Input	Conversion type	Result
JOHN LEE SMITH	Proper Name	John Lee Smith
john lee smith	Proper Name	John Lee Smith
john lee smith	Upper	JOHN LEE SMITH
JOHN LEE SMITH	Lower	john lee smith

Default Value option

The Default Value option specifies the value that is inserted into the column when no field is mapped into that column.

Transfer Bytes option

The Transfer Bytes option specifies the number of bytes in the record field to transfer to the database column.

For variable-length format records, this number reflects the maximum size of the field. The actual number of bytes to transfer is determined by the record or field delimiters.

Column Offset option

The Column Offset option specifies the offset from the beginning of a column field at which to start transferring the data from the field of the data record. Offsets are zero based.

Field Offset option

The Field Offset option specifies the offset from the beginning of a record field at which to start transferring data to the column. Offsets are zero based.

Field Minimum and Field Maximum options

The Field Minimum and Field Maximum options specify the smallest and largest acceptable values for a numeric column. If the data in the field is outside that range, the HPL rejects the record. This option is available only for fields with numeric formats, such as integer, short, or float.

Fill Character option

The Fill Character option lets you specify a character that you use to pad the contents of a field. The fill character can be any character that you can type on the keyboard. You can specify a fill character for fixed ASCII and COBOL loads or unloads. The fill character is filled in as a trailing character.

Picture option

The Picture option lets you reformat and mask data from the field of a record before the data is transferred to the database. Picture strings, explains picture strings.

Function option

The Function option specifies a user-defined function that is called for every record that is processed. You must add the function to the dynamically linked library. For information about using custom functions, see the API interface documentation in Custom-conversion functions.

Editing options

This section discusses specialized options in the Map-Definition window.

- Using the Delete button
  You can break the association between a column and a field with the Delete button in the Map-Definition window.
- Using the Find button
  You can find a column or field in a pane with the Find button in the Map-Definition window. The **ipload** utility scrolls the selected item into view and puts a box around it. This option is useful when the list of columns or fields is so long that the pane cannot display all of the items.
- Using the Specs button
  With the Specs button, you can display the Specifications window, where you can examine the characteristics of the columns and fields in your map.

Using the Delete button

You can break the association between a column and a field with the Delete button in the Map-Definition window.

To use the Delete button:

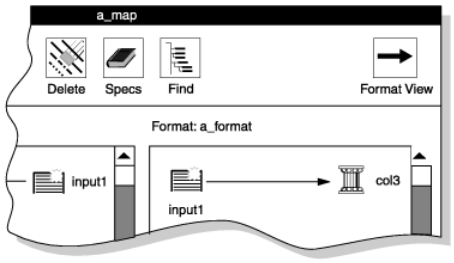
1. Click an icon in the right column of either of the panes in the Map-Definition window.
2. Click Delete to remove the arrow that connects the item to another item.

Using the Find button

You can find a column or field in a pane with the Find button in the Map-Definition window. The **ipload** utility scrolls the selected item into view and puts a box around it. This option is useful when the list of columns or fields is so long that the pane cannot display all of the items.

To use the Find button:

1. In the Map-Definition window, select either the Table pane or the Format pane.
   When you select a pane, the view indicator in the upper right corner of the window changes to show which pane you selected. The following figure shows the upper portion of the Map-Definition window after you select the Format pane.
   Figure 1. The view indicator



2. Click Find.
   The Find Node window appears, as the following figure shows.
   Figure 2. The Find Node window

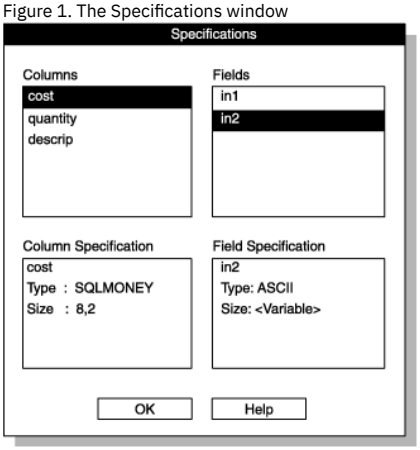
   Because the view indicator shows Format View, the Find Node window lists the fields of the data file. To see the columns of the database table, make sure that the view indicator shows Table View.

3. To select the item to find, you can use either of these methods:
   - Scroll through the list box to locate the item that you want to find and then select the item.
   - Type the name of the item that you want to find in the Selection text box.
4. Click OK. The Map-Definition window appears again. The selected field or column is highlighted with a box.

Using the Specs button

With the Specs button, you can display the Specifications window, where you can examine the characteristics of the columns and fields in your map.

The following figure shows a sample Specifications window.
Figure 1. The Specifications window



To use the Specifications window:

1. Click Specs in the Map-Definition window to display the Specifications window.
2. Select a column from the Columns list box or a field from the Fields list box or both.
   The specification boxes in the lower part of the screen display the characteristics of the selected items.
3. When you finish examining the specifications, click OK to return to the Map-Definition window.

The Specifications window displays the attributes of columns and fields. The Specifications window does not allow you to edit the attributes it displays. To change the attributes of a field, you must modify the format of the data file. (See Format options.) To change the attributes of a column, you must use appropriate SQL statements to modify the database table.

Map Views window

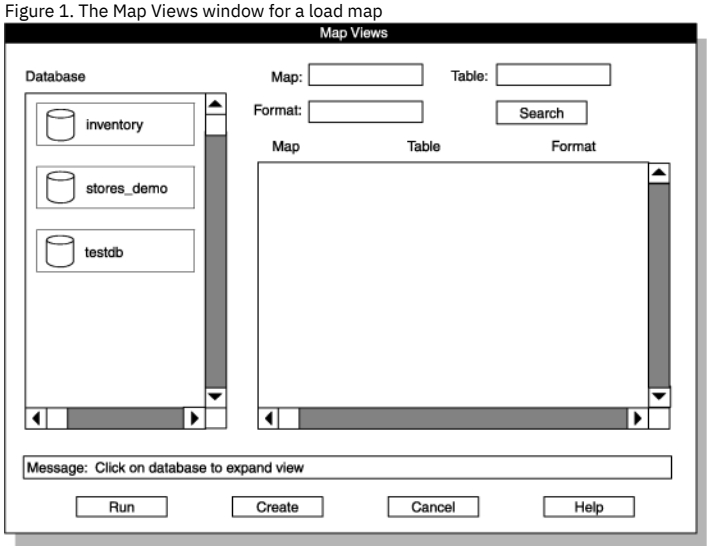
You can display a list of the components that are associated with a database in a specific project from the Map Views window. You can also create or edit a map.

The Map Views window appears in the following situations:

- If you click Map in the Load Job or Unload Job window when no map name is in the Map text box

- If you click Search in the Load Record Maps or Unload Record Maps window

The following figure shows the Map Views window for a load map.
Figure 1. The Map Views window for a load map



- Seeing the load maps of a database
- Seeing selected load maps

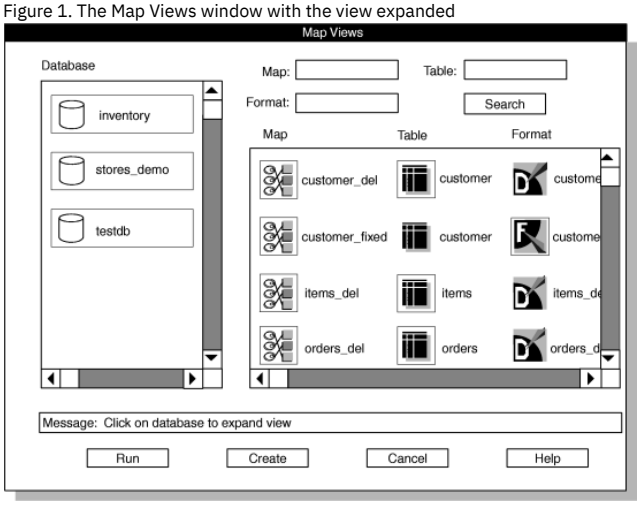
Seeing the load maps of a database

To see the load maps of a database:

1. Select a project in the HPL main window.
2. Choose Components > Maps from the HPL main window.
3. Choose Load > Map or Maps > Unload Map.
4. After the Load Record Maps or Unload Record Maps window appears, click Search.
   The Map Views window appears, as Figure 1 shows.

5. Select a database.
   The **ipload** utility displays a list of the maps associated with that database, as the following figure shows. The Table and Format columns show the database column and the format associated with each map.

   If you want to edit a specific map or format, click its button and the corresponding definition window appears.
   Figure 1. The Map Views window with the view expanded

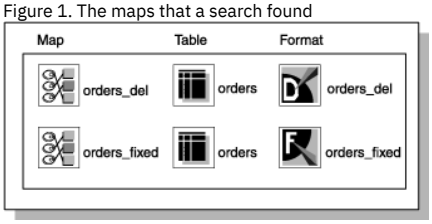


Seeing selected load maps

To see selected load maps:

1. Open the Map Views window.
2. Select a database.
3. Type the name or partial name of a map, table, or format in the Map, Table, or Format text box. You can use wildcards in the name.
4. Click Search.
   The following figure shows the maps that you find when you search for any table that includes **orders** in its name.

Figure 1. The maps that a search found



Define filters

This section describes how to create, edit, and delete filters.

- Filters
  Filters are similar to queries. However, queries select data from database tables, whereas filters select data from a data file. During the load process, **ipload** loads all of the records from a data file into a database table unless you use a filter to exclude some of the records.
- Example of using filter
- Creating a filter
- Modifying a filter
  After you create a filter, you might need to modify that filter.
- Filter views
  You can display a list of the filters and formats that are associated with a project from the Filter Views window. You can also create or edit a filter.
- Filters with code-set conversion (GLS)

Filters

Filters are similar to queries. However, queries select data from database tables, whereas filters select data from a data file. During the load process, **ipload** loads all of the records from a data file into a database table unless you use a filter to exclude some of the records.

A filter is a mechanism for prescreening data-file records for eligibility as database table entries. You can use the filter to include or exclude records explicitly during the load process. You define *match conditions* to filter the records. Match conditions are selection criteria that test one or more data-file fields for certain values or text.

You can define filters at any time. After you define a filter, you can specify it in the Load Job window. The Load Job window is illustrated in Figure 2.

Filters have the following restrictions:

- You cannot use filters with Ext Type data types.
- The DATE and DATETIME data filters can only be applied to the fixed ASCII and delimited format types.

Example of using filter

Suppose that you have a worldwide telemarketing data file that contains the name, country, yearly salary, and age of potential contacts, as the following example shows:

```
John BrownUS  125,00057
Mary SmithArgentina83,00043
Larry Little US  118,00042
Ann SouthCanada  220,00053
David PetersonFrance  175,00072
Richard NorthSpain350,00039
Nancy RichardsJapan150,00054
William ParkerEgypt200,00064
```

To create a database that includes people who earn over $100,000 a year, are over the age of 50, and live outside the United States:

1. Use the match condition **discard salary < 100,000** to exclude people who earn less than $100,000 a year. The selected records are as follows:

   ```
   John BrownUS125,00057
   Larry Little US118,00042
   Ann SouthCanada220,00053
   David PetersonFrance175,00072
   Richard NorthSpain350,00039
   Nancy RichardsJapan150,00054
   William ParkerEgypt200,00064
   ```

2. Use the match condition **keep age > 50** to include people over the age of 50. The remaining records are as follows:

   ```
   John BrownUS125,00057
   Ann SouthCanada220,00053
   David PetersonFrance175,00072
   Nancy RichardsJapan150,00054
   William ParkerEgypt200,00064
   ```

3. Use the match condition **discard country = US** to exclude people living in the United States. The remaining records are the records that match all of the restrictions:

   ```
   Ann SouthCanada220,00053
   David PetersonFrance175,00072
   Nancy RichardsJapan150,00054
   William ParkerEgypt200,00064
   ```

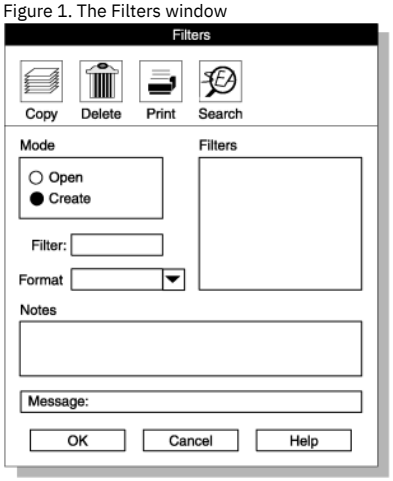
If you want to use the same data file to create a database of only those people who live in the United States, or only those people under the age of 30, simply define another filter. There is no limit to the number of filters that you can define for a data file.

Related reference:
Define filters

Creating a filter

Before you can create a filter, you must create a format that describes the data file. For information about how to create a format, see Define formats.
The **ipload** utility stores the filter information in the **filters** table of the onpload database. For more information about the **filters** table, see The filters table in the onpload database.

To create a filter:

1. Choose Components > Filter from the HPL main window.
   The Filters window appears, as the following figure shows.
   Figure 1. The Filters window
   


2. Click Create in the Mode group.
3. Choose a name for the filter and type the name in the Filter text box.
4. Type the name of an existing format in the Format text box, or click the down arrow and choose a format from the selection list.
5. Click OK.
   The Filter-Definition window appears. The following figure shows a partially completed Filter-Definition window.
   Figure 2. The Filter-Definition window
   
   From the Filter-Definition window, you can prepare a filter that specifies which data from the input file is be loaded into the database table.

   The Filter-Definition window has the following parts.

Table 1. Parts of the Filter-Definition window

Section	Description
Fields	Specifies the data-file field used in a match condition
Status	Indicates whether you want to keep or discard records that meet the match condition
Match Condition	Specifies the criteria for keeping or discarding a record
Filter Items/Status	Lists existing filter items and their status As you add match conditions, the conditions are added to this list.

- Preparing the filter definition

Related reference:

The filteritem table in the onpload database
The filters table in the onpload database

Preparing the filter definition

To prepare the filter definition:

1. Click Add in the Operation group to specify that you want to add a new match condition.
2. Type the name of the record field that you want to match in the Fields text box. You can also click the down arrow to see a selection list.
3. Click Keep or Discard in the Status group. This selection indicates whether the matching record should be entered into the database or discarded.
4. Type the match condition in the Match Condition text box by using the appropriate logical operators and match characters.
   See Match condition operators and characters for a list of the logical operators and match characters.
5. Click Perform.
6. Repeat steps 2 through 5 for each additional filter item.
7. Click OK to save the filter and return to the Filters window.
8. Click Cancel to return to the HPL main window.

Modifying a filter

After you create a filter, you might need to modify that filter.

1. Choose Components > Filter from the HPL main window to display the Filters window.
2. Click Open in the Mode group.
3. Select the filter that you want to modify.
4. Click OK to display the Filter-Definition window.
5. Click Add in the Operation group.
6. Type the name of the record field in the Fields text box.
7. Type the match condition in the Match Condition text box.
8. Click Keep or Discard in the Status group to indicate the filter status.
9. Click Perform.
10. Click OK to save your changes and return to the Filters window.
11. Click Cancel to return to the HPL main window.

- Editing an existing filter
- Adding an item to the filter
- Inserting an item into the filter sequence
- Deleting a filter

Editing an existing filter

To edit an existing filter:

1. Choose Components > Filter from the HPL main window tp display the Filters window.
2. Click Open in the Mode group.
3. Select the filter that you want to modify.
4. Click OK to display the Filter-Definition window.
5. Click Edit in the Operation group.
6. Select the filter item you want from the list of items. The field, status, and match conditions appear in their respective areas on the screen.
7. Change the information that you want.
8. Click Perform.
9. Click OK to save your changes and return to the Filters window.
10. Click Cancel to return to the HPL main window.

Adding an item to the filter

To add an item to the filter:

1. Choose Components > Filter from the HPL main window to display the Filters window.
2. Click Open in the Mode group.
3. Select the filter that you want to modify.
4. Click OK to display the Filter-Definition window.
5. Click Add in the Operation group.
6. Type the name of the record field in the Fields text box.
7. Type the match condition in the Match Condition text box.
8. Click Keep or Discard in the Status group to indicate the filter status.
9. Click Perform.
10. Click OK to save your changes and return to the Filters window.
11. Click Cancel to return to the HPL main window.

Inserting an item into the filter sequence

To insert an item in the filter sequence:

1. Choose Components > Filter from the HPL main window to display the Filters window.
2. Click Open in the Mode group.
3. Select the filter that you want to modify.
4. Click OK to display the Filter-Definition window.
5. Click Insert in the Operation group.
6. From the list of items, select the filter item before which you want to insert the new item.
7. Type the name of the record field in the Fields text box.
8. Type the match condition in the Match Condition text box.
9. Click Keep or Discard in the Status group to indicate the filter status.
10. Click Perform to insert the new item before the selected filter item in the Filter Items list box.
11. Click OK to save your changes and return to the Filters window.
12. Click Cancel to return to the HPL main window.

Deleting a filter

To delete a filter:

1. Choose Components > Filter from the HPL main window to display the Filters window.
2. Click Open in the Mode group.
3. Select the filter that you want to edit.
4. Click OK to display the Filter-Definition window.
5. Click Delete in the Operation group.
6. Select the item that you want to delete from the list of filter items.
7. Click Perform.
8. Click OK to save your changes and return to the Filters window.
9. Click Cancel to return to the HPL main window.

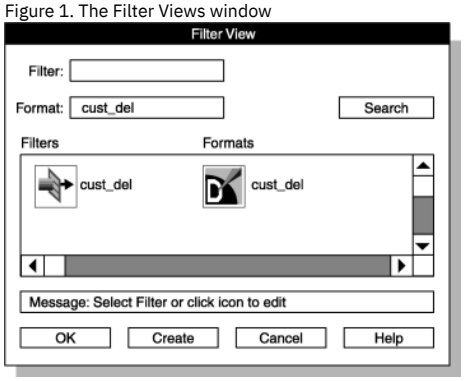
Filter views

You can display a list of the filters and formats that are associated with a project from the Filter Views window. You can also create or edit a filter.

The Filter Views window appears in the following situations:

- If you click Filter in the Load Job window when no filter name is in the Filter text box
- If you click Search in the Filters window

The following figure shows the Filter Views window. Views windows discusses the use of Views windows.
Figure 1. The Filter Views window



Filters with code-set conversion (GLS)

When you use a filter to select or discard data during the load, the High-Performance Loader (HPL) interprets the filter specification in the code set of the database server. The filtering process on data that undergoes code-set conversion occurs in the following order:

1. The **onpload** utility converts the input data to the code set of the database server.
2. The **onpload** utility performs the filtering operation.

If the code-set conversion process creates lossy errors, then the output of the filter operation can be unexpected. For information about lossy errors and how to define or evaluate a code-set conversion specification, see the *IBM® Informix® GLS User's Guide*.

Unload data from a database

This section describes the Unload Job window.

- Unload jobs
  An unload job converts IBM Informix database records to a specified format and then unloads those records to a file, tape, pipe (UNIX only), or device array.
- Components of the unload job
- The Unload Job windows
  You can create an unload job or select an existing job for editing from the Unload Job Select window.
- Generate options for an unload job
  Instead of individually creating the components that are required on the Unload Job window, you can use the Generate options to create an unload job.

Related concepts:
The HPL data-unload process
Load Job and Unload Job windows

Unload jobs

An unload job converts IBM® Informix® database records to a specified format and then unloads those records to a file, tape, pipe (UNIX only), or device array.

You can run an unload job from the Unload Job window of **ipload**, or you can run the **onpload** utility from the command line.

Related reference:
The onpload utility

Components of the unload job

Before you can unload data, you must first define the following components of the unload job:

- The device array that receives the unloaded data.
- The format that describes the organization of the data file into which you are unloading data.
- The query that extracts the records that you want from the database.
- The unload map that describes the relationship between the columns of a database table and the fields of the data-file record.
  The map also specifies any necessary data translations, such as case conversion and justification.

You can define these components in the following ways:

- Define each component from the Unload Job window.
- Define each component individually from the Components menu.
- Use the Generate Job option from the Components menu.
- Use the Generate button in the Unload Job window.

- Choose the database server
  You must run the unload job on the *target server*. The target server is the database server that contains the database from which you unload the data. The database must be on the same database server as onpload that extracts data from it. You can run **ipload** on any database server on your network.
- Run multiple jobs
  You can run multiple unload jobs concurrently.

Related concepts:
Define device arrays
Related reference:
Define formats

Define maps
The Generate options of the ipload utility

Choose the database server

You must run the unload job on the *target server*. The target server is the database server that contains the database from which you unload the data. The database must be on the same database server as onpload that extracts data from it. You can run **ipload** on any database server on your network.

Run multiple jobs

You can run multiple unload jobs concurrently.

However, because the High-Performance Loader (HPL) is designed to use as many system resources as possible, running concurrent jobs might overload the system. If you are using a UNIX **cron** job to run the load and unload jobs, let one job finish before you start the next.

The Unload Job window displays the target and onpload database servers in the upper right corner of the display.

The Unload Job windows

You can create an unload job or select an existing job for editing from the Unload Job Select window.

From the Unload Job window, you can also create or modify the components of an unload job and run the unload job. You can change unload options before you run the unload job. The unload options include the isolation level and the maximum number of errors to permit before **onpload** stops the unload job.

The **ipload** utility stores the information about the unload job in the **session** table of the onpload database. The **session** table draws information from other onpload tables, such as **maps**, **formats**, and so on.

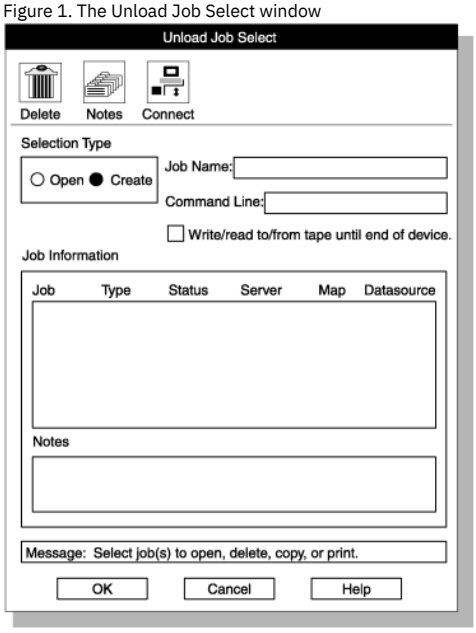
- Creating an unload job
  Use the Unload Job Select and Unload Job windows to create an unload job.
- Run the unload job
- Specify to write to the end of the tape
  On the Unload Job Select window, you can specify to write to the tape until the end of the device with the Write/read to/from tape until end of device check box. When a tape device is full, you are prompted to provide the next tape, until the unload job is complete.
- The command-line information
  If you select an existing job in the Unload Job Select window, the Command Line text box shows the **onpload** command that **ipload** generated for that unload job.
- Changing the unload options
- Editing an unload job
  After you save an unload job, you can return to the unload job and modify it.

Related reference:
The onpload database

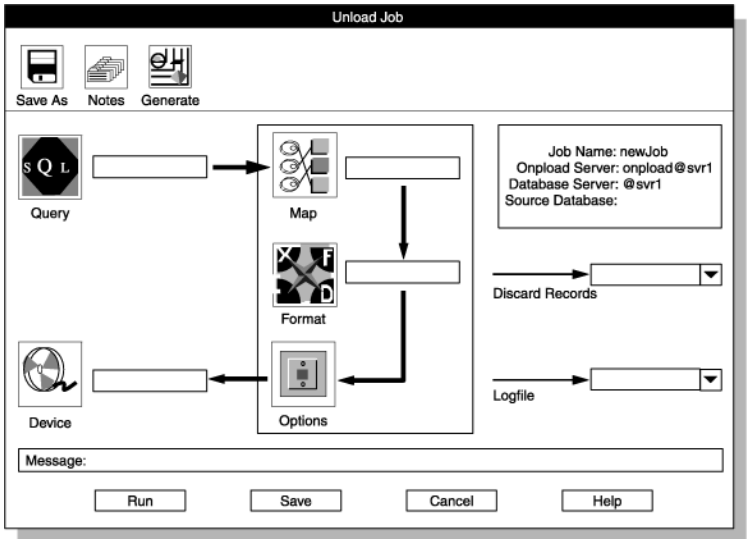
Creating an unload job

Use the Unload Job Select and Unload Job windows to create an unload job.

To create an unload job:

1. Choose Jobs > Unload from the HPL main window.
   The Unload Job Select window appears, as the following figure shows.
   Figure 1. The Unload Job Select window
   


2. Click Create in the Selection Type group.
3. Choose a name for this unload job and type the name in the Job Name text box.
4. Optionally check the Write/read to/from tape until end of device check box. For more information, see Specify to write to the end of the tape.
5. Click OK.
   The Unload Job window appears, as the following figure shows. The ipload utility windows, provides detailed descriptions of the buttons in the Unload Job window.
   Figure 2. The Unload Job window



6. Type appropriate values for all of the unload components. If you click a component button, the corresponding view window opens, and you can create or select the component.
7. Specify the file that contains rejected record by using one of these methods:
   - Type the name of the rejected file in the Discards Records text box.
   - Click the down arrow next to the Discard Records text box to select the file name from the file-selection list.
8. Select the file that contains the unload status log by using one of these methods:
   - Type the name of the log file in the Logfile text box.
   - Click the down arrow next to the Logfile text box to select a file name from the File-Selection window.
9. Click Options to change unload options. For more information, see Changing the unload options.
10. Click Save to save this unload job. (If you click Run to run the job immediately, the job is saved automatically.)
11. Now you can either run the unload job or exit and run the job later.
    - Click Run to run the job.
    - Click Cancel to exit to the Unload Job Select window.

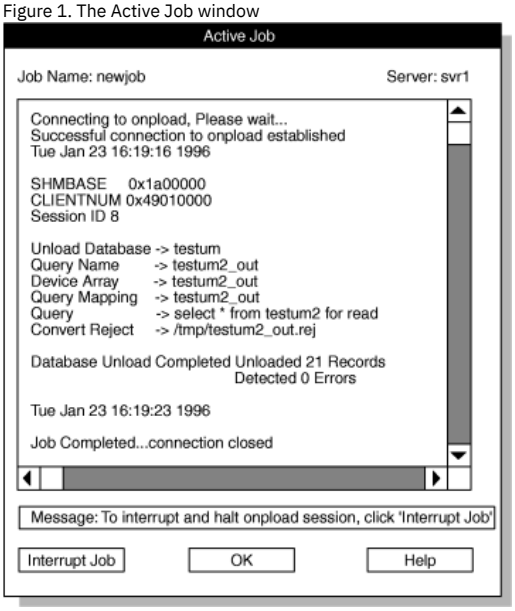
Important: Use Ext Type String Length data type or Ext Type Binary Length data type if you unload data that contains null UDT values.

Run the unload job

If you click Run in the Unload Job window, the Active Job window appears, as the following figure shows. The Active Job window displays the progress of your job and indicates when the job completes. When the Active Job window indicates that the job is complete, click OK to return to the Unload Job Select window.

The information that **onpload** displays in the Active Job window is also stored in the log file whose name you selected in step 8.

Figure 1. The Active Job window



- Problems during an unload job
  If you encounter any problems during the unload, examine the various files that **onpload** creates.

Related reference:
View the status of a load job or unload job

Problems during an unload job

If you encounter any problems during the unload, examine the various files that **onpload** creates.

Important: If a write to a file fails because a disk is out of space, the operating system does not return information about how much of the write succeeded. In this situation, the **onpload** utility cannot accurately report the number of records that were written to disk. Thus, the number of records that are logged as unloaded in the log file is imprecise.
Related reference:
The HPL browsing options

Specify to write to the end of the tape

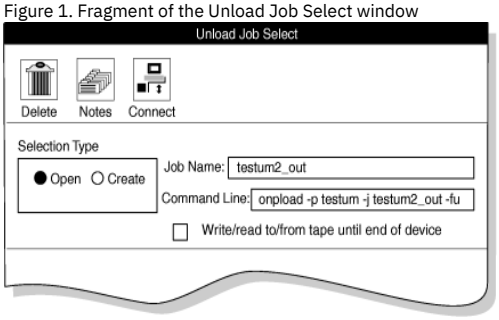
On the Unload Job Select window, you can specify to write to the tape until the end of the device with the Write/read to/from tape until end of device check box. When a tape device is full, you are prompted to provide the next tape, until the unload job is complete.

Important: If you select this option, you must also select it when loading from the Load Job window or specify the **-Z** option from the command line; otherwise, the loaded and unloaded data might be inconsistent.
If you check this check box, it supersedes any tape size information you enter in the Device-Array Definition window or at the command line.
Important: You must provide the same tapes in the same order on the same devices for both unload jobs and load jobs to ensure consistency.

The command-line information

If you select an existing job in the Unload Job Select window, the Command Line text box shows the **onpload** command that **ipload** generated for that unload job.

The following figure shows the Command Line portion of an Unload Job Select window. The Command Line text box displays the **onpload** command generated for the job shown in Figure 1.
Figure 1. Fragment of the Unload Job Select window



The command line, **onpload -p testum -j testum2_out -fu**, contains the following arguments.

-p testum
: The project where the job is stored.

-j testum2_out
: The name of the job.

-fu
: The job that unloads (rather than loads) data.

You can copy the **onpload** command from the Command Line text box and paste it at a system prompt to run the unload job. If you need to run the unload job multiple times (for example, every evening at 5:00 p.m.), you can save the **onpload** command and run it later.

You do not need to start **ipload** to run a job from the system prompt. Both **ipload** and **onpload** use the **onpload** database, but each one uses it independently.

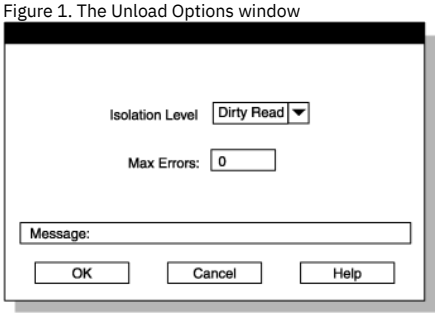
Changing the unload options

The Unload Options window contains the following options.

Table 1. The Unload Options window options

Option	Description
Isolation Level	The criteria for how the query selects records. The four levels of isolation (from highest to lowest) are as follows: • Committed • Cursor Stability • Repeatable Read • Dirty Read The higher the isolation level, the lower the unload performance. For a more detailed definition of isolation levels, see the *IBM® Informix® Guide to SQL: Syntax*.
Max Errors	The maximum number of error conditions to be encountered. If the number of unload errors exceeds this number, the unload job stops.

To change unload options:

1. Display the Unload Job window. See the instructions for Creating an unload job.
2. Click Options.
   The Unload Options window appears, as the following figure shows.
   Figure 1. The Unload Options window
   


3. Change the options that you want.
4. Click OK to return to the Unload Job window.

Editing an unload job

After you save an unload job, you can return to the unload job and modify it.

To edit an unload job:

1. Choose Jobs > Unload from the HPL main window.
2. Click Open in the Selection Type group.
3. Select a job from the Job Information list box.
4. Click OK to display the Unload Job window.
5. Make the appropriate changes to the entries in the Unload Job window.
6. Click Options to change unload options. For more information, see Changing the unload options.
7. Click Save to save this unload job.
8. Now you can either run the unload job or exit and run the job later.
   - Click Run to run the job.
   - Click Cancel to exit.

Generate options for an unload job

Instead of individually creating the components that are required on the Unload Job window, you can use the Generate options to create an unload job.

You can click Generate in the Unload Job window, or you can choose Components > Generate from the HPL main window.

The Generate options do not give you as much flexibility as the Unload Job window, but the options let you create the components quickly. In addition, the Generate options let you create formats (Binary, Fixed Internal, and No Conversion) that are not available from the Format-Definition window.

Related reference:
The Generate options of the ipload utility

Load data to a database table

This section describes the load process.

- Load jobs
  A load job loads data from a set of one or more files into a single database table. A record format, which defines each field of a record, specifies the layout of the input data. A load map specifies how the record fields are mapped to the columns of the target table. During the load process, the **onpload** utility converts data from record field to table column.
- Components of the load job
  The High-Performance Loader (HPL) lets you define the individual components of a data load individually or lets you use the generate option to define the components automatically.
- The Load Job windows
  You can create, save, and run a load job from the Load Job Select window and the Load Job window. The Load Job window visually represents the various components of a load. After you select the components, you can save the load job for future use or run it immediately.
- Generate options for a load job
  Instead of individually creating the components that are required on the Load Job window, you can use the Generate options to create a load job.

Related concepts:
Load Job and Unload Job windows

Load jobs

A load job loads data from a set of one or more files into a single database table. A record format, which defines each field of a record, specifies the layout of the input data. A load map specifies how the record fields are mapped to the columns of the target table. During the load process, the **onpload** utility converts data from record field to table column.

Components of the load job

The High-Performance Loader (HPL) lets you define the individual components of a data load individually or lets you use the generate option to define the components automatically.

The components of the load job specify:

- The device array where the source data files resides
- The format of the data files
- The filter that accepts or rejects source-file records for the load
- The map that specifies the relationship between the data-file format and the database table schema

When you run a load job, you select which individual components to use. The collection of the various components for a specific load is called the load job. You can assign a name to a load job, save the job, and then retrieve and rerun it as often as you need to. You can modify an existing job or save it under another job name.

You can define as many different load jobs as you need. You can group your load jobs under one or more projects to make the tasks easier to manage.

- Choose the database server
  You must run the load job on the *target server*. The target server is the database server that contains the database into which you load the data. The target database must be on the same database server as the **onpload** program that updates it.
- Run multiple jobs
  You can run only one express-load job at a time on the same table, although you can run multiple unload jobs concurrently. Because the High-Performance Loader (HPL) is designed to maximize the use of system resources, running concurrent jobs might overload the system.
- Prepare user privileges and the violations table
  You must make sure that the user who runs a load job has sufficient privileges to manage the constraints and the violations table.

Related reference:
Define onpladm utility jobs

Choose the database server

You must run the load job on the *target server*. The target server is the database server that contains the database into which you load the data. The target database must be on the same database server as the **onpload** program that updates it.

Tip: The onpload database and the **ipload** interface can be on different computers. You can run the **ipload** interface on any computer that can connect to the database server that contains the onpload database.

Run multiple jobs

You can run only one express-load job at a time on the same table, although you can run multiple unload jobs concurrently. Because the High-Performance Loader (HPL) is designed to maximize the use of system resources, running concurrent jobs might overload the system.

If you are using a UNIX **cron** job to run the load or unload jobs, let one job finish before you start the next.

Prepare user privileges and the violations table

You must make sure that the user who runs a load job has sufficient privileges to manage the constraints and the violations table.

The following table summarizes the actions that you must take. The following sections discuss these actions in more detail.

Table Status	User Privileges	Action
Owned by user		No further action is required.
Not owned by user	User has DBA privileges on the table.	No further action is required.
Not owned by user	User does not have DBA privileges on the table.	User must have: • Resource privileges on database. • Alter privileges on table. Owner must start violations table.

For detailed information about user privileges and violations tables, see the *IBM® Informix® Guide to SQL: Syntax* and the *IBM Informix Guide to SQL: Reference*.

- Set user constraints
  To modify any constraint, index, or trigger, a user must have both Alter privileges on the table and the Resource privilege on the database. The user must also have these privileges to start or stop a violations table. You use the GRANT statement to set these privileges.
- Manage the violations and diagnostics tables

Set user constraints

To modify any constraint, index, or trigger, a user must have both Alter privileges on the table and the Resource privilege on the database. The user must also have these privileges to start or stop a violations table. You use the GRANT statement to set these privileges.

Manage the violations and diagnostics tables

You can turn on or turn off the generation of constraint-violation information. If you turn on the generation of constraint-violation information, **onpload** writes the information to the violations and diagnostics tables.

The High-Performance Loader (HPL) manages the violations and diagnostics tables in the following manner:

1. Starts the load job.
2. Starts the violations and diagnostics tables if they do not exist. (If a violations and diagnostics table exists, the HPL uses that table).
   The HPL uses the following SQL statement to start the violations table:

   ```
   START VIOLATIONS TABLE FOR tablename
   ```

3. Performs the load job.
4. Stops the violations and diagnostics tables if they were started at step 2.
   The HPL uses the following SQL statement to stop the violations and diagnostics tables:

   ```
   STOP VIOLATIONS TABLE FOR tablename
   ```

5. Drops the violations table if the violations table is empty.

The START VIOLATIONS TABLE statement creates the violations and diagnostics tables and associates them with the load table. The STOP VIOLATIONS TABLE statement dissociates the violations and diagnostics tables from the load table.

The violations table (***tablename*_vio**) and the diagnostics table (***tablename*_dia**) are always owned by the owner of the table with which they are associated. The Resource privilege lets a user start and stop a violations table, but it does not let the user drop a table that the user does not own. Thus, the HPL cannot drop the violations table in step 5 if the user is not the owner.

Failure to drop the violations table does not cause the load job to fail. However, this failure leaves in the database a violations table that is not associated with a table. If the user tries to run the job again, the START VIOLATIONS TABLE statement in step 2 fails because the table ***tablename*_vio** exists.

To solve this problem, the owner of the table or the database administrator must explicitly create the violations and diagnostics tables by using the START VIOLATIONS statement. When the owner creates the violations table, the following actions take place:

- In step 2, the HPL uses the existing violations table.
- In step 4, the HPL does not stop the violations table because the table was not started in step 2.
- In step 5, the HPL does not drop the violations table because the user does not own the table.

After the load job is complete, an active violations table remains in the database. This table might be empty, but does no harm. When the user runs the load job a second time, the violations table is available, and the load job succeeds.

The Load Job windows

You can create, save, and run a load job from the Load Job Select window and the Load Job window. The Load Job window visually represents the various components of a load. After you select the components, you can save the load job for future use or run it immediately.

The **ipload** utility assigns path names for the log files that document the load and that capture records that do not pass the specified filter or that do not pass conversion.

When you use **ipload** to create a job, **ipload** stores information for the job in a row in the **session** table of the onpload database. The **ipload** utility stores information about the components of the load job in other tables of the onpload database, including **format**, **maps**, **filters**, and so on. When you use the **onpload** command, columns in the **session** table reference the components to assemble the information necessary for the job.

- Creating a load job
  Use the Load Job Select window to create a load job or select an existing job to edit.
- Run the load job
- Specify to read to the end of the tape
  From the Load Job Select window, you can specify to read from the tape until the end of the device with the Write/read to/from tape until end of device check box. When a tape device is empty, you are prompted to provide a new tape, until the load job is complete.
- The command-line information
  If you select an existing job in the Load Job Select window, the Command Line text box shows the **onpload** command that **ipload** generated for that load job.
- Changing the load options
- Editing a load job
  After you create and save a load job, you can later return and modify that load job.

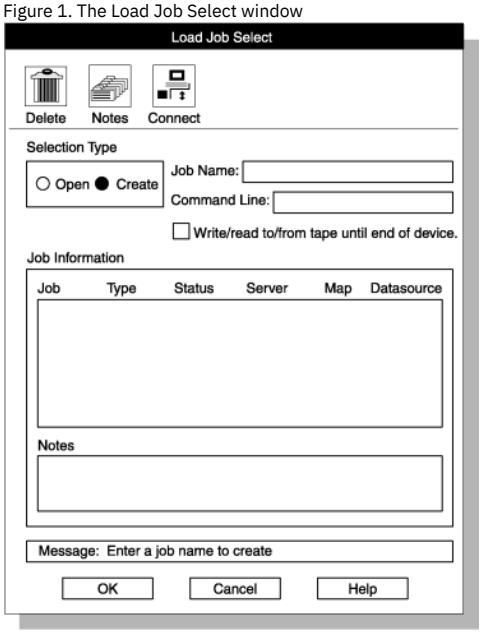
Creating a load job

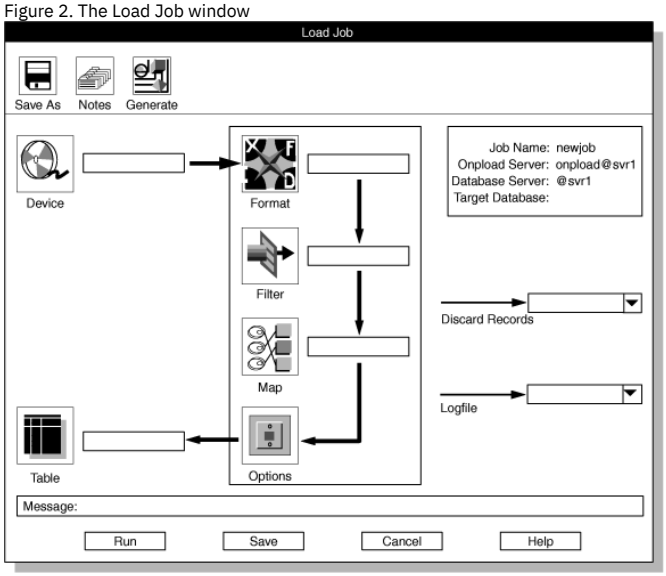
Use the Load Job Select window to create a load job or select an existing job to edit.

To create a load job:

1. Choose Jobs > Load from the HPL main window.
   The Load Job Select window appears, as the following figure shows.
   Figure 1. The Load Job Select window



2. Click Create in the Selection Type group.
3. Select a name for the job and type it in the Job Name text box.
4. Optional: Check the Write/read to/from tape until end of device check box. For more information, see Specify to read to the end of the tape.
5. Click OK.
   The Load Job window appears, as the following figure shows.
   Figure 2. The Load Job window



6. Type the appropriate values for the components of the load.
   The HPL ipload utility icon buttons describes the icons that represent the components of the load. For detailed information about these components, see the individual topics on device arrays, formats, filters, and maps.
7. Select a base name for the files that contain rejected records and type it in the Discard Records text box. Reviewing records that the conversion rejected gives information about rejected records.
8. Choose a name for the file that contains the load job status log and type it in the Logfile text box. For more information about the log file, see View the status of a load job or unload job.
9. Click Options to change the load options. For more information about these options, see Changing the load options.
10. Click Save to save this load job. (If you click Run to run the job immediately, the job is saved automatically.)
11. Now you can either run the load job or exit and run the job later.
    - Click Run to run the job.

- Click Cancel to exit to the Load Job Select window.

Run the load job

If you click Run in the Load Job window, the Active Job window appears, as Figure 1 shows. The Active Job window displays the progress of your job and indicates when the job completes. When the Active Job window indicates that the load job is complete, click OK to return to the Load Job Select window.
Tip: Before you run a load job, you might want to view the data-file records according to a specified format to check your definitions.
After you run an express-mode load, you must make a level-0 backup before you can access the table that you loaded.

- Make a level-0 backup
  Express-mode loads do not log loaded data. After an express-mode load, **onpload** sets the table to read-only as a protective measure. To make the table available for write access, you must do a level-0 backup for all the dbspaces that the fragments of the loaded table occupy. The level-0 backup allows data recovery for the table in case of future database corruption.
- Problems during a load job
  If you encounter any problems during the load, examine the various files that **onpload** creates.

Related concepts:
Preview data-file records

Make a level-0 backup

Express-mode loads do not log loaded data. After an express-mode load, **onpload** sets the table to read-only as a protective measure. To make the table available for write access, you must do a level-0 backup for all the dbspaces that the fragments of the loaded table occupy. The level-0 backup allows data recovery for the table in case of future database corruption.

If you do not need to provide for data recovery, you can use /dev/null as the backup device for the level-0 backup. This strategy makes the table available for write access without actually backing up the data. If a user attempts to write into the table before you make a level-0 backup, the database server issues an error message.

If you run several express-load jobs on different tables in a database, you can complete all of the loads before you perform the level-0 backup. However, if you try to do a second load on the same table without making a level-0 backup, the database server issues an error message.

For discussions of table fragments and dbspaces, see the *IBM® Informix® Administrator's Guide*. For information about making backups, see the *IBM Informix Backup and Restore Guide*.

Related concepts:
How the express and deluxe modes work

Problems during a load job

If you encounter any problems during the load, examine the various files that **onpload** creates.

Important: Because of operating-system limitations, the **onpload** utility cannot load successfully from a file (on disk) that is larger than 2 GB on a platform that is less than a 64-bit platform. If you try to read a file that is larger than 2 GB, **onpload** HPL fails only after it processes the first 2 GB of data. The HPL log file reports the following error:

```
Cannot read file /some_dir/a_long_file - aio error code 27
```

Related reference:
The HPL browsing options

Specify to read to the end of the tape

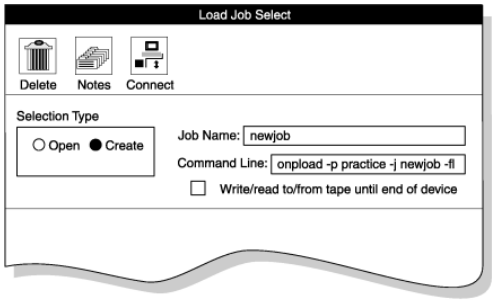
From the Load Job Select window, you can specify to read from the tape until the end of the device with the Write/read to/from tape until end of device check box. When a tape device is empty, you are prompted to provide a new tape, until the load job is complete.

Important: If you select this option, you must also select it when unloading from the Unload Job window, or specify the **-Z** option from the command line; otherwise, the loaded and unloaded data might be inconsistent.
If you check this check box, it supersedes any tape size information you enter in the Device-Array Definition window or at the command line.
Important: You must provide the same tapes in the same order on the same devices for both the unload jobs and the load jobs to ensure consistency.

The command-line information

If you select an existing job in the Load Job Select window, the Command Line text box shows the **onpload** command that **ipload** generated for that load job.

The following figure shows the Command Line portion of a Load Job Select window. The Command Line text box displays the **onpload** command generated for the load job that Figure 3 shows.
Figure 1. Fragment of the Load Job Select window



The command line, **onpload -p practice -j newjob -fl**, contains the following arguments.

-p practice
: The project where the job is stored.

-j newjob
: The name of the job.

-fl
: The job that loads (rather than unloads) data.

You can copy the **onpload** command from the Command Line text box and paste it at a system prompt to run the load job. If you need to run the load job multiple times, you can save the **onpload** command and run it later.

You do not need to start **ipload** to run a job from the system prompt. The **ipload** and **onpload** utilities both use the onpload database, but each utility uses it independently.

Changing the load options

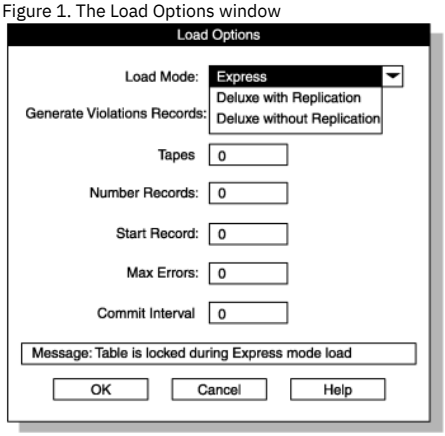
Before you run a load job, you can review or change any load options. The load options include specifying the number of records to load, the starting record number, and the loading mode.
The **ipload** utility stores option information in the **session** table of the onpload database.

The Load Options window contains the following option text boxes.

Table 1. The Load Options window options

Option	Description
Load Mode	The mode for the load: express, deluxe, or deluxe without replication
Generate Violations Records	Whether or not to generate violations records
Tapes	The number of tapes that contain source data
Number Records	The number of records to process in the data file
Start Record	The record number in the data file from which to start loading
Max Errors	The maximum number of error conditions to be encountered If the number of load errors exceeds this number, the load stops.
Commit Interval	The number of records to load before logging the transaction If you set the commit interval to `0`, **onpload** uses the default value of `10`. You can use this option only with deluxe mode.

To change load options:

1. Display the Load Job window. See Creating a load job.
2. Click Options.
   The Load Options window appears, as the following figure shows.
   Figure 1. The Load Options window
   


3. Change the options that you want.
4. Click OK to return to the Load Job window.

Editing a load job

After you create and save a load job, you can later return and modify that load job.

To edit a load job:

1. Choose Jobs > Load from the HPL main window to display the Load Job Select window.
2. Click Open in the Selection Type group.
3. Select a job from the Job Information list box.
4. Click OK to display the Load Job window.
5. Make appropriate changes to the entries in the Load Job window.
6. Click Options to change load options.
7. Click Save to save this load job.
8. Run or cancel the load, as follows:
    - Click Run to run the data load.
    - Click Cancel to exit.

Generate options for a load job

Instead of individually creating the components that are required on the Load Job window, you can use the Generate options to create a load job.

You can click Generate in the Load Job window, or you can choose Components > Generate Job from the HPL main window.

The Generate options do not give you as much flexibility as creating each component individually, but these options let you create the components quickly. (After you generate the components, you can edit the components individually by accessing them through the Components menu.) In addition, the Generate options let you create formats (Fixed Internal and No Conversion) that are not available from the Format-Definition window.

Generate options for a load job

Overview of the ipload Generate options

Use the generate options of **ipload** to automatically generate components of a load or unload job. The generate options can save you time when you create formats, maps, queries, and load and unload jobs.

When you generate a load or unload job for a database, **ipload** creates a format for the data file and a map that associates the columns of the table with the fields of the data-file records. Although the generated components might not match your database schema or data-file records exactly, the components created by the generate options provide useful starting points for building HPL components. After you generate default components, you can modify the components to match your specific needs.

Tasks that generate load or unload components

Use the **ipload** utility to perform the following tasks:

- Generate load components from the Load Job window.
- Generate unload components from the Unload Job window.
- Generate both load and unload components from the Components menu.

Generate from the Load Job window

Use the Generate button in the Load Job window to save time when the format of the data file corresponds to the format of the database table.

When you generate from the Load Job window, **ipload** makes the following assumptions about the file (or device array) that contains the data:

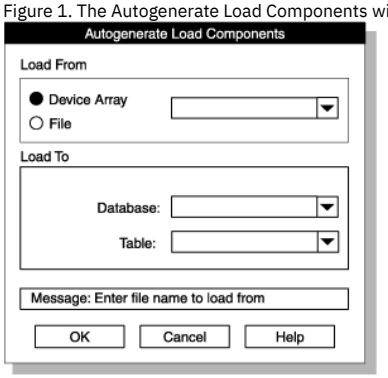
- The file is an ASCII file.
- The file uses the same locale as the database.
- The file uses a vertical bar (|) for the field delimiter and a new line for the record delimiter.
- The fields in each record of the file correspond one-to-one to the columns of the target table.
- All records in the file should be loaded.

- Generating a job from the Load Job window
  When you generate from the Load Job window, **ipload** creates a format, a map, a job, and, if needed, a device array.

Generating a job from the Load Job window

When you generate from the Load Job window, **ipload** creates a format, a map, a job, and, if needed, a device array.

To generate a job from the Load Job window:

1. Choose Jobs > Load from the HPL main window to display the Load Job Select window.
2. Click Create in the Selection Type group.
3. Select a name for the load job and type it in the Job Name text box.
4. Click OK to display the Load Job window.
5. Click Generate.
   The Autogenerate Load Components window appears, as the following figure shows.
   Figure 1. The Autogenerate Load Components window
   


6. Click Device Array or File to indicate the location of the source data
   - To load from an existing device array, click Device Array and type the name of the device array.
   - To load from a file, click File and type the full path name of the file. The **ipload** utility automatically generates a device array that includes the file.
7. In the Load To group, type the name of the database and table that will receive the data.
8. Click OK to generate the components of the load and return to the Load Job window.
9. If needed, click Filter to prepare a filter.
10. If you want, change the path names in the Discard Records and Logfile text boxes.
11. Click Save to save the components and the job.
12. Click Run to run job or Cancel to exit.

Generate from the Unload Job window

Use the Generate button in the Unload Job window to save time when the format of the data file is similar to the format of the database table.

When you generate from the Unload Job window, **ipload** makes the following assumptions about the file (or device array) into which the data is unloaded:

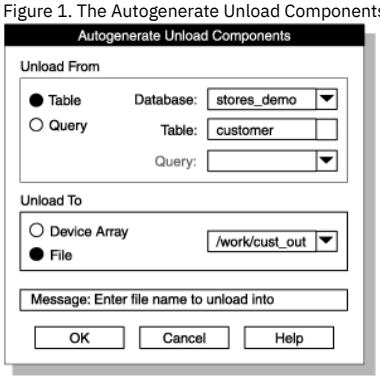
- The file is an ASCII file.
- The file uses the same locale as the database.
- The file uses a vertical bar (|) for the field delimiter and a new line for the record delimiter.

- Generating a job that uses a query
  When you generate from the Unload Job window, **ipload** creates a format, a map, a job, and, if needed, a device array. You can generate an unload job that uses a query to select from one or more tables or that unloads an entire table.
- Generating a job that unloads an entire table

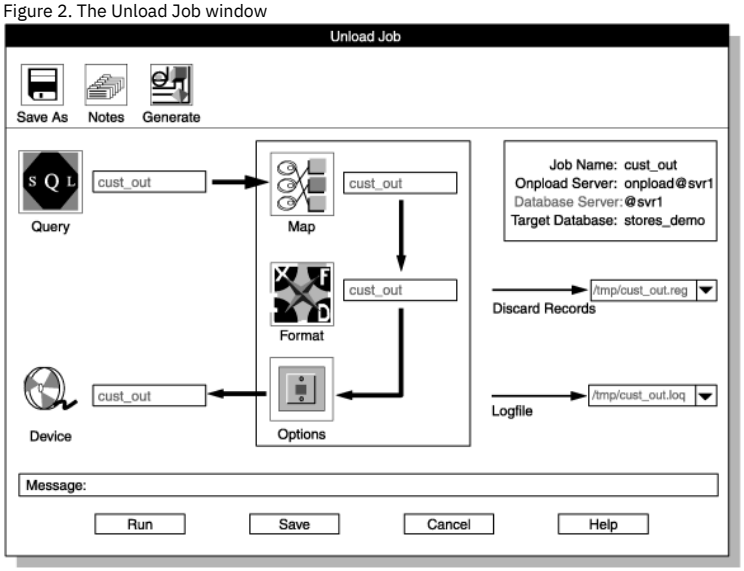
Generating a job that uses a query

When you generate from the Unload Job window, **ipload** creates a format, a map, a job, and, if needed, a device array. You can generate an unload job that uses a query to select from one or more tables or that unloads an entire table.

To generate a job that uses a query

1. Follow the instructions in Creating a query to create a query.
2. Choose Job > Unload from the HPL main window to display the Unload Job Select window.
3. Click Create in the Selection Type group.
4. Select a name for the unload job and type it in the Job Name text box.
5. Click OK to display the Unload Job window.
6. Click Generate.
   The Autogenerate Unload Components window appears, as the following figure shows.
   Figure 1. The Autogenerate Unload Components window
   


7. Click Query in the Unload From group.
8. Enter the name of the query. You can use the down arrow to see selection lists. When you unload from a table, you do not enter a query.
9. Click Device Array or File in the Unload To group.
   - If you click Device Array, you can use the down arrow to see a list of the available device arrays.
   - If you click File, **ipload** creates a device array of the same name as the unload job and inserts the specified file into that device array.

   Important: If you are executing **onpload** from the command line during an unload job, you must first create the file.
10. Click OK to generate the components of the unload job.
    The display returns to the Unload Job window. The **ipload** utility completes the Unload Job window. If you chose **cust_out** for the unload job name (step 4), the Unload Job window appears as the following figure shows.
    Figure 2. The Unload Job window
    


11. Click Save to save this Unload Job. You can click Run to run the job, or click Cancel to exit and run the job later.
12. To run the job, click Run to display the Active Job window.
13. When the Active Job window displays `Job Completed`, click Cancel to return to the main HPL window.

Generating a job that unloads an entire table

To generate a job that unloads an entire table:

1. Choose Jobs > Unload from the HPL main window to display the Unload Job Select window.
2. Click Create in the Selection Type group.
3. Choose a name for the unload job and type it in the Job Name text box.
4. Click OK to display the Unload Job window.
5. Click Generate.

The Autogenerate Unload Components window appears, as Figure 1 shows.

6. Click Table in the Unload From group.
7. Enter the database that you want in the Database text box and the table that you want in the Table text box. You can use the down arrows to see selection lists. When you unload from a table, you do not enter a query.
8. Click Device Array or File in the Unload To group.
   - If you click Device Array, you can use the down arrow to see a list of the available device arrays.
   - If you click File, **ipload** creates a device array of the same name as the unload job and inserts the specified file into that device array.
9. Click OK to generate the components of the unload job. The Unload Job window reappears, with the components of the job completed.
10. Click Save to save this Unload Job. You can click Run to run the job, or click Cancel to exit and run the job later.
11. To run the job, click Run and the Active Job window appears.
12. When the Active Job window displays `Job Completed`, click Cancel to return to the main HPL window.

Generate from the Components menu

To generate all of the components for both load and unload jobs in one operation, choose Components > Generate Job from the main HPL window. This Generate option lets you choose formats that are not available from the Format-Definition window.

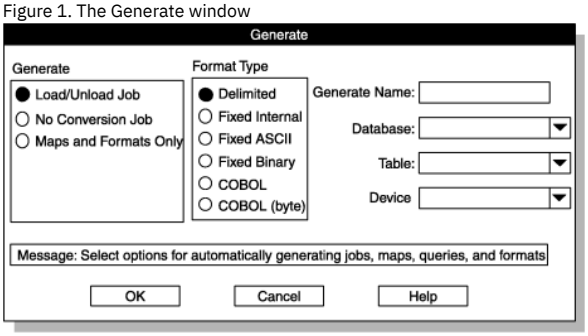
- The Generate window
  You can specify the characteristics of the components that **ipload** creates from the Generate window.
- Generating load and unload components
  When you choose Components > Generate, you can generate all of the components required for a load job and an unload job: format, load map, unload map, query, and device array.
- Using the No Conversion Job option
  The No Conversion Job option uses the IBM® Informix® internal format to unload data from a table. Jobs loaded or unloaded with this option are sometimes called raw loads or raw unloads.

The Generate window

You can specify the characteristics of the components that **ipload** creates from the Generate window.

The following figure shows the Generate window. This window generates all of the components required for a load job and an unload job: format, load map, unload map, query, and device array.

Figure 1. The Generate window



- Generate group
  The Generate group specifies the type of generate to perform.
- Format type group
  The Format Type group specifies the format of the data file.

Generate group

The Generate group specifies the type of generate to perform.

The Generate group has the following choices.

Choice	Effect	See
Load/Unload Job	Generates both load and unload jobs	Generating load and unload components
No Conversion Job	Generates a job that treats an entire database record as one entity	Using the No Conversion Job option
Maps and Formats only	Generates only a format, a load map, and an unload map	

Format type group

The Format Type group specifies the format of the data file.

The Format Type group has the following choices.

Choice	Description	See
Delimited	The fields of a data-file record are separated by a field delimiter, and records are separated by a record delimiter. The default delimiter for fields is a vertical bar (|). The default delimiter for records is a new line.	Modifying delimited-format options
Fixed Internal	The data file uses IBM® Informix® internal format. The only changes to the data that you can make when you use this format are ALTER TABLE changes: modify the order of columns, delete or add columns, or change the data type. The HPL loads and unloads data in this format more efficiently than data in the Delimited and Fixed ASCII formats.	Other formats
Fixed ASCII	All records are the same length. Each record contains characters in fixed-length fields. This format is the same as the Fixed format choice of the Record Formats window.	Fixed-length records
Fixed Binary	The data file records contain data in fixed-length fields. Character-oriented data is in character fields. Numeric data (integer, float, and so on) is in machine-dependent binary values. Use this format for loading or unloading data for an application that has or requires data in binary format. Data in binary format is much more compact than data in ASCII format.	Fixed-length records
COBOL	The data file is formatted according to COBOL 86 standards. All COBOL data types are supported.	COBOL records
COBOL (byte)	The data file is formatted with byte alignments for COMP-4 data type. All COBOL data types are supported.	

Tip: To generate EBCDIC data, select the Delimited or Fixed ASCII format and use the format options to change the code set.

Alter the schema of a table

Generating load and unload components

When you choose Components > Generate, you can generate all of the components required for a load job and an unload job: format, load map, unload map, query, and device array.

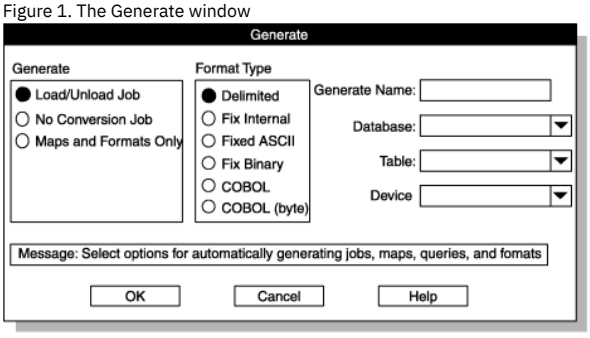
To generate the components for loading or unloading a database:

1. Choose Components > Generate Jobs from the main HPL window to display the Generate window.
2. Click Load/Unload Job in the Generate group.
3. Select a format for the data file in the Format Type group.
4. Select a name for the generated components and type it in the Generate Name text box. This name is used for each of the components that this option creates.
5. Type the name of the database that you will load or unload in the Database text box. Or, click the down arrow to select a database from the selection list.
6. Type the name of the table within the database in the Table text box. Or, click the down arrow to select a table from the selection list.
7. Type the name of a device array in the Device text box. Or, click the down arrow to select a device from the selection list.
   If you enter the name of a device (file) instead of a device array, **ipload** creates a device array of the same name as the unload job and inserts the specified device into that device array.

   When you specify a file instead of a device array in the Device text box, **ipload** makes the following assumptions about the data file:
   - The file is an ASCII file.
   - The file uses the same locale as the database.
   - The file uses a vertical bar (|) for the field delimiter and a new line for the record delimiter.
   - The fields in the data file are in the same order as the columns of the target table.
8. Click OK.

The following figure shows appropriate choices for generating load and unload jobs for delimited output from the **state** table of the **stores_demo** database. After **ipload** creates the components, you can run the job or use the Component-Definition windows to make any necessary changes.

Figure 1. The Generate window



For information about generating a job from a .csv file, see Testing the import of a CSV file.

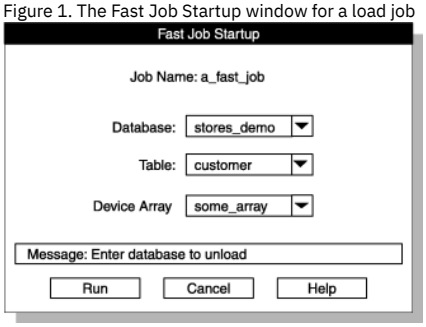
Using the No Conversion Job option

The No Conversion Job option uses the IBM® Informix® internal format to unload data from a table. Jobs loaded or unloaded with this option are sometimes called raw loads or raw unloads.

The No Conversion Job option treats an entire database record as one entity by using the internal format. It does not generate formats or maps. The No Conversion Job option is the fastest option that you can use for loading and unloading data. Use this option to transport data or when you need to reorganize the disks on your computer. No-conversion jobs are always completed in express mode. You cannot use the **onpload** command line to convert the running job to deluxe mode when using a no-conversion job.

When you run a job that you created with the No Conversion Job option, **ipload** displays a Fast Job Startup window instead of the usual Load Job or Unload Job window.

To use the Fast Job Startup window:

1. Choose Components > Generate Job from the main HPL window.
2. Click No Conversion Job in the Generate group.
3. Select a name for the job and type it in the Generate Name text box.
4. Type the names of the database, table, and device array in the Database, Table, and Device text boxes.
5. Click OK. The display returns to the HPL main window.
6. Choose JobsLoad (or Jobs > Unload) from the main HPL window.
   The Load Job Select or Unload Job Select window appears.
7. Select the job from the Job Information list box.
8. Click OK.
   The Fast Job Startup window appears, as the following figure shows.
   Figure 1. The Fast Job Startup window for a load job
   


9. Click Run to run the job and the Active Job window appears.
10. When the Active Job window displays `Job Completed`, click Cancel to return to the main HPL window.

The HPL browsing options

This section describes the browsing options that are available for the High-Performance Loader (HPL).

- Browsing options
  Use the browsing options of the High-Performance Loader (HPL) to preview records from the data file, review records after you perform a load or unload job, review various files associated with the HPL, and view the status of a load or unload job.

Related reference:
Problems during an unload job
Problems during a load job

Browsing options

Use the browsing options of the High-Performance Loader (HPL) to preview records from the data file, review records after you perform a load or unload job, review various files associated with the HPL, and view the status of a load or unload job.

- Preview data-file records
  Before you actually run a load job, you can use the Record Browser window to check your definition of the format. The display shows errors such as incorrect field lengths or missing fields. You can edit the format to correct your format definitions.
- Reviewing records that the conversion rejected
  When you run a load job, **onpload** creates a file that contains information about records of the data file that the conversion rejected.
- Viewing the violations table
  The load job also creates two tables in the target database that contain information about records that passed the conversion but that the database server rejected. The tables are named ***tablename*_vio** and ***tablename*_dia**, where *tablename* is the name of the table being loaded.
- View the status of a load job or unload job
  When a load or unload job is complete, **onpload** writes a record of the load or unload job into a log file.

Using the Record Browser window

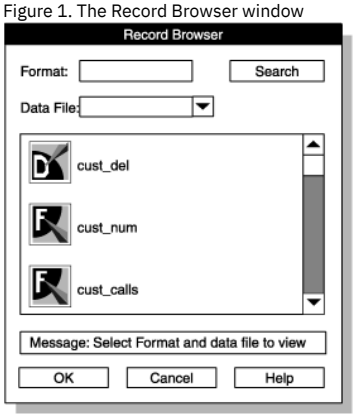
You can review records in a specified format, search the list of available formats, or edit a format from the Record Browser window.

- Reviewing data-file records in a selected format
- Searching and editing a format
- Editing a format

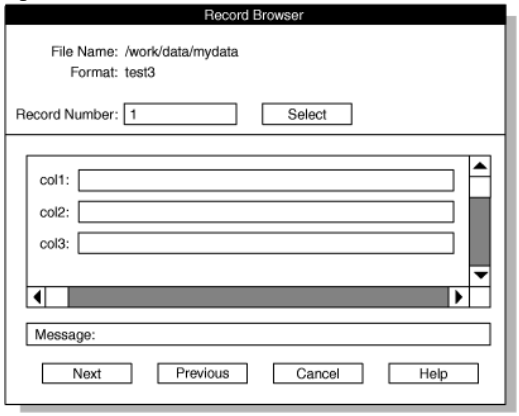
Reviewing data-file records in a selected format

To review data-file records in a selected format:

1. In the HPL main window, select the project that contains your load job.
2. Choose Browsers > Record.
   The Record Browser window appears, as the following figure shows.
   Figure 1. The Record Browser window



3. Type the name of the format to be applied to the source data file or click the format name in the list box.
4. In the Data File text box, type the name of the data file that you plan to load, or click the down arrow and select a file from the selection list.
5. Click OK.
   The second Record Browser window appears, as the following figure shows. This Record Browser window displays each of the fields in the format, followed by the value of the field for the given Record Number.
   Figure 2. The Record Browser window



6. You can take the following actions:
   - Type the record number that you want to view. Click Select.

- Click Next to display the next record.
- Click Previous to display the previous record.

7. When you finish browsing, click Cancel to return to the HPL main window.

Searching and editing a format

To search for and edit a format:

1. In the HPL main window, select the project that contains your load job.
2. Choose Browsers > Record to display the Record Browser window.
3. In the Format text box, type the format name or partial format name that you want to find. You can use wildcards (for example, *`cust`*).
4. Click Search. The **ipload** utility displays all formats of the current project that include the letters *cust*.
5. Click Cancel to return to the HPL main window.

Editing a format

To edit a format:

1. Select the project that contains your load job.
2. Choose Browsers > Record from the HPL main window.
3. Click a format button to edit the format. The **ipload** utility displays the Format-Definition window.

Editing a format

Reviewing records that the conversion rejected

When you run a load job, **onpload** creates a file that contains information about records of the data file that the conversion rejected.

This file is named *basename*.rej where *basename* is the base name that you selected in step 7 of Creating a load job. When you use a generate option to create the components for a load job, *basename* is /tmp/*jobname* where *jobname* is the name that you selected for the unload job.

To review rejected records:

1. On the HPL main window, select the project that contains your load job.
2. Choose Browser > Record to display the Record Browser window.
3. Type the name of the format to be applied to the rejected-records file in the Format text box. Or, click the format name in the list box.
4. Type the name of the rejected-records file in the Data File text box. Or, click the down arrow and select a data file from the selection list.
5. Click OK to display the second Record Browser window.
6. You can take the following actions:
   - Type the record number that you want to view. Click Select.
   - Click Next to display the next record.
   - Click Previous to display the previous record.
7. Click Cancel to return to the HPL main window.

Viewing the violations table

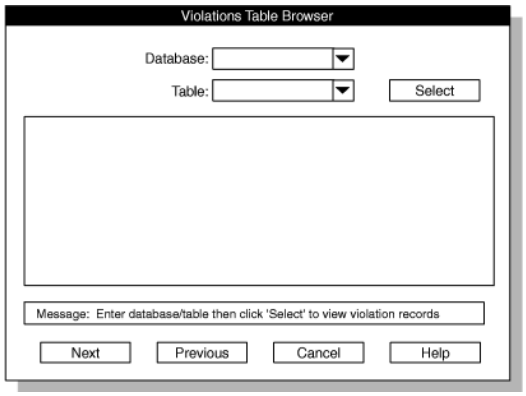
The load job also creates two tables in the target database that contain information about records that passed the conversion but that the database server rejected. The tables are named ***tablename*_vio** and ***tablename*_dia**, where *tablename* is the name of the table being loaded.

View the violations table to browse through records that passed the filter and conversion but that the database server rejected. The High-Performance Loader (HPL) writes these records into the violations table (***tablename*_vio**). The data in the violations table has the same format as the database table.

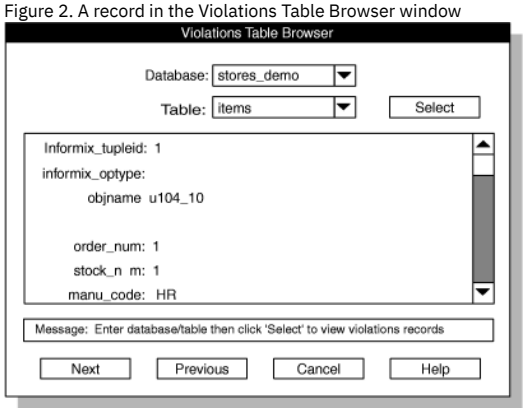
The *IBM® Informix® Guide to SQL: Syntax* discusses in detail the information found in the violations table.

To view the violations table:

1. Choose Browsers > Violations from the HPL main window.
   The Violations Table Browser window appears, as the following figure shows.
   Figure 1. The Violations Table Browser window



2. Type the name of the database and table that you want to review the violations or click the down arrows to make your choices from selection lists.
3. Click Select.
   The following figure shows the first record of a violations table.
   Figure 2. A record in the Violations Table Browser window



4. Click Next and Previous to move forward and backward through the violations table.
5. Click Cancel to return to the HPL main window.

View the status of a load job or unload job

When a load or unload job is complete, **onpload** writes a record of the load or unload job into a log file.

- Viewing the log file
  The default name for a log file is /tmp/*jobname*.log, where *jobname* is the name that you chose for the job. You can specify a different name for the log file in the Load Job window or Unload Job window.
- Sample log file

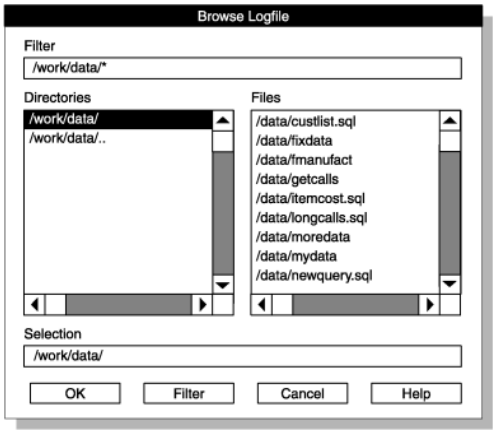
Related reference:
Run the unload job
The HPL log-file and pop-up messages

Viewing the log file

The default name for a log file is /tmp/*jobname*.log, where *jobname* is the name that you chose for the job. You can specify a different name for the log file in the Load Job window or Unload Job window.

To view the log file:

1. Choose Browsers > Logfile from the HPL main window.
   The Browse Logfile window appears, as the following figure shows. When the window appears, the Filter text box and the Selection text box show the directory from which **ipload** was started.
   Figure 1. The Browse Logfile window



2. In the Filter text box, type the full path name of the directory that contains the log. You can use wildcards to select only certain files from that directory.
3. Click Filter.
   The Files list box shows a list of the files that match the path that you entered in the Filter text box.
4. In the Files list box, click the name of the file that you want to examine. The full path name of the selected file appears in the Selection text box.
5. Click OK.
   A Browse window appears that displays the contents of the selected file.
6. Review the log with the scroll bar to move through the log.
7. Click Cancel to return to the HPL main window.

Alternatively, if you know the full path name of the log file, you can simply type the path name in the Selection text box and click OK.

Sample log file

The following example shows a sample log file entry:

```
Sat Mar 11 13:52:42 1995

Session ID 1

Unload Database -> stores_demo
Query Name  -> f_manufact
Device Array-> fmanufact
Query Mapping-> f_manufact
Query-> select * from manufact
Convert Reject  -> /work/data/f_manu_unl

Database Unload Completed -- Unloaded 9 Records  Detected 0 Errors

Sat Mar 11 13:52:50 1995
```

You can review the log file to determine load status and to see where any errors occurred. The log file is a simple ASCII file. You can print it if necessary.

Manage the High-Performance Loader

- Manage modes, errors, and performance
  When you manage the High-Performance Loader (HPL), you manage modes, violations (errors), and performance. You also need to avoid the limitation that occurs when using an Excalibur Text DataBlade module index
- HPL modes
  The High-Performance Loader (HPL) offers two load modes, deluxe mode and express mode, and one unload mode. The express mode is faster, and the deluxe mode is more flexible.
- HPL load and unload errors
  When you load records from a data file, some of the records might not meet the criteria that you established for the database table.
- HPL performance
  You can improve the HPL performance by preparing an environment that is optimized for the particular load or unload job that you are performing.
- Limitation when using the Excalibur Text DataBlade Module indexes
  You cannot create a load job with multiple devices to insert rows into a table that has an Excalibur Text DataBlade module index. A multiple-device load fails because the Excalibur Text DataBlade module does not handle concurrency correctly.

HPL loading modes

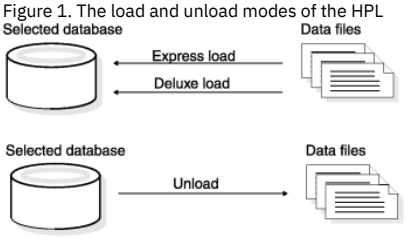
Manage modes, errors, and performance

When you manage the High-Performance Loader (HPL), you manage modes, violations (errors), and performance. You also need to avoid the limitation that occurs when using an Excalibur Text DataBlade module index

HPL modes

The High-Performance Loader (HPL) offers two load modes, deluxe mode and express mode, and one unload mode. The express mode is faster, and the deluxe mode is more flexible.

The following figure shows the load and unload modes of the HPL.
Figure 1. The load and unload modes of the HPL



- The HPL deluxe mode
- The HPL express mode
  The express mode for loading is faster than the deluxe mode, but has some limitations
- How the express and deluxe modes work

Related concepts:
Express-mode limitations

The HPL deluxe mode

The deluxe mode has the following features:

- Performs row-by-row referential and constraint checking as the data is loaded
- Allows loading of data while other users are working (no table locking) if the table already has an associated violations table before the load and if either of the following conditions apply:
  - The index is set to FILTERING WITHOUT ERROR mode
  - The table does not have unique indexes.
- Allows users to access and update the table during a load
  Loaded data is immediately visible to the user.

- Logs data, but also offers a no-logging option
- Updates indexes
- Evaluates triggers
- Sets constraints to FILTERING WITHOUT ERROR
- Sets the isolation mode as if for an insert cursor
- Simulates an INSERT statement, except that the HPL allows the load to handle parallel data streams
- Allows loading of data without replication

The deluxe mode has the following limitations:

- Does not support loads without conversion
- Does not support loads that have conversion but do not generate a violations table
- Does not support the **-fv** option

When you use the deluxe mode without replication to load data into the table that was used to define the replicates, the data in that table is not replicated.

Related concepts:

How the express and deluxe modes work
The onpload utility deluxe-mode process
Comparison between an express-mode and a deluxe-mode load operation

The HPL express mode

The express mode for loading is faster than the deluxe mode, but has some limitations

The express mode has the following features:

- Locks tables for exclusive use by the load utility
- Disables referential and constraint checking on the table
- Requires a level-0 backup
- Sets all objects (such as indexes or constraints) to disabled before loading
- Re-enables all objects after loading, if possible, and flags objects that cannot be re-enabled in the violations and diagnostic tables
- Supports loading of raw tables
- Supports the loading of logged databases and ANSI mode databases
  However:
  - If you load ANSI mode databases in express mode, you cannot use DB-Access to select data from the database tables.
  - If you load logged databases in express mode, you must perform a level-0 backup before you can write to the target database.

The express mode does not support:

- Tables that contain smart large objects (BLOB or CLOB data types)
- Tables that contain simple large objects (TEXT and BYTE) or extended data types
- Loading of data on a heterogeneous data replication (HDR) replicated table from a database that has transactions
- A table that has a fragmentation strategy and has a WITH ROW IDs clause to enable by using row IDs with fragmentation
- Tables with primary key constraints when child table records refer to the load table
- Rows that are larger than the system page size
- The static-hash access method
- Triggers on the loaded data, because express mode cannot invoke the triggers

Important: If your load job has any of these conditions, you must use deluxe mode to load your data.
Related concepts:

How the express and deluxe modes work
The onload utility express-mode load process
Express-mode limitations
Comparison between an express-mode and a deluxe-mode load operation

How the express and deluxe modes work

A deluxe-mode load simulates an INSERT statement, except that the High-Performance Loader (HPL) allows the load to handle parallel data streams.

The sequence of events when you run an express-mode load is as follows:

1. The **onload** utility locks the table with a shared lock.
   Other users can read data in existing rows.
2. The **onload** utility creates new extents and fills them with the new rows. However, **onload** does not update the database structures that track extents.
   The new extents are not visible to the user.
3. At the end of the express load, **onload** updates the internal structures of the database.
4. The **onload** utility sets the table to read-only.
   This setting occurs because in express mode **onload** does not log data, and therefore, the table is in an unrecoverable state.
5. The **onload** utility unlocks the table and enables the constraints. The new rows become visible to the user for read only.
6. The user performs a level-0 backup.
7. Your database server sets the table to read/write.

If the load fails, **onload** discards the extents and clears the internal information that says the table is unrecoverable.

- Foreign-key constraints
  Express® mode cannot disable primary constraints or unique constraints that are referenced as foreign keys that are active on other tables. If you want to load data into such a table, you must first use SET CONSTRAINTS DISABLED statements to disable the foreign-key constraints in the referencing table or tables. After the load is finished, re-enable the foreign-key constraints.

The INSERT statement

Foreign-key constraints

Express® mode cannot disable primary constraints or unique constraints that are referenced as foreign keys that are active on other tables. If you want to load data into such a table, you must first use SET CONSTRAINTS DISABLED statements to disable the foreign-key constraints in the referencing table or tables. After the load is finished, re-enable the foreign-key constraints.

The following figure shows an example of foreign-key constraints. The table **target** has a primary key (**thePK**) and a unique key (**unique**) that table **blue** and table **green** reference. Before you perform an express-mode load into the table **target**, you must disable the foreign-key constraints in both table **blue** and table **green**.
Figure 1. Foreign-key constraints

HPL load and unload errors

When you load records from a data file, some of the records might not meet the criteria that you established for the database table.

For example, the data file might contain:

- Null values where the table specifies NOT NULL
- Values in an incorrect format (for example, alphabetic characters in a numeric field)
- Records that do not have the expected number of fields

The way that the HPL treats these errors depends on the mode (deluxe or express) and the type of job (load or unload).

The HPL separates errors into the following two classes:

- Rejected records from the input file
  These records include:
  - Records that the filter rejected
  - Records that cannot be converted
- Constraint violations

- Rejected records from the input file
  Input-file records that the High-Performance Loader (HPL) rejects because they could not be converted include records in an incorrect format, records that do not have the expected number of fields, and records whose fields contain null values for columns that do not allow null values.
- Constraint violations
- View error records
  Choose from the Browsers menu in the HPL main window to view the error records that **onpload** generates.

Rejected records from the input file

Input-file records that the High-Performance Loader (HPL) rejects because they could not be converted include records in an incorrect format, records that do not have the expected number of fields, and records whose fields contain null values for columns that do not allow null values.

The **onpload** utility writes these records into a file with the suffix .rej. The **onpload** utility writes records that are rejected because they do not match the filter criteria into a file with the suffix .flt.

Constraint violations

When the **onpload** utility starts a deluxe-mode load, it runs the following SQL statement:

```
SET CONSTRAINTS ON mytable FILTERING
```

This statement has two results:

- The utility adds two tables, **mytable_vio** and **mytable_dia**, to the database that contains **mytable**.
- All of the constraints that are associated with the table are set to filtering. Filtering mode causes any record that does not meet the constraint requirements to be added to the **mytable_vio** table instead of generating an error.

The use of filtering mode for constraints is covered in detail in the *IBM® Informix® Guide to SQL: Syntax*.

View error records

Choose from the Browsers menu in the HPL main window to view the error records that **onpload** generates.

Browsing options

HPL performance

You can improve the HPL performance by preparing an environment that is optimized for the particular load or unload job that you are performing.

You must consider the following aspects of your load and unload jobs:

- Configuration-parameter values
- Mode (express or deluxe)
- Devices for the device array
- Usage models

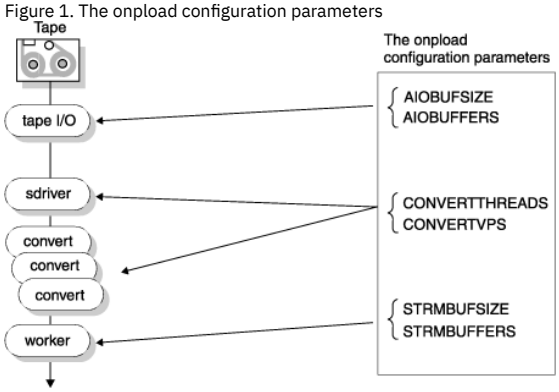
- The onpload configuration parameters
  The **onpload** configuration parameters control the number of threads that **onpload** starts and the number and size of the buffers that are used to transfer data.
- Express-mode limitations
- The onstat options for onpload
  The **onstat** utility has two options that you can use to observe the behavior of database server threads during express-mode loads.
- Devices for the device array
  On a data-load job, each device runs independently of other devices. Thus mixing fast and slow devices does not adversely affect the speed of the load.
- HPL usage tasks
- Settings for a no-conversion load or unload job
  A no-conversion load or unload is not highly CPU intensive because no conversion is involved. In this case, the load or unload is expected to be limited by the speed of the tape devices. No-conversion loads and unloads are always completed in express mode.
- An express-mode load with delimited ASCII
  In an express-mode load with delimited ASCII, the load or unload job is limited by the available CPU. The conversion to or from IBM® Informix® types to ASCII is the most expensive portion of these operations
- HPL performance hints
  In general, the performance of the High-Performance Loader (HPL) depends on the underlying hardware resources: CPU, memory, disks, tapes, controllers, and so on. Any of these resources could be a bottleneck, depending on the speed of the resource, the load on the resource, and the particular nature of the load or unload.

Related reference:
Configure the ipload utility

The onpload configuration parameters

The **onpload** configuration parameters control the number of threads that **onpload** starts and the number and size of the buffers that are used to transfer data.

The following figure shows which part of the **onpload** process is affected by each configuration parameter.
Figure 1. The onpload configuration parameters



The AIOBUFSIZE and AIOBUFFERS parameters control the number and size of the buffers that **onpload** uses for reading from the input device. CONVERTTHREADS and CONVERTVPS control the amount of CPU resources to apply to data conversion. STRMBUFFSIZE and STRMBUFFERS control the number and size of the buffers used to transport data between **onpload** and the database server.

The **onpload** configuration parameters are stored in the following files:

- $INFORMIXDIR/etc/$PLCONFIG (UNIX)
- %INFORMIXDIR%\etc\%PLCONFIG (Windows)

Related reference:
HPL usage tasks
HPL performance hints

High-Performance Loader configuration file

Express-mode limitations

You cannot use express mode in certain situations. For example, express mode does not support the loading of simple large objects (Simple LOs) or Ext Type Data and smart-large-object data (Ext Type data types), ensuring constraints, or invoking triggers.

In addition, you cannot use DB-Access to select data from ANSI database tables if the data was loaded in express mode. If you attempt to select data from such tables, the database server rejects the SELECT statements because the tables were not archived. Only read-only access is allowed to the tables until a level-0 archive is performed.

Related concepts:
The HPL express mode
HPL modes

The onstat options for onpload

The **onstat** utility has two options that you can use to observe the behavior of database server threads during express-mode loads.

Use the following command to display light-append information:

```
onstat -g lap
```

The **onstat -j** option provides an interactive mode that lets you gather special information about an **onpload** job.

Related reference:
The onstat -j option

Devices for the device array

On a data-load job, each device runs independently of other devices. Thus mixing fast and slow devices does not adversely affect the speed of the load.

In most unload jobs, all devices receive equal amounts of data. Thus the speed of all devices is limited by the speed of the slowest device. If you have several fast devices and one or two slow devices, it might be advantageous to remove the slow devices.

When CPU resources are plentiful during an HPL job, the device controllers are a potential bottleneck. If you have configured extra converter threads and extra converter VPs, CPU use should be close to 100 percent. If CPU use is not close to 100 percent, the cause might be one of the following situations:

- The device controller is managing too many devices.
- The devices themselves are slow.

Related reference:
Define device arrays

HPL usage tasks

Three tasks that you might need to perform for the High-Performance Loader (HPL) are:

- Reorganizing computer configuration
- Altering the schema of a table
- Assessing information for loading or unloading external data

- Reorganize computer configuration
  If you are not changing the table schema, use a No-Conversion Job to unload and load when you need to reorganize the configuration of your computer or change to a different computer. The no-conversion mode is the fastest means of performing an unload job or a load job, because rows are unloaded in IBM® Informix® internal format with no conversion and reloaded in the same fashion.
- Alter the schema of a table
  When you need to alter a table (add, drop, or change the data type of columns), use the Fixed Internal format. In Fixed Internal format, rows are unloaded in IBM Informix internal format on a column-by-column basis. Thus you can drop, add, or modify columns and still minimize conversion overhead.
- Assess information for loading or unloading external data
  When you load or unload data from an external source, you must assess the type of data and the amount of conversion that is required so that you can choose appropriate configuration parameters.

Related concepts:
The onpload configuration parameters

Reorganize computer configuration

If you are not changing the table schema, use a No-Conversion Job to unload and load when you need to reorganize the configuration of your computer or change to a different computer. The no-conversion mode is the fastest means of performing an unload job or a load job, because rows are unloaded in IBM® Informix® internal format

with no conversion and reloaded in the same fashion.

Restriction: You cannot use a No-Conversion Job when the source and target computers use different internal byte representations. For information about the byte-order type, see The Machines window.
For information about preparing for a no-conversion unload/load with **ipload**, see Using the No Conversion Job option. To set no-conversion mode when you are using the **onpload** utility at the command line, use the **-fn** option. For more information, see The onpload utility.

Alter the schema of a table

When you need to alter a table (add, drop, or change the data type of columns), use the Fixed Internal format. In Fixed Internal format, rows are unloaded in IBM® Informix® internal format on a column-by-column basis. Thus you can drop, add, or modify columns and still minimize conversion overhead.

Related reference:
Format type group

Assess information for loading or unloading external data

When you load or unload data from an external source, you must assess the type of data and the amount of conversion that is required so that you can choose appropriate configuration parameters.

The following sections show possible configuration parameters for two different types of load jobs. Suppose your hardware has the following configuration:

- Eight CPU symmetric multiprocessors, each about 40 MIPS
- Several (say 16) 300-MB disks (for the database)
- Four 1.2-MB tape devices (to load to and unload from)
- 512-MB memory

You also have this information about your system:

- The database server is running with seven CPU virtual processors.
- The data that you want to load has a row of about 150 bytes with a mix of **INT**, **DATE**, **DECIMAL**, **CHAR**, and **VARCHAR** data types. (This is similar to the LINEITEM table in the TPC-D database).

Settings for a no-conversion load or unload job

A no-conversion load or unload is not highly CPU intensive because no conversion is involved. In this case, the load or unload is expected to be limited by the speed of the tape devices. No-conversion loads and unloads are always completed in express mode.

The following table lists sample values of configuration parameters for a raw load.

Configuration parameter	Suggested value	Comment
CONVERTVPS	4	This process is not CPU intensive.
CONVERTTHREADS	1	This process is not CPU intensive.
STRMBUFFSIZE	128	Choose some multiple of the AIOBUFSIZE, up to about 8*AIOBUFSIZE.
STRMBUFFERS	5	Should be CONVERTTHREADS + 4.
AIOBUFSIZE	32	Choose a buffer size to match the best block size for the tape drive. Large buffers increase performance if sufficient memory is available.
AIOBUFFERS	5	CONVERTTHREADS + 4 or 2 * CONVERTTHREADS, whichever is larger

- Run no-conversion load jobs with tables with hidden columns
  If you run no-conversion jobs, the physical image of the table in the load file must match the physical image of the target table and all columns must exist in the same order and be of the same type.

Related tasks:
Using the No Conversion Job option

Run no-conversion load jobs with tables with hidden columns

If you run no-conversion jobs, the physical image of the table in the load file must match the physical image of the target table and all columns must exist in the same order and be of the same type.

By default a no-conversion unload job does not contain the hidden columns, because the job resulted from unloading a "SELECT *" query and this type of SELECT query does not return any hidden columns. Under these circumstances, the target table where the load will occur must not contain any hidden columns. If it does contain hidden columns, the image of the file will not be a match.

If your application requires that the unload file contains the hidden columns (for example, if the target table has hidden columns and it is not possible to alter the table to remove the columns while the load occurs) , you must use a SELECT statement that explicitly indicates the columns in the select list.

The target table should not contain hidden columns, because these columns retain internal information for internal activities of the engine. Loading hidden columns can create unexpected results.

Hidden columns tables include but are not restricted to fragmented tables with rowid columns, tables with VERCOLS, and tables with CRCOLS. Also fragmented tables with rowid columns do not support no-conversion jobs.

An express-mode load with delimited ASCII
